Introduction

This report presents and summarizes the results of 1883 Mobile-Metal Ion sampling program completed by Planet Exploration Inc. and Goldcorp Inc. on the Sidace Lake property in Sobeski Lake Area, Blackbear Lake Area, Coli Lake Area, and Nungesser Lake Area.

The geochemical sampling program was completed during the periods of June 23, 2003 and July 26, 2003. Samples were collected off of roads, trails, grid lines, and GPS lines through clear cut areas. Samples collected along grid lines were brushed out and repicketed.

Patrie Exploration Services of Massey, Ontario, undertook the soil sampling. Pascal Chantigny of Cochenour, Ontario and Ottawa, Ontario, undertook field supervision. Michael Dehn, of Oakville, Ontario, undertook analysis and interpretation of the geochemical results.

Location and Access

The Sidace Lake property is located within the Red Lake Mining Division of the Ministry of Northern Development and Mines, 25 kilometres northwest of Cochenour, Ontario, on NTS sheet 52N05, in Northwestern Ontario (see Figures 1-3).

Figure 1 Location of Red Lake, Ontario

Access is from Highway 105 to Highway 125, existing at Nungessor Road, a paved unassumed logging road that exits north off of Highway 125 between the communities of Cochenour and Balmertown. Approximately 19 kilometres up Nungessor Road the property begins, and access to the center of the property can be obtained by taking the hard based 2 lane Coli Lake Road, which heads east off of Nungessor Road and traverses the property beyond its eastern most extent. Many primary and secondary logging roads traverse the property (see Figure 4).

Some parts of the property are covered by small lakes and wide swamps as well as several small creeks. Access is extremely good for an exploration property.

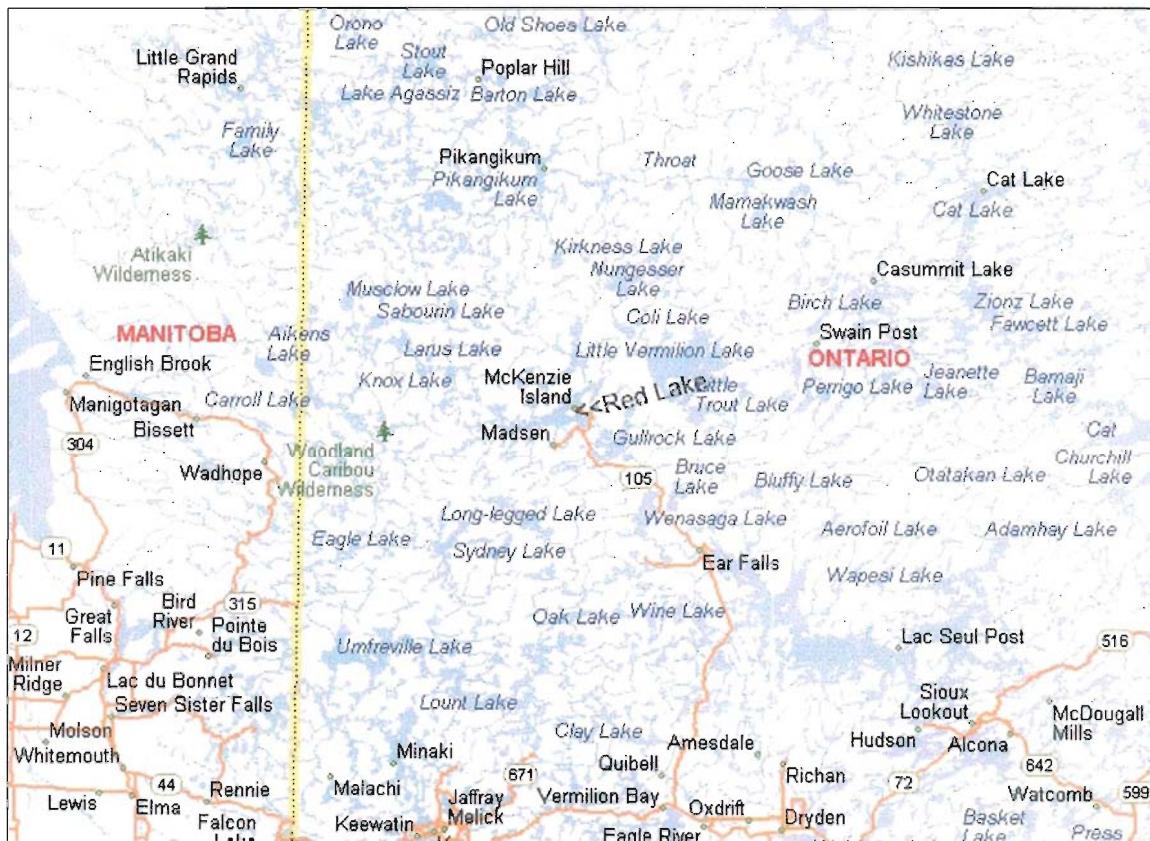

Figure 2 Location of Red Lake in northern Ontario

Claims and Ownership

The Sidace Lake Property consists of 71 staked claims comprising in excess of 32,000 contiguous acres (see figure 4). A list of claims is found in Table 1. All claims are 100% Planet Exploration Inc, even if otherwise stated in the list. Goldcorp Inc. is earning a 50% interest in the claims after reaching certain expenditure and property payment thresholds.

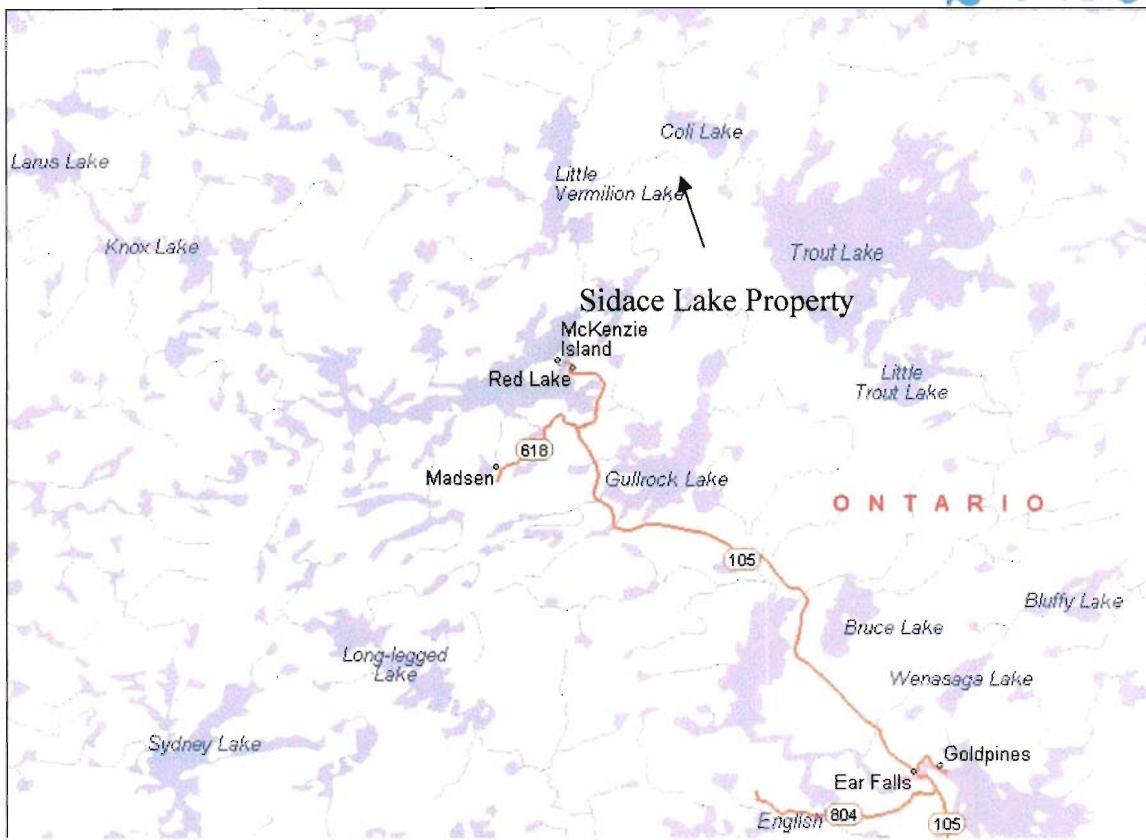

Figure 3 Location of Sidace Lake Property

Previous Work

There is very limited previous work on the property. There is no known previous lithogeochemical or soil geochemical survey on the property. The area that is covered by the property has never been mapped by the OGS or GSC at any scale better than 1:50,000.

The first recorded work on the area that the property covers is ground and airborne geophysics completed in the late 1970's to the early 1980's with follow up drilling of conductors searching for base metal occurrences.

The predecessor to Planet Exploration Inc. completed some RC drilling with very encouraging gold grain anomalies, in the late 1990's. This was followed up by diamond drilling and a small mapping program (1998-1999) and a small ground geophysical survey.

It wasn't until 2002 and early 2003 that the property had some significant drilling and some significant exploration success. Goldcorp Inc. optioned the property from Planet Exploration Inc. in early 2003.

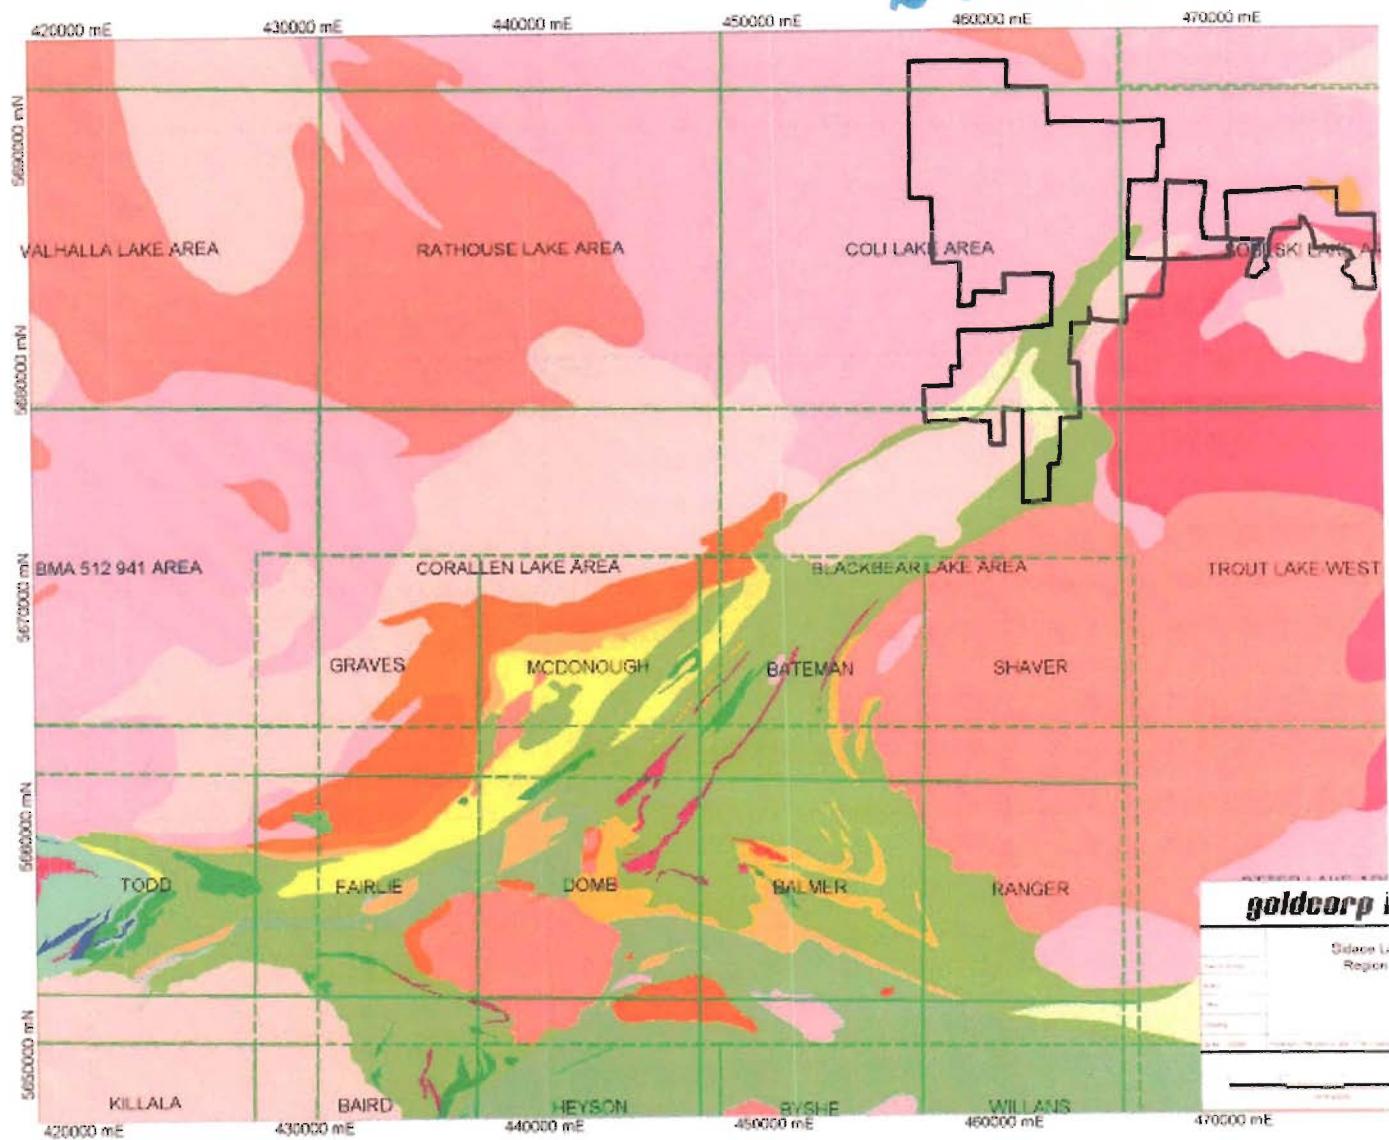

Figure 5 Sidace Lake Property and Regional Geology

Regional Geology

The Red Lake Greenstone Belt is a volcanoclastic assemblage of Archean age rocks that form part of the larger Uchi Subprovince of the Superior Craton. The belt is subdivided into several sequences based primarily on compositional and tectonic characteristics, and it is believed that the ages of some of the assemblages may be picking up later metamorphic events and not primary events. With that in mind, using common nomenclature, the assemblages that seem to most resemble the Sidace Lake Property are:

- The volcano-dominated Balmer assemblage (2.99 Ga), which is most commonly identified in the south central portion, and eastern portion of the main Red Lake Greenstone Belt and the north western portion of the Birch-Uchi Greenstone Belt (Skinner township). GSC Gravity data over the main Red Lake Greenstone Belt and the northern portion of the Sidace Lake Property implying the Property is underlain by a thick sequence of Archean greenstone that is overlain by felsics intrusives and gneiss'.
- The Ball assemblage (2.94-2.92 Ga) at the western end of the Red Lake Greenstone Belt, which is synonymous with the Siderock Lake/Wallace Lake geology at the east end of the Rice Lake Greenstone Belt shares many similarities with the felsics and sedimentary rocks found on the Sidace Lake Property, including limestone/marble horizons.
- The Bruce Channel assemblage (2.89 Ga) found extensively around the Cochenour Mine and the Red Lake and Campbell Mines composed of mafic volcanic flows, felsic pyroclastics and a thick sequence of "Timiskaming-like" sediments including iron formation.

Work Program Summary

Dan Patrie Exploration Ltd. Of Massey Ontario completed the grid line rehabilitation and undertook the MMI geochemical survey between June 23, 2003 and July 26, 2003. All grid line stations and off grid line stations also had GPS coordinates collected in NAD 27, UTM Zone 15 coordinates. Stations along the road were actually collected 3m off of the road in the most undisturbed media present.

Dan Patrie Exploration Ltd. undertook MMI media sampling using 2 two-man crews. 1883 analysis were preformed on 895 sample sites. Nine Goldcorp Inc. standards common sand used regularly by Goldcorp Inc. for MMI analysis). Samples were taken at regular intervals using a hand soil auger between 20cm and 30cm depth when possible. The preferred sample media was a mineral soil, but other media types were collected where no mineral soil was present. The sample was described so that it could be easily compared from other samples based on slope, vegetation, soil and moisture. Samples were placed into plastic Whirl-Pak sealed bags. Sample size averaged between 250 and 500g. Field data for each sample was recorded on a custom designed data sheet. Data collected included: sample location in both grid and UTM coordinates (when applicable), sample type, depth, moisture content, slope, vegetation type as well as an attribute field for comments.

Samples were stored, packed in sealed 5 gallon pails at the Goldcorp Inc. core facility at the Cochenour Mine property and shipped via Manitoulin Transport Inc. to SGS-XRAL Laboratories in Don Mills, Ontario.

SGS-XRAL a homogeneous 50 gram split of each sample is taken for each analysis. For each MMI split, 50ml of a diluted MMI solution is added to the sample based on the MMI procedure requested. The sample is placed in a shaker and is shaken for 20 minutes. The sample is allowed to sit in the MMI solution overnight. After the allotted digestion time, the sample is placed in a centrifuge for 10 minutes if needed. The resulting liquid is decanted into a 20-ml test tube, before being processed through the ICP-ES for the final analysis, and the decanted liquid is additionally diluted 10 times (total dilution is 100 times). An internal standard containing 50.0 ppb Re is added to on in every 10 samples. A control sample with known metal values and a blank is sent through the instrument with each batch of samples.

Table 2 – MMI Sample by Procedure

	MMI A	MMI B	MMI F	Total Samples
Field Samples	788	897	179	
Blank Samples	9	9	1	
Total Samples	797	906	180	1883

Conclusions and Recommendations

There are two few samples to get a good representation of the presence or absence of mineralization.

Au, when present, appears to have an affinity for Zn and As, however more analysis is required to prove this.

There appear to be batch errors from the lab, as certain batches of samples seem to have off kilter background values.

MMI does not pick up roaster contamination (from previous work in the camp). MMI does pick up tailings anomalies very strongly (from previous work). MMI picks up drill cutting anomalies strongly.

Thick overburden on the property (in places > 130m!) may be too much for the MMI to penetrate

A detailed geology map at the scale of 1:20,000 must be created in order to assist in the proper interpretation of the results.

Hg, Mo, and As are present in the system and MMI-F is a viable tool to detect these elements.

Au values in drill core should be followed up and validated with new drilling data, and additional MMI should be completed over these values.

MMI-M (multi-element) appears to have success on the adjacent properties and should be tested as the all-in-one solution to MMI A, B and F.

No drilling is recommended based on the MMI results – however gold is known to exist on the property and other techniques show better correlation with gold values (airborne magnetics).

Statements of Qualification

I, Michael A. Dehn, of 1068 Queens Ave, Oakville, certify that

- I am the author of the report
- I graduated from the University of Waterloo with a Bachelor of Science Degree in 1993
- I have been practicing my profession since 1994 and actively involved in mineral exploration and geological mapping since 1990
- I am, and have been an employee of Goldcorp Inc. since 1994
- I do not hold or expect to receive any interest in the property described in this report
- I have been on this property on several occasions since 1999
- I have managed in excess of 12 MMI geochemical surveys in the Red Lake Greenstone Belt since 2000, and Goldcorp Inc. now has a database in excess of 30,000 samples.
- Data from MMI projects have, in the past, been reviewed by Dr. Mark Fedikow, Wamtech Pty Ltd, and IO Geochemistry of Australia

MMI Geochemistry: Overview

Mobile Metal Ion Geochemistry

The Mobile Metal Ion (MMI) Process® is a totally integrated geochemical approach to precious metal, base metal and kimberlite exploration. It uses a weak partial extraction and ICP-MS ultra trace element analysis to improve the conventional geochemical response over buried ore deposits.

MMI anomalies are sharply bounded and, in most cases, directly overlie and define the surface projection of buried primary mineralized zones.

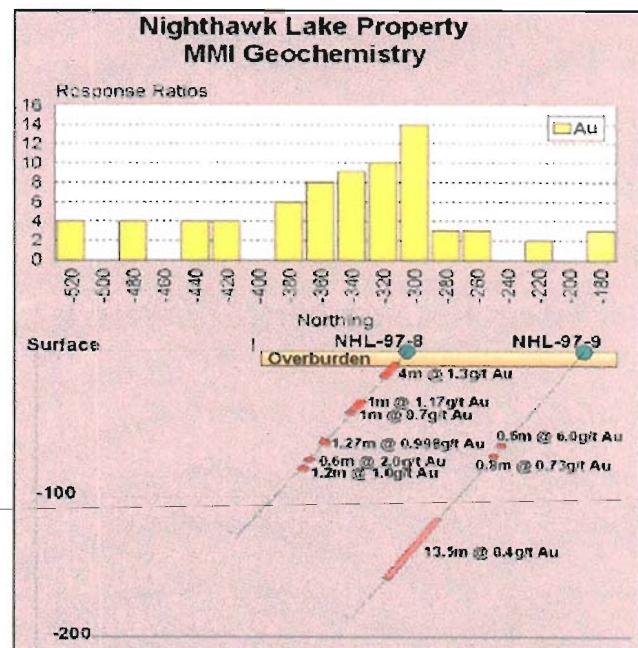

The effectiveness of the MMI Process has been documented in over 1000 case histories on six continents and it has been responsible for numerous commercial successes.

MMI PROCESS®

The MMI Process® consists of:

- simple sample collection procedure in which a 50g sample is collected 10 to 25 cm below the A_o horizon regardless of which soil horizon this depth corresponds to. This sampling depth is critical to the success of method.
- samples are not otherwise prepared or dried
- weak extraction using a multi-component solution to release the mobile ions. There are several extractions possible, and each is specific to various targets or elements.
- high sensitivity ICP-MS analysis which provides part per billion range results
- innovative interpretation using MMI response ratios

The MMI Process® was developed by Wamtech Pty. Ltd in Australia and is performed by exclusive license at SGS Minerals' full service accredited laboratory facilities in Toronto, Ontario, Canada.

Sampling for MMI in Boreal Zones

APPENDIX 5

Mobile Metal Ion Geochemistry

Sampling for MMI in Boreal Climatic Zones

WHERE TO SAMPLE

Experience in MMI sampling in Europe and North America demonstrates that the mobile metal ion geochemical technique works best when samples are collected at a constant depth (10-25 cm) **BELOW** the interface between leaf and twig litter on surface, and completely decomposed material. This sampling interval below the leaf and twig litter can vary from A to B horizon.

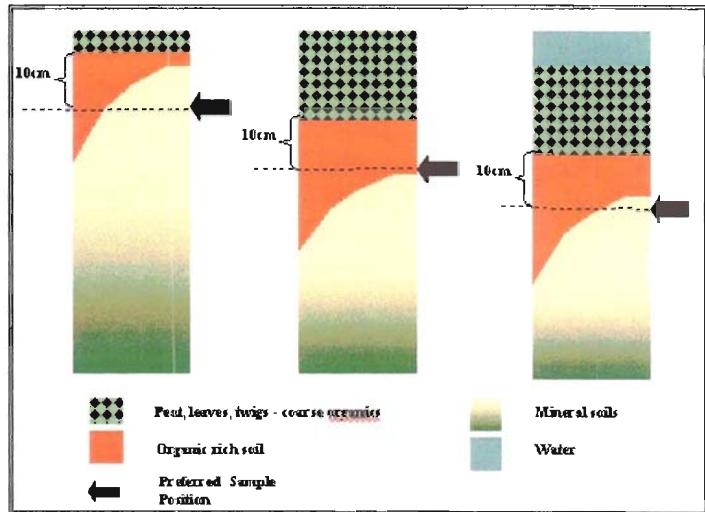

SAMPLING PROCEDURE

To sample for MMI geochemistry in boreal climates, particularly in areas with substrates that contain overlying peat blankets;

- Before actually taking the sample, brush sampling equipment to eliminate residue from previous samples and flush it with soil from the new sample site.
- Scrape away any extensive organic horizon (O or Ao) and eliminate loose non-decomposed matter, debris, and any possible cultural contamination.

- Penetrate the leaf litter and organic material that still has structure (i.e. decomposing leaves, bark, twigs and peat). Once through to a true A-horizon (where the soil resembles a decomposed mass without any obvious leaf or vegetation visible), discard the top 10cm of this A-horizon material and then collect the sample 10 and 25 cm below this horizon.

Diagram at right shows the optimal sampling depths.

- Ensure not to mix organic and inorganic soils in the collected sample. For example, if the material within the 10 to 25 cm zone has a mixture of humus and inorganic soil then proceed to the base of this "mixed zone" and collect the sample from the inorganic material. If the thickness of the humified organic layer exceeds 25 cm then the sample should be collected from the organic layer. Note the soil type in your field description of the site.
- Different soil types may be characterized by variable geochemical backgrounds for some or all elements. To avoid mixing MMI data populations based on soil type, interpret data for organic and inorganic soils separately. If significant differences between soil types are not noted in the lower 25th percentile and background calculations of the data set, then the data populations may be combined for interpretation based on response ratios. For further details on calculating response ratios, please contact an SGS or MMI representative or visit the MMI web site at www.mmigeochem.com.
- During sample collection and handling, no jewelry (watches, rings, bracelets, and chains) should be worn, as this can be a major source of contamination.
- Regardless of topographic influences and associated variability in the soil profile the sample should be collected 10 to 25 cm below the interface with the non-decomposed surface leaf / twig matter.
- Clear and concise notes should be kept at each site, paying close attention to the location of the sample with respect to the thickness and nature of the soil horizons. Parameters such as soil moisture, development of a "b-horizon", organic content, presence or absence of suspended aqueous material within the soil and general characteristics of the overburden in the survey area can be very useful for data interpretation.

Low-level Au Analysis after MMI Extraction

**Technical Bulletin TB09
May 2003**

INTRODUCTION

Analysis of gold on the ICPMS has seen dramatic and consistent lowering of the lower detection limit, from the ppm level in the early 1990's to the ppb level in the late 1990's. For many years the lower detection limit for Au after extraction with MMI-B has been 0.1 ppb. The first few years of the twenty first century have seen further developments in ICPMS instrumentation, both in reliability, and in further lowering of the detection limits for many elements. One of the limiting factors in assessing the practical lower limit of detection, is the ability of the carrier solution to (a) prevent Au from adsorbing and precipitating during the analysis procedure, and (b) to not produce matrix interference with the analysis and measurement procedure. In this regard a number of the licensed laboratories have remarked on the suitability of MMI-B extractant as a carrier for Au during the ICPMS analysis procedure.

The lower detection limit (LDL) of an analytical technique can be defined in a number of ways. In general, the standard deviation (SD) of a number repetitive measurements of a sample will increase with the mean value of the measurements. Many definitions of the LDL are based on the standard deviation near the point where the standard deviation is similar in magnitude to the absolute value. Commonly the LDL is defined as this SD or some multiple (either twice or three times) of it. Consequently, a considerable amount of the material in this document is concerned with determining the standard deviation in repetitive analyses of samples with very low values of contained Au.

INSTRUMENT VERSUS NATURAL BACKGROUND

For many of the exploration programs carried out with MMI-B, the background calculated (usually as the lowest quartile) is above the instrument background, and (correctly) the natural background is used for calculation of response ratios. However, for some exploration programs in areas of deep cover (e.g. desert terrain, or glacial terrain), the background calculated from the lowest quartile uses samples whose reported value is less than 0.1 ppb. For this, the calculation usually assumes a value of 0.05 ppb, or half of the lower detection limit of the instrument. The background calculated is thus partly or wholly influenced by the instrument detection limit. This has an effect on the anomaly contrast within the program. An example showing this is highlighted in Table 1 on page 3.

The samples provided by a client, were from an exploration area in deeply covered terrain in Western Australia, suspected of containing Au mineralization. The client compared MMI-B analyses (Lab C) with those from two other techniques, Labs A and B. The techniques have different levels of extraction. The initial MMI-B figures, with the 0.1 ppb lower detection limit, designated 1DP are shown in the fourth column. Not only is the comparison not flattering to MMI, the lower detection limit has been calculated on an operator imposed lower detection limit (< 0.1 ppb), not the natural background, or in fact the ICPMS limit. The actual ICPMS values from which these were derived, are shown to 3 decimal places, denoted 3DP, in column 5. The real or natural background calculated is now much lower, 0.019 ppb.

The importance of this, in relation to resolution of the Au anomalies is shown in Table 2.

Table 1. Analytical data for client samples for three laboratories.

CWS053	5	8	6	16
CWS055	2	4	4	10
CWS056	3	8	1	5
CWS057	2	2	2	7
CWS058	1	1	1	1
CWS059	2	1	1	5
CWS060	2	1	2	6
CWS061	2	1	2	7
CWS062	2	8	1	5
CWS063	1	1	1	2
CWS064	1	1	1	3
CWS065	1	1	1	2
CWS066	1	1	1	1
CWS067	1	1	1	3
CWS068	1	1	1	2
CWS069	1	1	1	2
CWS070	1	1	1	3
CWS071	2	1	1	3
CWS072	2	16	1	4
CWS073	1	2	1	1
CWS074	3	1	1	5
CWS075	5	12	6	19
CWS076	6	16	8	23

If we compare the MMI data in columns 4 and 5 of Table 2, it is immediately apparent that not only is the resolution of the highest point of the anomaly greater with the 3DP data, there is also better resolution of the 'shoulders'. Whilst the highest response ratios for each of the labs A, B, and C correspond, the MMI analysis, at this level of reporting gives best resolution of the anomalies. The question which needs to be further investigated is how much of this additional instrument resolution can be justifiably reported.

LINEARITY BELOW 1 ppb

To test linearity below 1 ppb, a sample with a known concentration of Au was 'mixed' with various amounts of a 'blank'. Four samples were thus produced with expected Au values of between 0.05 and 0.55 ppb. Each was analysed four times and the mean values plotted, as shown in Figure 1.

Figure 1. Mean Values of average measurements versus expected Au values.

This graph confirms that there is good linearity at sub-ppb levels for the MMI-B method of analysis. The peaks and shoulders referred to in the example above are in this same range, and confirm that the technique could be used for resolution of anomalies of this absolute order, providing the background values are reliable.

REPRODUCIBILITY ON SOLUTION BLANKS

To test the instrument reproducibility, blank MMI-B extraction solutions were analysed by the ICPMS technique in different laboratories at different times. Means and standard deviations for runs of ten blanks at a time are shown below in Table 3.

Table 3. Replicates of blank MMI-B solution.

Sample	1st Run	2 nd Run
MMI-B Blank	0.0134	0.0031
MMI-B Blank	0.0009	0.0054
MMI-B Blank	-0.0077	0.0133
MMI-B Blank	-0.0086	0.0057
MMI-B Blank	-0.0042	-0.0047
MMI-B Blank	-0.0028	-0.0006
MMI-B Blank	0.0031	0.0101
MMI-B Blank	-0.0026	0.0043
MMI-B Blank	-0.0017	0.0009
MMI-B Blank	0.0003	-0.0102
Mean	-0.001	0.00273
Std Deviation	0.0062	0.0068

Whilst it is an important step, analysis of a blank solution is not truly indicative of the entire extraction/analysis procedure.

ANALYSIS OF SOIL SAMPLES WITH LOW Au VALUES

ABSRM09 is a ferruginous sand from a non-gold occurring province in Western Australia. This sample has been used in the past as a 'blank' for Au. In Table 4, the replicate values obtained after digestion of 50 g of this sample with 50 ml of MMIB extractant are shown.

Table 4. Replicate values for extractions with MMI-B from ABSRM09 standard.

Sample	Au (ppb) Lab A	Au (ppb) LabB
ABSRM09	0.1004	0.078
ABSRM09	0.0615	0.062
ABSRM09	0.1297	0.073
ABSRM09	0.0795	0.078
ABSRM09	0.1214	0.067
ABSRM09	0.0598	0.083
ABSRM09	0.0389	0.054
ABSRM09	0.0635	0.067
ABSRM09	0.1108	0.068
ABSRM09	0.0638	0.083
Mean	0.08293	0.0713
Standard Deviation	0.03062	0.0094

Note: The laboratory notation used in this section does not necessarily refer to the same laboratories in other sections.

This result suggests several things. Firstly, the sample does contain a (now) measurable concentration of gold. Secondly, the standard deviation is appreciably lower than the absolute value. Thirdly, even using this sample, the LDL by most definitions is lower than 0.1 ppb. Fourthly, to correctly estimate the LDL, a soil sample with an even lower absolute Au concentration is required.

In general, samples such as this with a small, measurable amount of gold are likely to suffer very badly from the 'nugget effect'. In particular, 50 g samples taken for replicates are likely to contain different numbers of gold particles, which can contribute to the standard deviation. This problem, whilst it exists, is not as acute for the MMI technique in that it is the desorption of small (numerous) surface particles which is targeted. For conventional analysis the 'nugget effect' will produce very high standard deviations at low concentrations.

ANALYSIS OF SILICA SAND

Samples of white silica sand from a commercial sand pit on the Swan Coastal Plain (Bassendean Sand) were sent to several laboratories for replicate Au analysis after extraction with MMI-B. Results are shown in Table 5 below.

Table 5. Replicate analyses of silica sand.

Sample	Au (ppb) Lab A	Au (ppb) Lab B
Silica sand (MMISRM15)	-0.0045	-0.007
Silica sand (MMISRM15)	-0.0047	0.003
Silica sand (MMISRM15)	-0.0233	0.006
Silica sand (MMISRM15)	-0.0190	0.006
Silica sand (MMISRM15)	-0.0205	0.006
Silica sand (MMISRM15)	-0.0352	0.006
Silica sand (MMISRM15)	-0.0227	-0.003
Silica sand (MMISRM15)	-0.0367	-0.011
Silica sand (MMISRM15)	-0.0300	-0.011
Silica sand (MMISRM15)	-0.0276	0.009
Mean	-0.022	0.001
StandardDeviation	0.011	0.007

Note: The laboratory notation used in this section does not necessarily refer to the same laboratories in other sections.

SELECTION OF A LOWER DETECTION LIMIT FOR Au

Skoog and Leary (1992) consider that the minimum distinguishable analytical signal, S_m can be represented as:

$$S_m = S_{bl} + ks_{bl}$$

where S_{bl} is the mean blank signal, s_{bl} is the standard deviation and k is a constant. Some definitions of lower detection limit refer to it being the value of the standard deviation of a blank i.e. when $k = 1$. Raising the value of k for example from 1 to 2 to 3 improves the confidence level of detection; a value of $k=2$ will give a level of confidence of 95%. However, as pointed out earlier, increasing the LDL will reduce the accuracy and sensitivity of the interpretation procedure by creating a higher background. For example, consider a batch of data with a true (natural) background of 0.01ppb. If the laboratory provides an LDL (at (say) a 50% level of confidence) of 0.01ppb, the calculated background calculated will be acceptably close to the true value. If the laboratory quotes the data with an LDL of say 0.03ppb at a higher level of confidence, the calculated background (using the lowest quartile of the data, and half the value of the LDL for values less than the LDL) will be 0.015ppb – an error of 50%. Raising the quoted LDL to 0.1ppb, with an almost 100% level of confidence will result in the calculation of a background of 0.05ppb – an error of 500%. This error carries over from the background value to response ratios calculated from it. It must also be remembered that with the MMI technique we are measuring and averaging a number of very low values (usually 25% of the database) to obtain the background, and this in itself provides an increased level of confidence. From the data above it appears, that for the MMI technique, and particularly for the purpose of obtaining true (natural) backgrounds, an LDL of 0.01 ppb is not inappropriate.

EFFECT OF LDL OF 0.01 ppb Au ON CLIENT PROGRAM

The effect of quoting Au values to 0.01 ppb on the client program (Table 1) is shown in the Table 6 below.

Table 6. Effect of LDL of 0.01 ppb on client's data set.

Sample	Au(ppb)	Au3dp(ppb)	Au2DP(ppb)	Au(RR)	Au3DP(RR)	Au2DP(RR)

CWS 072	-0.1	0.067	0.07	1	3	4
CWS 073	-0.1	0.005	0.005	1	1	0
CWS 074	-0.1	0.091	0.09	1	5	5
CWS 075	0.3	0.348	0.35	6	18	18
CWS 076	0.4	0.421	0.42	8	22	22
B/G (25%)	0.05	0.019167	0.019			
Values in red are those used to calculate background						

The raw data rounded to 0.01 ppb are shown in column 4 of the above table, and the response ratios derived from that data and using a background calculated from the lower quartile of that data are shown in column 7. It is immediately apparent that the data rounded to two decimal places is providing more information than the original data (rounded to one decimal place) and is very similar to that (3DP) for the full instrument capability.

MMI

Manual

For

**Mobile Metal Ion
Geochemical Soil
Surveys**

Version 5.04

Important Information

This **MMI Manual** has been prepared to assist exploration personnel with more effective application of Mobile Metal Ion geochemical surveys. This is the fifth edition of the MMI Process Information Manual, containing the feedback MMI TECHNOLOGY has received and any additional information that it feels is relevant.

To date, the main application for MMI geochemistry has been directed at defining more precise drill targets following directly on from the surface soil sampling phase of exploration. The technique has demonstrated an ability to reduce costs by reducing drilling in the early phase of exploration.

An ongoing program of development is continuing to systematically expand the applicability of the technique to other aspects of mineral exploration. It is the intention to upgrade this manual as further relevant applications pass through the various stages of research and testing that MMI TECHNOLOGY undertakes as part of its ongoing internal research and development program.

The MMI Process is an innovative, robust, and cost effective integrated geochemical exploration package. However, it does require careful application to maximize the value from interpretation. Applied diligently, the MMI Process can deliver significant benefits from the soil sampling phase of exploration.

Should you have any queries regarding the analytical aspects of MMI Geochemistry, or require assistance with orientation surveys and interpretation, please do not hesitate to contact the members of our staff:

Mr Russell Birrell	Director
Dr Alan Mann	Director
Mr Toby Foster	Operations Manager
Mrs Sue Staltari	Technical Assistant

APPENDICES

Appendix I	Response Ratio and Cost Comparison Worksheet
-------------------	--

1.0 INTRODUCTION

'Mobile Metal Ions' is a term used to describe ions which have moved in the weathering zone and that are only weakly or loosely attached to surface soil particles. It is a widely held belief that these Mobile Metal Ions are transported from deeply-buried ore bodies to the surface. Studies from Australia and overseas have shown that such Mobile Metal Ions are useful in locating buried mineralization. Mobile Metal Ions are generally at very low concentrations in the soil. To successfully interpret these weak signals, a series of very carefully quality-controlled steps have been developed that, when put together, constitute an integrated package '**The MMI Process**'.

The steps, which are necessary to ensure the successful application of Mobile Metal Ion geochemistry for mineral exploration, include:

- A field, commodity and exploration situation appropriate for application of MMI geochemistry;
- An understanding of landform and regolith relationships;
- Application of appropriate specialized digestions;
- Access to advanced ICP-MS analytical equipment/techniques; and
- Correct interpretation of the partial extraction analytical data.

Orientation surveys are recommended, where possible, to develop a level of confidence for any particular prospect or project area.

Currently, the optimum application for MMI geochemistry is to define specific mineralization targets for detailed drilling, making broad reconnaissance RAB programmes less important. In this scenario, the assumption is that a number of target areas have been defined and MMI is used to prioritize and more accurately define targets for RC drill programmes.

Developmental work has allowed extension of the technique to a regional application, and also a target definition role.

2.0 BACKGROUND INFORMATION

The key attributes of Mobile Metal Ion surface soil geochemical anomalies include:

- Constrained, precise anomalies, vertically above oxidizing mineralization and occasionally at up-dip projection positions on the surface;
- Commodity elements respond reducing the need for pathfinders;
- The anomalies can precisely target mineralization at significant depths;
- The incidence of false anomalies is very low in comparison to conventional geochemistry;
- Surface soil anomalies are repeatable and persist over time; and
- Anomalies have a better signal to noise ratio related to mineralization in a much wider range of regolith units when compared with conventional techniques.

The Mobile Metal Ion geochemical technique has been developed since 1990 and resulted from an initial series of 13 case studies where the attributes summarized above were first observed. After this initial field testing in Australia and off-shore, a larger scale research and development initiative was instigated culminating in the establishment of The Geochemistry Research Centre at Technology Park in Perth. In an effort to understand and effectively apply MMI geochemistry to mineral exploration, its first project, The Mechanism of Formation of Mobile Metal Ion Anomalies, was supported by 11 mining companies, WAMTECH and the Western Australian State Government. As a result of the success of the first project a second project titled, Geochemical Anomalies – Their Dynamic Nature and Interpretation, began in late 1995 and ran for a period of two years. Wamtech is still actively involved with the Geochemistry Research Centre today.

It is important to realize that the MMI approach to geochemical exploration is significantly different to that used in conventional surveys. The principal aim of the process is to remove the smallest amount of metal ions from the exterior of soil particles whilst leaving the substrate unaffected. This is the essential difference between MMI and other partial digestion techniques that specifically attack substrates, such as iron oxides and manganese oxides. This approach optimizes the use of improved analytical instrumentation with lower detection limits now available. While absolute metal concentration levels are significantly less than those from 'total digestions', the signal to noise ratios are significantly enhanced using MMI procedures.

Early case studies clearly suggested that, on an empirical basis, better contrast was achieved over a number of different styles of mineralization using MMI when compared to conventional (total) techniques. It was postulated that the very loosely-attached ions were sourced from mineralization and that input from other sources of metals, for example lateritic or lithological contributions would be minimized.

The concept of the **MMI Process** has been introduced to reinforce the requirement that the method is not simply an analytical technique. It is a series of integrated steps that, when combined correctly and intelligently, is proving to be a powerful addition to the existing exploration geochemistry techniques.

3.0 APPROPRIATE LANDFORM AND REGOLITH SITUATIONS

Mobile Metal Ion geochemistry has proved successful in a broad range of landform situations including relict, erosional, and depositional regimes. It is also proving effective in lateritic terrains by identifying primary sources of mineralization from the surface within broader conventional anomalies influenced by specific regolith units.

Surface Mobile Metal Ion geochemistry essentially responds to sources of mineralization, so that weakly-mineralized structures, like subsurface supergene mineralization blankets, are defined at a lower contrast level than the primary zones from which they are derived.

3.1 Relict and Erosional Regimes

Surface regolith units developed on relict and erosional landforms respond well to MMI geochemistry. The key advantage is a superior signal to noise ratio over mineralization. Compared to conventional geochemistry, it allows better focusing on follow-up exploration, either further surface sampling or more precise target drilling. Conventional responses are usually broader and maxima are often not directly over mineralization, particularly in deeply-weathered terrains. MMI responses are more constrained; commodity element anomalies are usually closely related to primary mineralization.

This does not automatically ensure that a commercially viable deposit is identified beneath each MMI anomaly. However, the success rate for ore-grade drill intercepts early within an exploration programme can be significantly improved.

At an operational level, MMI samples can easily be collected from the surface of these regimes in a straightforward manner as discussed in the sampling procedure section.

3.2 Depositional Regimes

Surface soils on depositional regimes need to be addressed with extra care. Case studies have shown that the MMI technique extends the range of effective surface soil geochemistry further into more complex transported regolith units, when compared to conventional geochemical techniques. Again it is the superior *signal to noise* or *anomaly to background* responses provided by MMI geochemistry that allow the technique to identify and highlight anomalous responses from mineralization while reducing the effects of spurious background levels.

Terrain with colluvial soils, where coarser components are obvious, usually respond well to the MMI technique. In terrain with extensive alluvium, particularly within larger tracts of sheetwash with intermittent flood activity, care is required with any geochemical technique. MMI anomalies in this terrain type can be of the order of 1 ppb or less. At these analytical levels, great care must be taken to ensure quality of data, and correct interpretation. No geochemistry, including MMI, is successful where very active ingress of depositional material occurs, such as aeolian dunes and active alluvial channels.

An effective *orientation study* is strongly recommended if possible to provide data before embarking on a survey.

4.0 ORIENTATION STUDIES

Although MMI geochemistry is a powerful technique, it should not be regarded as a panacea for exploration. Field inspection can be important to establish whether any major landform or regolith changes are likely to influence the MMI results. Other relevant background material that can contribute to a successful MMI survey programme and interpretation includes: geological maps, aerial photographs, geophysical data including aeromagnetic maps and any interpretation thereof, conventional geochemistry results showing broader anomalies or corridors, and styles of any known mineralization.

As with any geochemical survey, an orientation programme can provide valuable information if a suitable target can be accessed and soils collected at the surface. Prior to any orientation, it is also important for the exploration professional to define the parameters for minimum target size, especially when considering sample spacing for future exploration surveys. An important feature of MMI geochemistry is that it essentially responds to oxidizing primary mineralization. Weakly-mineralized structures may not respond clearly or distinctly to an MMI programme so an orientation should preferably test a target considered significant.

A sampling interval appropriate to the dimensions of the target and host geology is recommended for orientation surveys. Generally, a 25 – 50 metre interval sample spacing along lines is sufficient. However, in the final stages of NiS exploration, 10 metre spacing is used.

To obtain the further benefit from the analytical data generated using commercial MMI analyses, response ratios (discussed below) can be calculated. Background samples provide the necessary data to allow meaningful response ratios to be calculated and therefore orientation sampling **must** include soils collected off the known mineralization.

5.0 SAMPLE DENSITY AND GRID ORIENTATION

Density of sampling is largely influenced by the type and style of mineralization being sought. Narrow, higher grade styles require a maximum of 50-m sample intervals along lines spaced according to the required strike length of mineralization considered as an economic target within the specific project area. If the minimum strike length is 200 m, then the maximum line spacing should be 200 m. This is assuming that the target mineralization is likely to produce a geochemical halo, giving rise to an anomaly that may extend further than 200 m (for example along strike of a mineralized structure). However, it is recommended that the line spacing be equal or less than the target mineralization length. Generally for gold targets a sample spacing of 100 m x 50 m will allow a focused drill programme to commence, eliminating blanket RAB drilling.

Larger sedimentary styles (for example Mississippi Valley style) can have expanded sample patterns. However, in these cases it is vital that background is also sampled. Very specific targets, for example massive nickel sulphides along basal contacts, have in the past required 25 m x 25 m, or even 20 m x 10m spacing to allow detailed anomaly definition prior to the first phase of drilling. This pattern density may represent the second or third infill phase of MMI sampling after an initial broader-spaced programme to identify contacts, or complementary with geophysical targets.

One important aspect of incorporating MMI geochemistry into an exploration programme is that it can substantially reduce drilling costs (see Figure 1). If anomalies remain strong along significant strike lengths and more precise targets are desired, it is still more cost effective to undertake infill surface sampling within the anomalous trend rather than to blanket drill.

COST COMPARISON: CONVENTIONAL vs MMI

**Case Study: Discovery of the Golden Web Gold Deposit, St Francis Mining
Exploration Phase 1 - Grassroots to Pre-definition drilling**

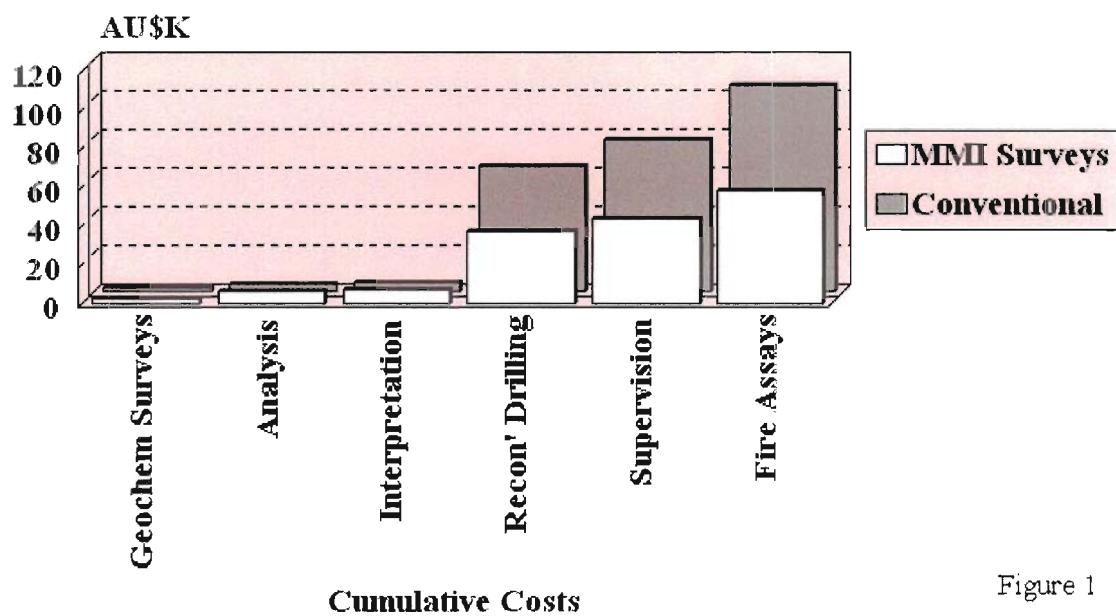

Figure 1

5.1 Sampling Grids

Pre-designated sample grids and numbers should be established prior to sampling to avoid irregular sample spacing/numbering which disrupts later data interpretation and any subsequent follow-up work. Sampling should be conducted in a methodical way, preferably starting from the lowest easting and northing and working upwards. Avoid allocating negative eastings and northings for sample co-ordinates.

For orientation, survey traverses across known targets are ideal. These traverses can be assessed independently; however, it is imperative that background samples are collected for the general area, even at the expense of maintaining a consistent spacing along the line once the mineralized zone has been covered.

6.0 SAMPLE COLLECTION

6.1 Sampling Position

Do not vary depth beneath the true soil interface, or target a specific layer/feature of a soil profile when sampling. - Extensive research has shown that element concentrations can vary markedly with a change in sampling depth. Any significant variation in sampling depth and technique can cause severe problems for interpretation. It is imperative that all samples are collected in a consistent manner. In tropical terrains, the true soil interface is the ground surface. In terrains with deep organic overburden, the true soil interface is the position where living plant matter ceases and inorganic soil material becomes evident.

In undisturbed environments samples should be collected approximately 10 to 25 cm below the true soil interface at a consistent depth. - The initial step in taking an MMI soil sample requires the surface soil layer to be scraped away eliminating loose organic matter, debris, and any possible contamination. In cases where there is an extensive organic horizon (O or Ao) at the surface, (e.g. Canada), the sample should be taken 10 to 25cm below the lower interface, i.e. into the A horizon. Before actually taking the soil sample material, equipment should be brushed to eliminate residue from previous samples and preferably flushed with the soil from the new sample site. During sample collection and handling, **no jewellery** (watches, rings, bracelets, and chains) should be worn, as this can be a major source of contamination.

Moist Samples. - Damp samples should be collected in a similar manner to soils in dry environments. Samples should not be dried in ovens or pulverised in crushers or mills. In the case of dry plastic clays, sample material can be desegregated by crushing with a mallet between disposable plastic sheets. Sieving should be avoided if there is any possibility of serious cross-contamination during sample collection via the sieve. In this case, larger rocks and twigs/leaves etc can be removed by hand.

Organic Material. - Organic material in the form of fine roots and hairs, decomposing leaf material and other fine organic debris **WILL NOT** adversely affect MMI analyses. Experimental work has shown that variability in sampling depth has a more significant impact on element responses.

Contaminated Sites. - Where there is a potential contamination problem, samples should be collected at a depth so as to avoid any contaminated material and the sampler's judgment must be relied upon. Another option available to the sampler if there is possible site contamination is to sample in the lee of a tree and/or under a thick layer of organic litter.

6.2 Equipment

- A 30-cm diameter **plastic** garden sieve or kitchen colander with minus 5-mm apertures, available from hardware and supermarkets, is ideal for sample collection;
- **Plastic** collection dish with similar diameter and a kitchen floor brush used for cleaning the sieve and dish between samples;
- A bare steel (no paint) garden spade; and
- **Plastic** snap seal bags, **do not use calico**.

6.3 Sample Specification

A 250 gram sample is collected and stored in a plastic bag (a 90 x 150-mm plastic snap seal sample bag is recommended). Once sealed in the snap seal plastic bags, samples should be placed in polyweave sample dispatch bags. Stored in this manner, samples can be carried on tray-back vehicles during summer without problems and be stored for long periods.

6.4 Sample Site

Sample sites should be undisturbed and preferably away from any major contamination: creek beds, drainage, drilling lines, pads, roads, etc. Wind borne contamination should also be eliminated during sample collection by sampling just below the surface.

MMI SOIL SAMPLING - IN SUMMARY

- **Use one laboratory wherever possible.**
- **For a particular survey, avoid submitting samples in small batches (if possible). If this cannot be avoided, calculate Response Ratios for each batch, BEFORE combining the data.**
- **Always sample consistently 10 – 25cm below the true soil interface.**

6.5 Other Assistance

MMI TECHNOLOGY has assembled a number of technical bulletins to assist users with their sampling programs. This information can be accessed via the MMI Web Page or copies can be obtained from MMI Technology or its licensed laboratories worldwide. MMI staff can be made available to visit survey sites, discuss sampling procedures, train personnel, and perform sample collection.

7.0 STANDARD REFERENCE MATERIAL CHECKS AND DUPLICATE SAMPLES

Standard Reference Material (SRM) and duplicate samples are a very important part of quality assurance and control, by identifying any human or equipment error. They also provide the required measure of confidence in the data reported by the laboratory.

One check and one duplicate sample should be inserted for every batch of 50 samples. Preferably these should be inserted within the normal sample number sequence submitted to the laboratory. MMI TECHNOLOGY can supply standard reference material at a nominal cost. Companies can also collect their own check material once values from a specific sample site are known.

Mobile Metal Ion responses in soils are consistent, repeatable, and there is no nugget effect. The ions are distributed homogeneously throughout the soil and it is possible to engineer a desired standard reference sample value by mixing samples with known responses (see Figure 2). As can be seen from this case study, the mean of the two samples that were combined in equal proportions and thoroughly mixed gave an accurate indication of the results of four sub samples.

Mobile Metal Ion Distribution

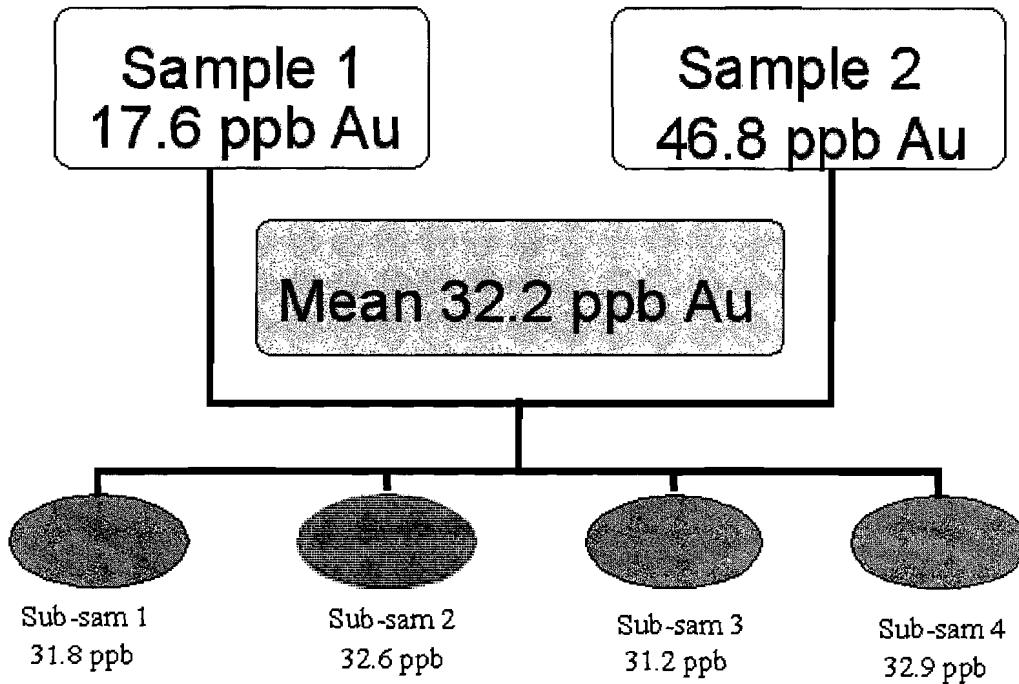

Figure 2

8.0 SAMPLE SUBMISSION

Before submitting the samples to the laboratory, samples for the survey should be collected and stored until the whole job has been completed. Only then should the samples be submitted as a single batch to a laboratory licensed by WAMTECH to undertake Mobile Metal Ion Analyses. A **Sample Submission Form** is included in Appendix II at the rear of the manual. By submitting the samples as a single batch, the samples are less prone to any slight degree of variation that may occur due to different laboratory conditions. This also allows the data to be received as a single batch reducing the chance of database corruption.

8.1 Overseas Sample Submission

Samples dispatched to laboratories overseas, depending upon local legislation, must go through various custom and quarantine procedures. Generally, laboratories must be registered as a quarantine laboratory to accept deliveries of samples from overseas for chemical analysis. This registration usually requires that the laboratory render the samples and packaging biologically sterile prior to disposal by heat treating samples and packaging. To allow efficient and quick release by Customs and Quarantine services, it is imperative that all documentation is clearly and concisely filled out. For the correct documentation and procedures contact your local Customs services and the analysing laboratory or MMI Technology, Perth, Australia. Samples arriving from overseas are usually subject to various government charges on each consignment. The laboratories will also most likely have an additional charge to cover their cost of handling and disposal of quarantine samples. For this reason the larger the sample batches or consignments, the more cost effective the analyses.

9.0 ANALYSES

Currently two commercial laboratories, ALS-CHEMEX, in Perth, Australia, and SGS in Toronto, Canada are licensed to undertake **Mobile Metal Ion Analysis**. Prior to this agreement, a detailed development programme was undertaken to ensure that the required analytical standards were being met and could be delivered on a routine, commercial basis. MMI Technology has a rigorous quality control check programme to ensure that the required laboratory standards are being maintained and the digest liquors provided to the laboratory meet the required stringent extraction criteria. Each digest liquor supplied to the laboratories is provided with an individual warranty form for that specific liquor, and to which it must conform.

The MMI Process uses leachant solutions which have been specially developed to selectively 'release' the adsorbed ions from the soil material. The aim of the selective leaching is to remove metals which are loosely bound on the surface of particles within existing soil profiles, without attacking or influencing the natural mineralization of the soil or specific substrates. Using sensitive ICPMS instrumentation, the MMI Process is able to detect Mobile Metal Ions in digest solutions at sub-parts per billion level.

Eight MMI leachants are currently available:

- MMI-A:** Cu, Pb, Zn, Cd (Base Metals)
- MMI-B:** Au, Ag, Ni, Co, Pd (Precious Metals)
- MMI-C:** Cu, Pb, Zn, Cd (Base Metals in Carbonate Environments)
- MMI-D:** Ni, Co, Pd, Nb, Cr, Mg, Rb, Y (Diamond Host Rocks)
- MMI-F:** As, Sb, Hg, Mo, Se, Fe (Pathfinders)
- MMI-G:** U, Th, Pb, Ta, W, Sn (Pegmatites)
- MMI-L:** Au, Ag, Ni, Co, Pd (Precious Metals in Super Absorbent or Highly Saline Environments)
- MMI-M:** All of the above elements + rare earths (Multi Element Extraction)

[Detection limits for each element and leach and costs are available from the MMI licensed laboratory]

9.1 Quality Control

As with any geochemical survey, it is important to maintain a check sample programme independent from that undertaken by the laboratory. One standard reference material and one duplicate sample should be inserted within each sequence of 50 samples to monitor precision and accuracy. It is preferred that the QC samples be inserted as part of the numbering sequence but not essential. If MMI TECHNOLOGY is to be actively involved in the programme as consultants, standard reference material and duplicate sample will be monitored and reported upon. The precision and accuracy of MMI analyses is typically very high.

10.0 DATA HANDLING

Each individual laboratory has its own method of data reporting, most will usually supply the results via email. The dispatch and retrieval of results is the responsibility of the laboratory and client. Once the results have been received, care should be taken not to corrupt the original data and to safeguard against its loss. As the samples should have been submitted as a single batch, the results should also be available as a single database. This helps avoid possible data corruption by reducing data transfer and manipulation.

10.1 MMI Response Ratios

MMI interpretation of individual elements can be done on raw (ppb) data. To facilitate multi-element interpretation of MMI analytical data, it is recommended that for each element, a background for the data is calculated, using (say) the lowest quartile of the data. Then a peak to background ratio (**response ratio**) is calculated for each element for each sample. A simple work sheet on MMI Response Ratios is included in Appendix I.

Response ratios provide a number of benefits for interpretation:

- Reduce the effects of dissolution variables during extraction, for example time and temperature;
- Allow the splicing of different data batches or data from varying regolith situations;
- Reduce the effects of sampling in different regolith units; and
- Facilitate multi-element data presentations for interpretation.

Before presenting MMI data in any graphical form, individual element response ratios are calculated for each sample. The concept of response ratios is simple: it involves determining a background value for each element in a survey area and ratioing all the data to that background. In more detail:

Determining the Background

- Select an element, for example Au, and determine the lowest 25% of the data for all the samples analysed in the survey area.
- Any values less than the detection limit need to be included and a value half of the detection limit should be substituted as an estimate value (based on scientific reports). For example, if Au has a detection limit of 0.01 ppb, any sample that analysed below this should be given a substituted value of 0.005 ppb.
- After determining the lowest quartile (25%) of the data, the average of these values is then calculated. This is the BACKGROUND value for that element within the specific dataset of a survey area.

Calculating MMI Response Ratios

- Response ratios are calculated by dividing each sample value by the predetermined background value for that element. The numbers are then rounded to give whole numbers greater than or equal to one (1).
- A sample with a response ratio of 2, or less, is considered low and is a background sample. Samples with response ratios greater than 5 could be considered significant depending upon the regolith/landform characteristics of the area and the sample spacing used for the survey. *Note however, that due to the greater contrast inherent in the MMI technique, response ratios in general need to be greater than 2-5 times background before being considered “anomalous”.* If composite sampling has been employed then response ratios greater than 5 may be highly significant. Obviously, this may change depending upon the overall distribution and magnitude of response ratios in an area. For example, some areas may have anomalous Au values at 10 (RR) whereas for another area the anomalous Au values may be those samples with a response ratio greater than 20.

Additional advantages of using response ratios are:

1. The effective application of MMI Response ratios relies upon correct determination of the background for the survey area. It is important that the survey area covers sufficient ground and has not just been conducted over a mineralized sequence. Correct determination of the background and ratioing of all the data to that value helps distinguish between those samples which are anomalous and those which are not. With MMI we are not looking at the absolute value of an element (for example Au) in a sample as it is a partial extraction technique. Instead, we are interested in the relative difference between background samples and those which are anomalous and which may overlie mineralization.
2. Response Ratio data is in a uniform format, allowing individual elements to be compared directly for coincident or zoned anomalies that can be easily identified using stacked bar charts.

-
3. Response ratios are also valuable for dealing with multiple batch analysis where slight batch variations can occur during extraction. In some cases response ratios have been useful where highly-transported soils exist in conjunction with relict and erosional regimes by enabling the samples to be treated in separate datasets according to their regolith type.

The method of calculating response ratios for MMI data is certainly not a new one in geochemistry, although many people will argue it is an attempt to enhance the data. This is not the case as response ratios are merely a relative comparison of signal to background. It is also important to remember that all data from a laboratory are going to be relative; that is, relative to the standard used in the laboratory.

After response ratios have been calculated, the data can easily be presented in various ways to show required features and indicate trends. There is no set formula for defining the significance of any particular set of response ratio data. A number of factors will influence the final results. Orientation sampling can provide some assistance; however, like most exploration techniques experience with the technique is invaluable.

11.0 MMI IMAGING and INTERPRETATION SERVICES

As noted earlier, MMI provides sharp, high contrast anomalies compared to conventional or total digestion geochemistry. This can pose problems for the unwary, or the geologist trained only in interpretation of conventional geochemistry. To assist MMI users with interpretation and presentation of MMI data, MMI Technology provides a range of Imaging and Interpretation services to suit specific client needs. The services available range from database management and calculation of response ratios, through to in-depth imaging and interpretation reports, and also a consulting service. A table of available services is shown in the table below.

MMI Technology
Schedule of Services and Prices - May, 2004

SERVICE 1			
Data Base Management			
Data base construction incorporating analytical QA/QC, analyses, coordinates and response ratios.			
Stacked Bar Charts		Coloured Images/Maps	
Stacked bar charts showing specific element associations at sample sites along a line or traverse.		Coloured contour images of element responses.	
<i>Price Schedule</i>		<i>Price Schedule</i>	
1 Line	US\$ 230	<100 Samples	US\$ 540
2-10 lines	US\$ 450	100-300 Samples	US\$ 660
>10 lines	US\$ 690	>300 Samples	US\$ 770
Stacked Bars + Coloured Images			
<i>Price Schedule</i>			
<100 Samples		US\$ 720	
100-300 Samples		US\$ 1050	
>300 Samples		US\$ 1400	

SERVICE 2**Data Interpretation**

Includes database construction incorporating analytical QA/QC, analyses, coordinates and response ratios, stacked bars and coloured images.

<u>Quick Look</u>	<u>Detailed Review</u>
Brief review and comment on element responses as shown on stacked bar charts and coloured maps.	A full report including database, images, interpretation and recommendations.
<u>Price Schedule</u>	
<100 Samples	US\$ 1000
100-300 Samples	US\$ 1150
>300 Samples	US\$ 1250
<100 Samples	US\$ 2880
100-300 Samples	US\$ 3080
>300 Samples	US\$ 3500

SERVICE 3**Consulting**

Consulting service including workshops, seminars, sample programme design, sampling instruction etc.

Principal Consultant - US\$ 80/hr
Senior Technical Officer - US\$ 50/hr

MMI Technology is also able to provide a soil sampling service. For this, and all of the above services, please contact MMI Technology for a quote to clarify any costs involved.

Services 1 and 2 are available by email, enabling a very quick turn around time for interpretation. For more information and to obtain a quote on any of the service packages, please contact MMI TECHNOLOGY at info@mmigeochem.com or visit our web site at <http://www.mmigeochem.com>.

By drawing on its extensive experience, MMI Technology is able to provide clients with precise, in-depth interpretations and recommendations from MMI data. MMI Technology can generate stunning and accurate images from MMI data. Images such as Stack Bar Charts and Coloured Contour Images (see examples in Figures 3 and 4 below) allow quick, easy and accurate interpretation so you know exactly what your MMI data is telling you.

Stacked Bar Chart of MMI Response Ratios For Base Metals

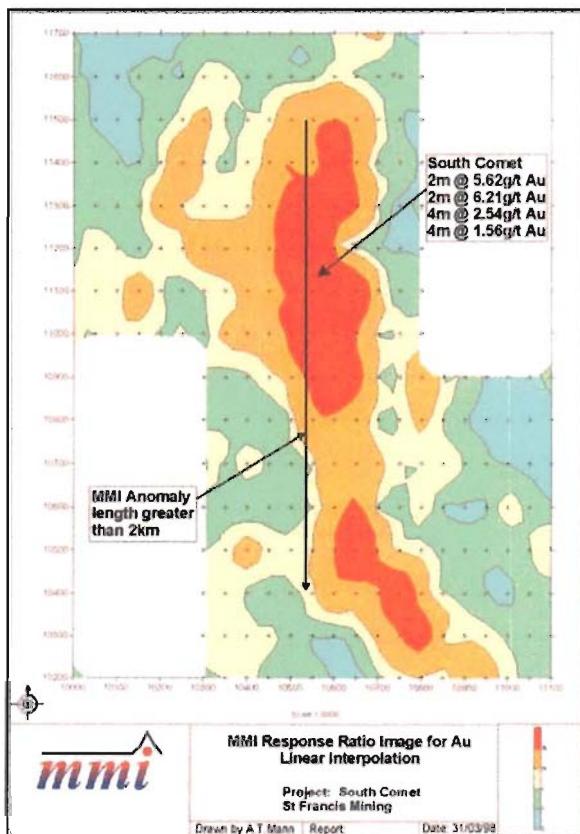

Figure 4

12.0 CASE STUDIES

MMI geochemistry has been used extensively world wide for over 10 years, generating a multitude of case studies. A selection of these case studies has been made available for publication by the participating companies. The case studies have been presented on our MMI Web Site: <http://www.mmigeochem.com> and can be downloaded and printed from the web site.

13.0 APPLICATIONS

To date, the MMI technique has been successfully applied in a number of different situations with varying commodities (including gold, base metals, nickel, and diamonds), mineralization styles, geological settings, depth of burial, and climatic regimes ranging from arid/semi-arid through to wet and both tropical and temperate. It has been successfully tested and applied on all continents in the world (barring Antarctica).

13.1 Target Drilling

The initial development of the MMI Process primarily focused on more accurate target drilling for a range of commodities in the widest possible spread of landform and regolith situations, mineralization styles, and settings. Consequently, sample spacing has been kept tight to provide the necessary data density over target areas for interpretation, thereby allowing resolution of the anomaly to define specific targets for RC drilling.

If applied in an integrated and systematic manner, MMI geochemistry can significantly improve the cost effectiveness of exploration programmes. Currently it has been used to eliminate first pass reconnaissance drilling phases and allows the programme to proceed directly to a target drilling phase. A cost comparison exercise is included in Appendix I, and a case study presenting actual exploration costs for St. Francis Mining to discover the Golden Web deposit is summarized in Figure 5.

COST COMPARISON: CONVENTIONAL vs MMI

Case Study: Discovery of the Golden Web Gold Deposit, St Francis Mining Exploration Phase 1 - Grassroots to Pre-definition drilling

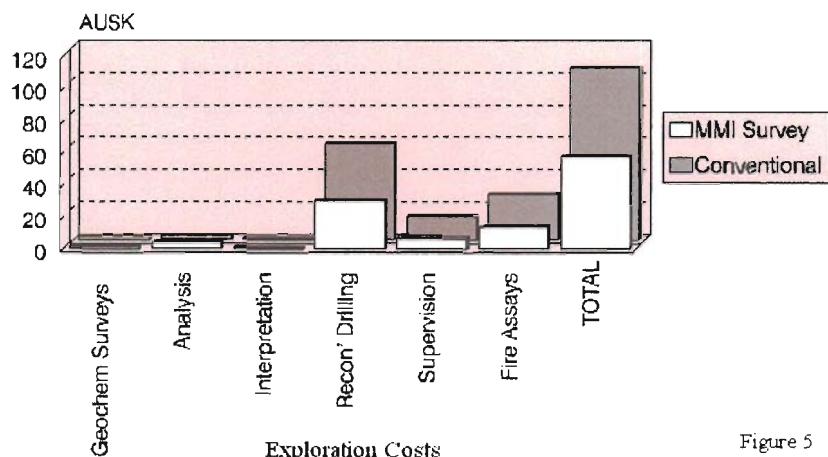

Figure 5

For target drilling the maximum sample density should be 50 m x 50 m. In situations where the target is steeply dipping, narrow, possibly with a restricted strike but significant depth extension, for example nickel sulphide lenses, then 25 m x 25 m sampling density, or even 20 m x 10 m, may need to be employed.

13.2 Definition of Mineralization Trends

In many economic ore deposits, mineralization is zoned. This is often as a consequence of the temperature and pressure variations during ore emplacement. High resolution geochemistry such as MMI can often provide sufficient spatial resolution for zoning to be seen from surface. Two examples are shown below.

The San Jorge copper-gold deposit is at the southern end of a north-south trend of various hydrothermal deposits that outcrop for over 300 km in the Uspallata Valley and its environs (Argentina). The MMI geochemistry for section 8650E, superimposed upon the known geology and sub-surface mineralisation, Figure 3, shows a number of interesting features. Firstly, there is a zonation pattern across the deposit, with outlying anomalies of Zn and Cd giving way to anomalous Cu, Au, and Ag over the primary and enriched zones of the deposit. Secondly, whilst Cu is present in considerable concentrations and reports very strongly in the MMI geochemistry, Au and Ag also report with very strong MMI response ratios over the mineralisation, considering the tenor of the Au mineralisation (average 0.2ppm). Thirdly, given the varying depth of the gravel cover, the MMI geochemistry has provided a sharp and accurate surface outline of the sub-surface mineralisation, with response ratios for Cu of over 100 times background, and Au and Ag response ratios of over 50 times background. The full case study can be viewed at <http://www.mmigeochem.com>.

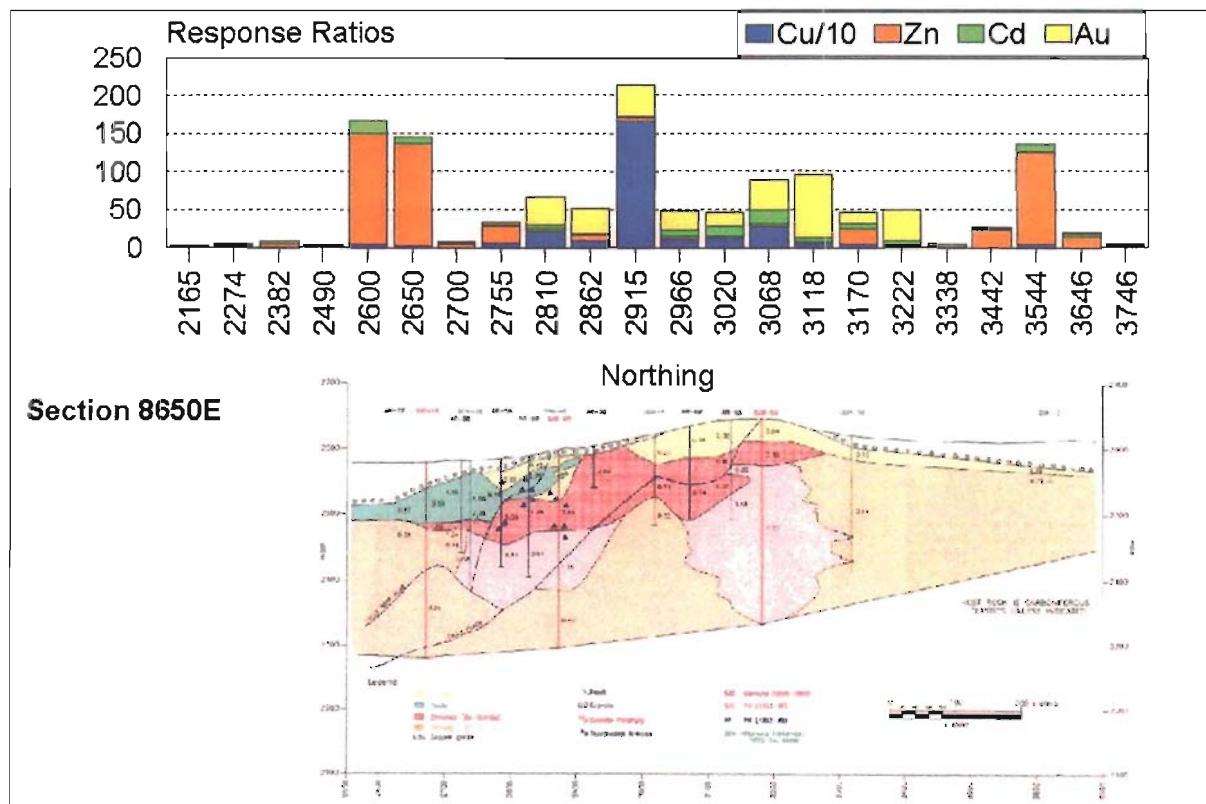

Figure 6. MMI response ratios plotted above cross sectional geology of San Jorge project, Mendoza.

The rare earth elements at Nepean, Coolgardie, Western Australia, show an interesting pattern, with a central “low” where the NiS expresses itself with very high Ni and Pd in the sample at 1000E, flanked by sharp and very high values in immediately adjacent samples. Samples more than 100m from the deposit show close to background values for these light rare earths. A possible reason can be explained by reference to the cross section below in Figure 7.

Hill (2001) has pointed out that fresh substrate rock samples commonly show high values for the light rare earth elements whereas primitive komatiites do not. The nickel sulphide bodies (after thermal erosion and mixing) commonly also have a rare earth signature. It is therefore possible to discriminate barren and potentially fertile (and therefore prospective) komatiites. It is believed that the soil samples in the traverse at 4550N (at 25m spacings) are accurately reflecting the geochemical signature of the mine sequence.

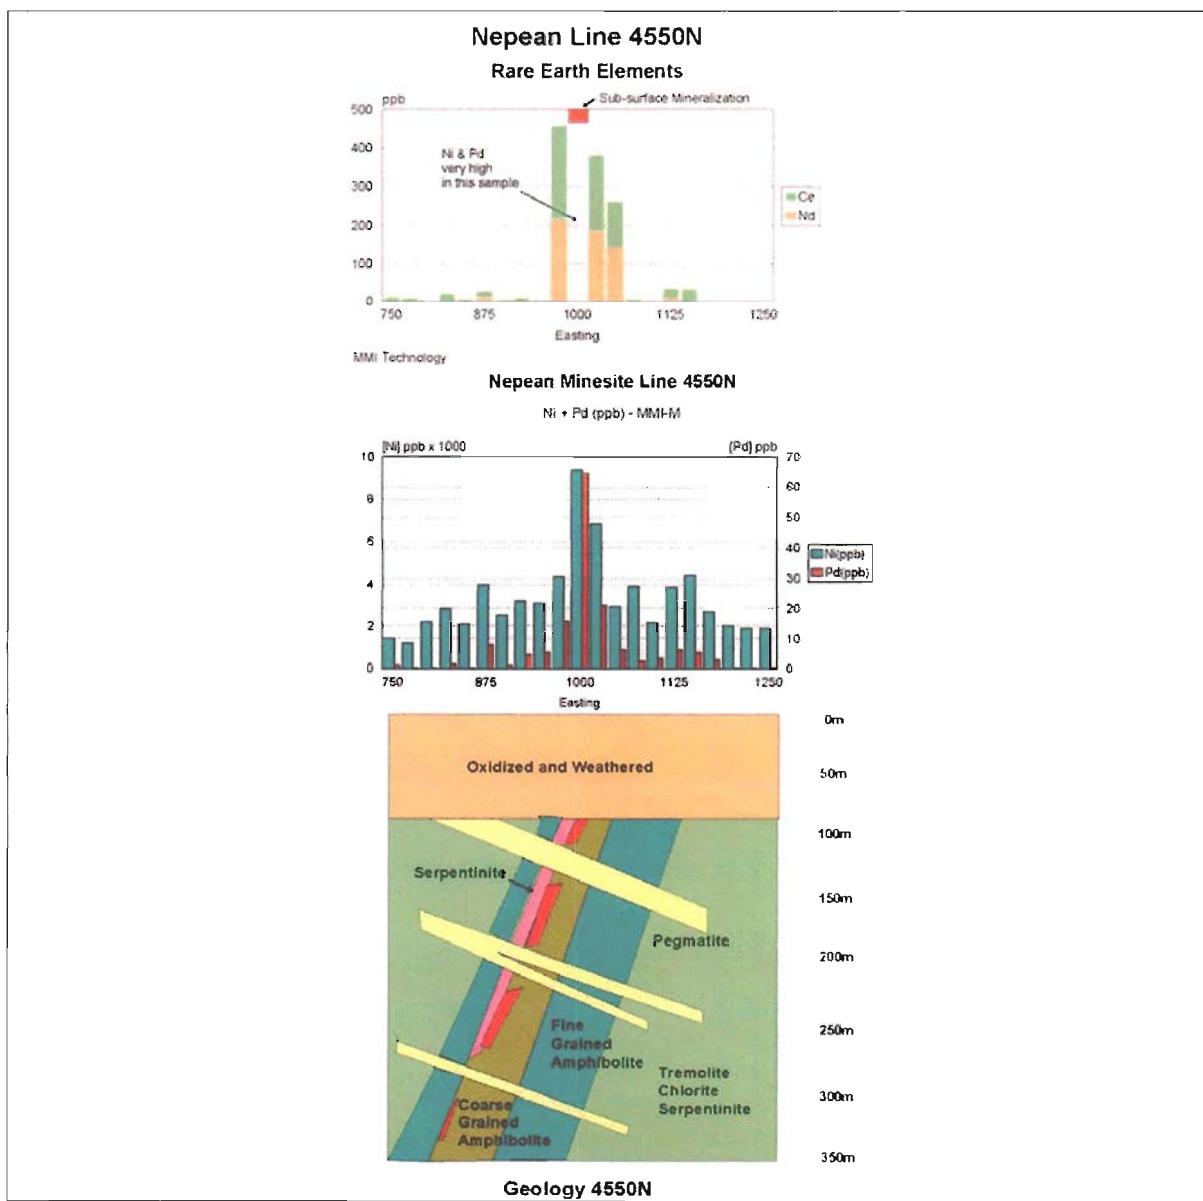

Figure 7. Rare earth elements Ce and Nd enveloping high Ni and Pd, with underlying geology, at Nepean nickel deposit, Coolgardie.

13.3 Future Developments

MMI Technology is continuing its own research and field testing to determine the practicalities and cost effectiveness for the application of MMI techniques to:

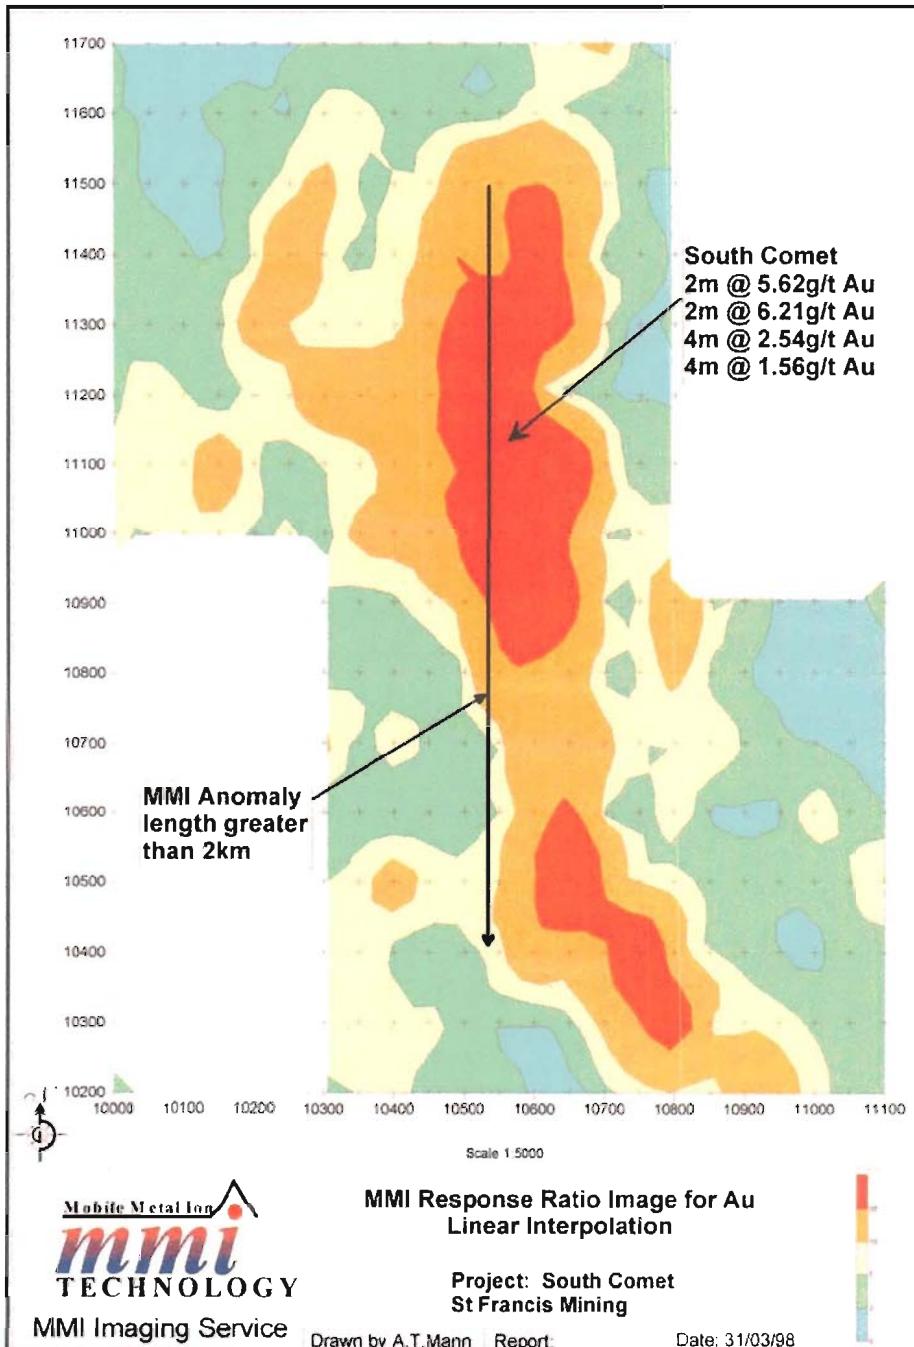

- a) Further develop the technique for definition of distinct mineralization trends within chalcophile corridors at a regional scale;
- b) Identify geochemical target zones, anomalies and trends at a prospect scale;
- c) Extend the effectiveness into those regolith terrains that are still problematical;
- d) Interpret subtle down-hole geochemical responses within deeply-weathered profiles to target deeper primary mineralization; and
- e) Identify buried, broad scale alteration haloes around large mineralization settings.

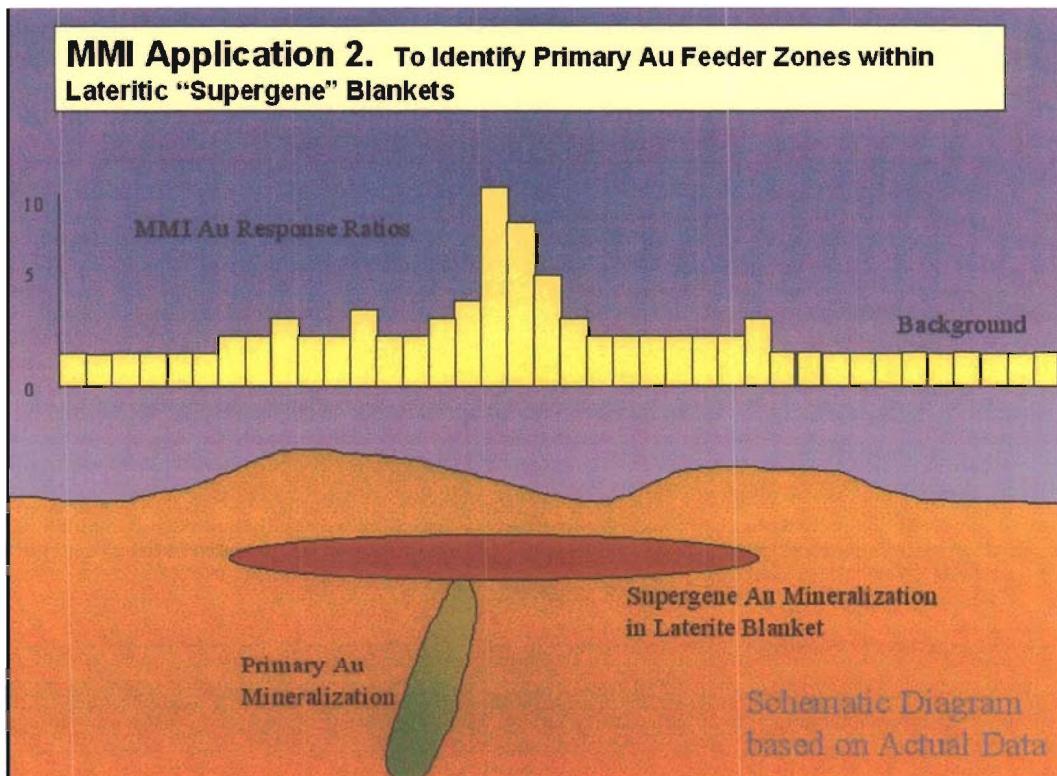

13.4 Specific Applications

Following is a list of specific MMI applications. Discrete diagrams are included for each of the applications.

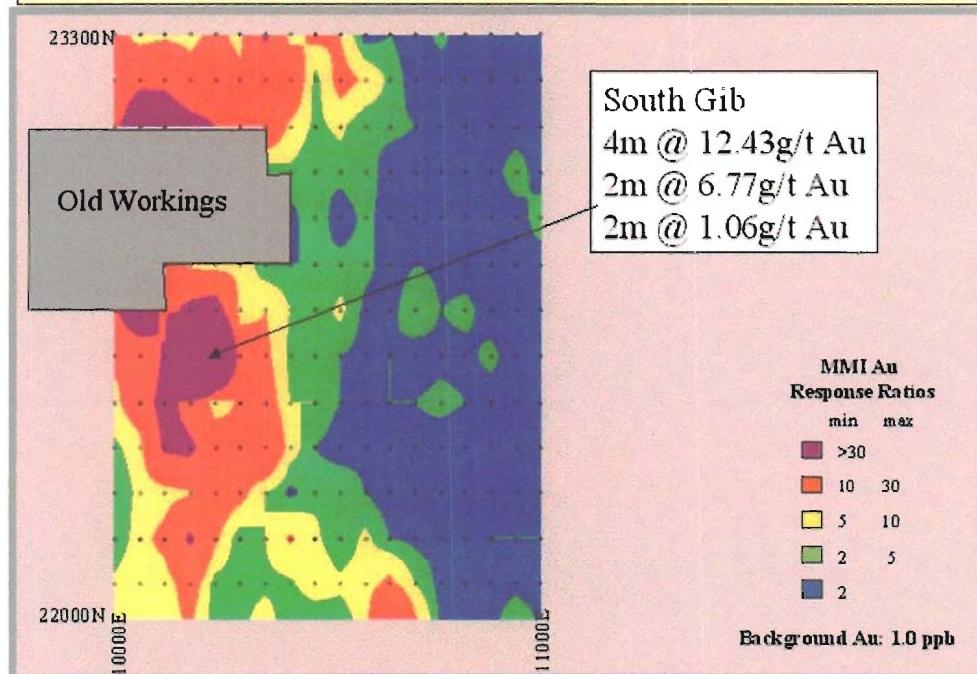

1. To provide sharp geochemistry for accurate target drilling of Au, Ni, and base metal deposits.
2. To identify primary Au feeder zones within lateritic 'supergene' blankets.
3. To accurately trace on surface, the strike extensions of known mineralized ore zones.
4. To identify genuine surface anomalies from displaced (false) anomalies in residual and erosional laterite profiles.
5. To identify ultramafic units, channel flow rocks, and mineralized basal contacts in Ni exploration.
6. To identify the surface projection position of deeply-buried base metal deposits.
7. To provide enhanced signal to noise geochemistry capabilities in depositional regimes.
8. To identify metal zonation, for example in porphyry systems.
9. Delineating mineralization in areas of strong anomalousism.
10. To provide multi-element geochemistry in regional and semi regional exploration programmes.

MMI Application 1. To Provide Sharp Geochemistry for Accurate Target Drilling of Au, Ni, and Base Metals Deposits.

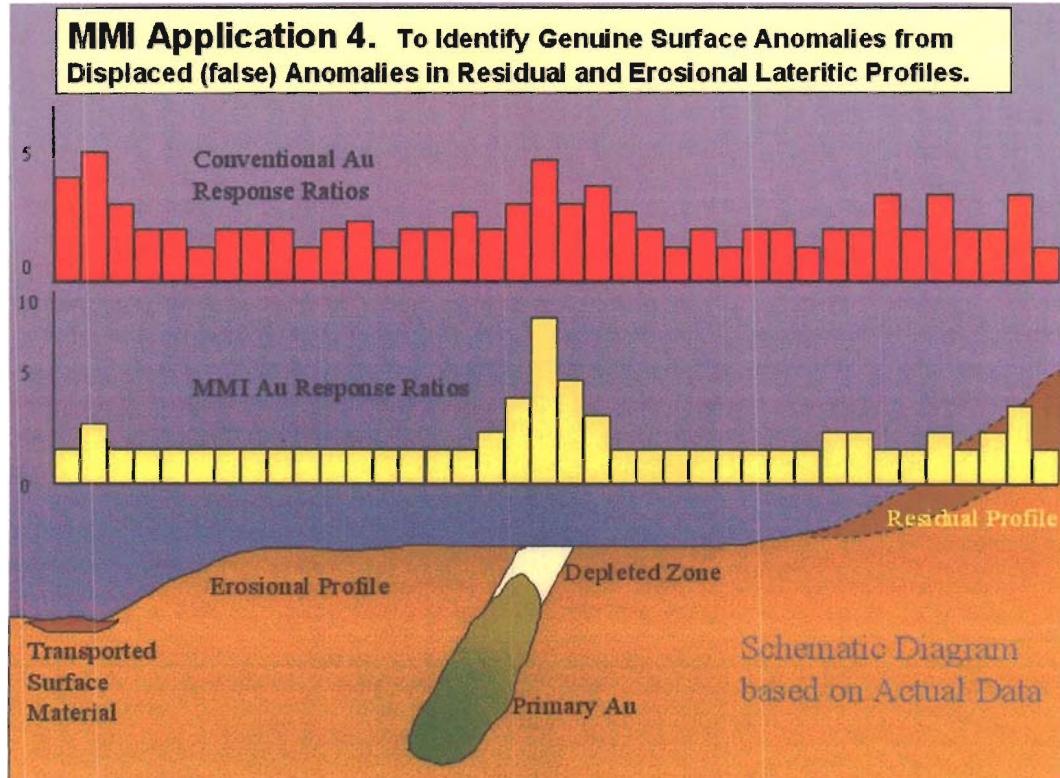

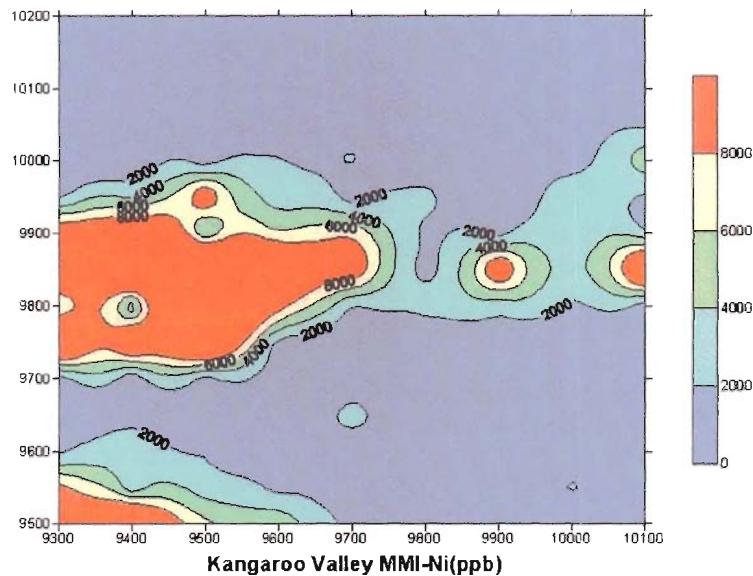

MMI Application 3. To Accurately Trace on Surface, the Strike Extensions of Known Mineralized Ore Zones

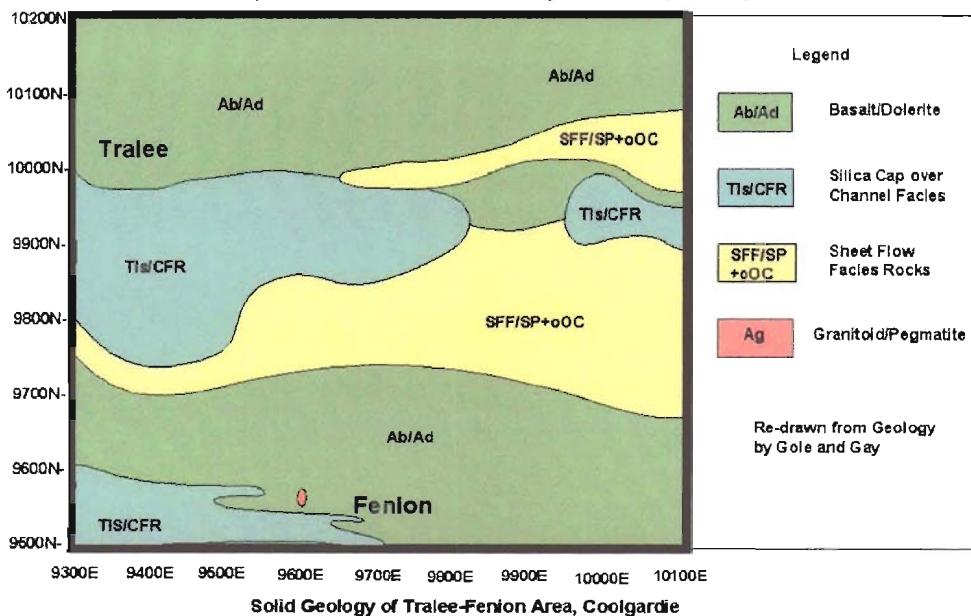

MMI Application 4. To Identify Genuine Surface Anomalies from Displaced (false) Anomalies in Residual and Erosional Lateritic Profiles.

MMI Application 5. To Identify Ultramafic Units, Channel Flow Rocks, and Mineralized Basal Contacts in Ni Exploration

MMI-B analysis of Ni in soils from Kangaroo Valley, Coolgardie, W.A.

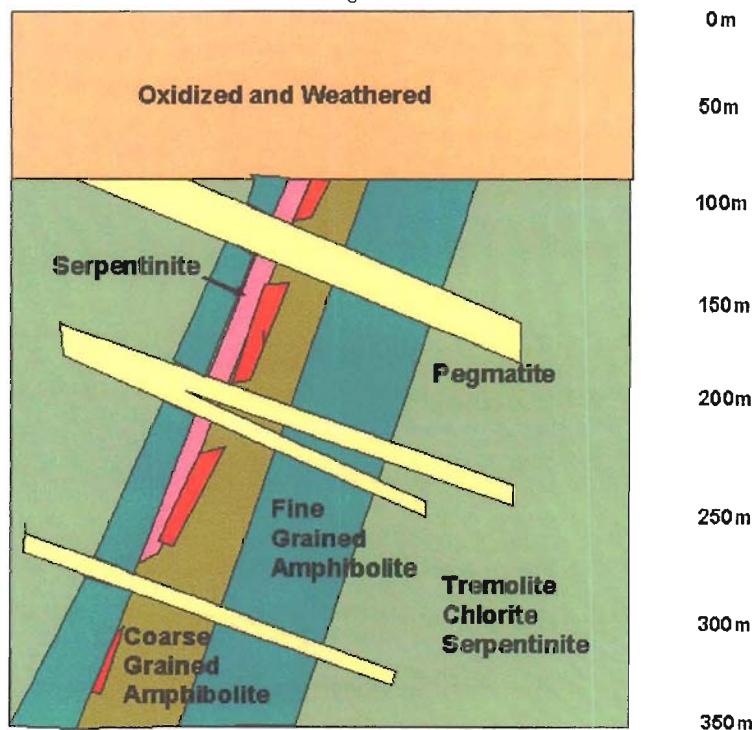

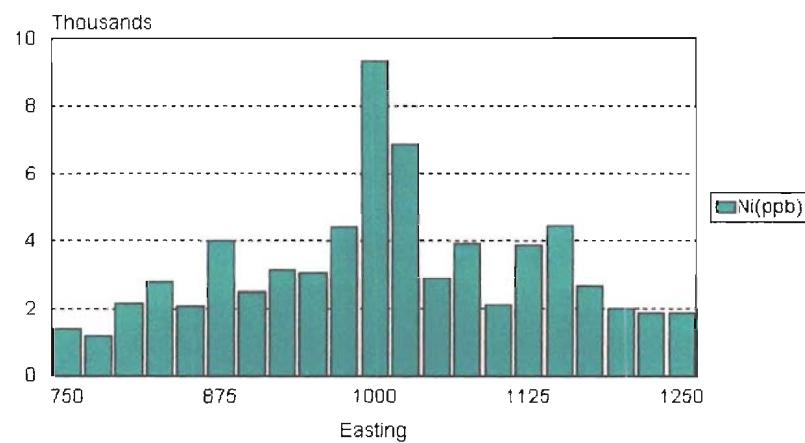

Geology of the Kangaroo Valley area, after Gole and Gay, 1995.

MMI Application 6. To Identify the Surface Projection Position of Deeply-Buried Base Metal Deposits.

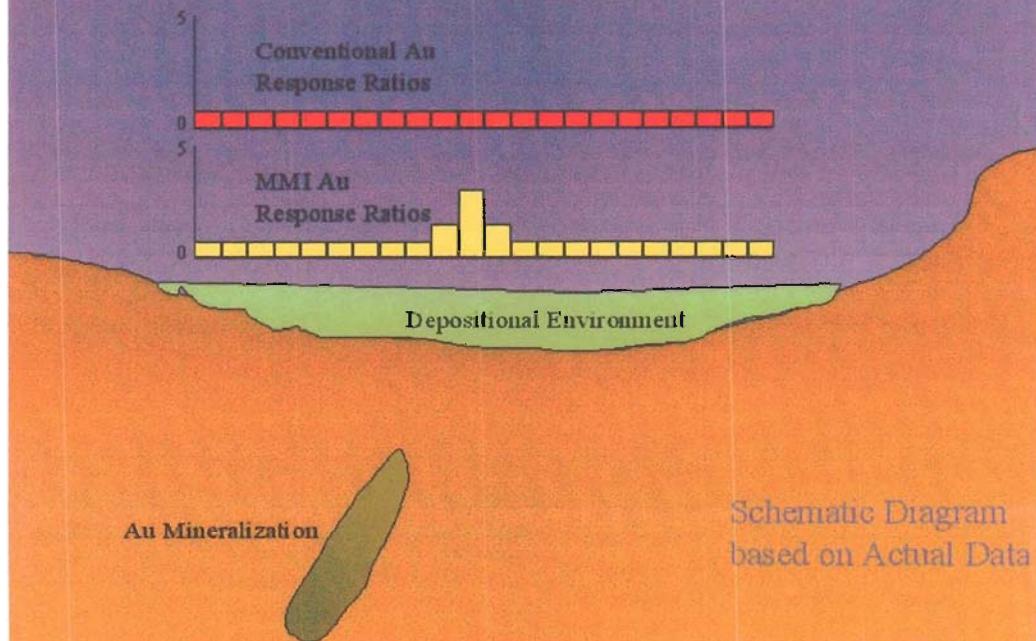

Nepean Minesite Line 4550N

Ni(ppb)- MMI-M

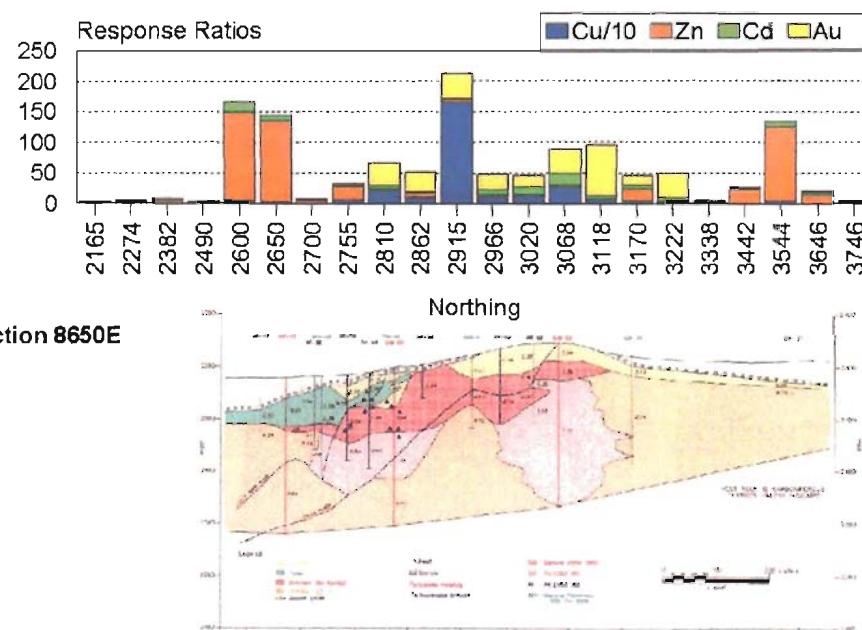

Geology 4550N

**MMI Application 7. To Provide Enhanced Signal to Noise
Geochemistry Capabilities in Depositional Regimes**

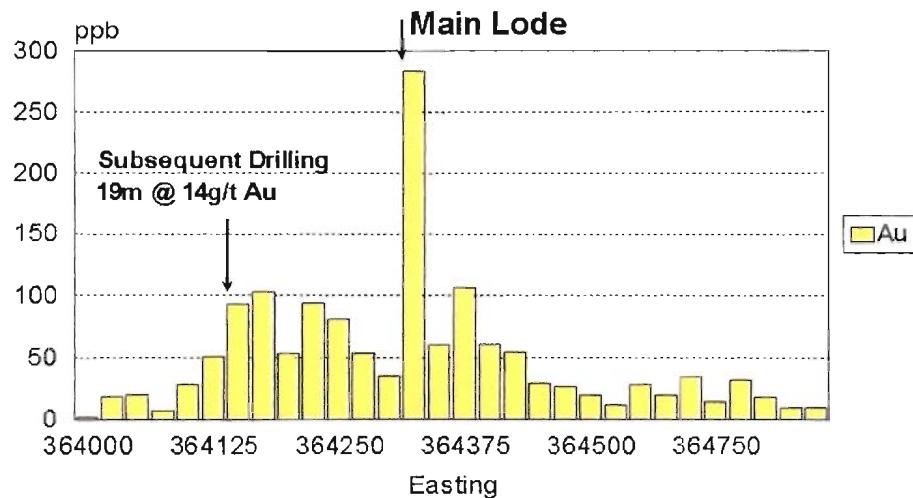

MMI Application 8. To Identify Metal Zonation, for example in Porphyry Systems.

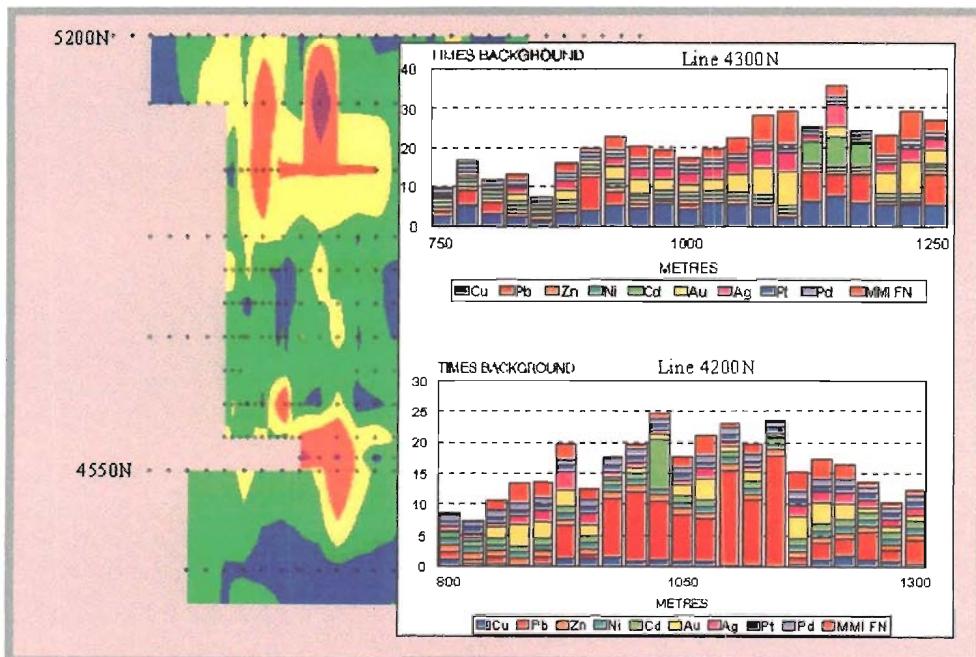

MMI Application 9. To delineate mineralization in areas of strong anomalous.

The Mount

MMI Orientation Line 6510800N

MMI Application 10. To Provide Multi-Element Geochemistry in Regional and Semi Regional Exploration Programmes

MMI RESPONSE RATIO AND COST COMPARISON WORKSHEET

MMI RESPONSE RATIO AND COST COMPARISON WORKSHEET

Why Use Partial Digestion involving Mobil Metal Ions?

To illustrate the use of partial digestions and Mobile Metal Ions we shall examine real data from a case from Central Queensland. This data came from an area where both conventional and partial digestion chemistry work, and both can provide us with figures which we can compare.

Sample	Metres (E)	Cu (Total) ppb	RR (Total)	Cu (Partial) ppb	RR (Partial)
CQ1	0	4200		100	
CQ2	25	3800		120	
CQ3	50	7000		100	
CQ4	75	17000		2500	
CQ5	100	9000		200	
CQ6	125	6000		150	
CQ7	150	5100		100	
CQ8	175	5000		150	

1. Calculate for both the conventional and the partial data sets for Cu, a background based on the lowest quartile (25%), i.e. average the lowest two values from each set.

Conventional B/G = Partial B/G =

2. Now calculate the MMI Response Ratio (RR) for each sample, by dividing each value by the background, for both data sets. Fill in the response ration data in the table above.
3. Now plot on the graph below, the signal to background (i.e. response ratio) for each sample, from each of the techniques.

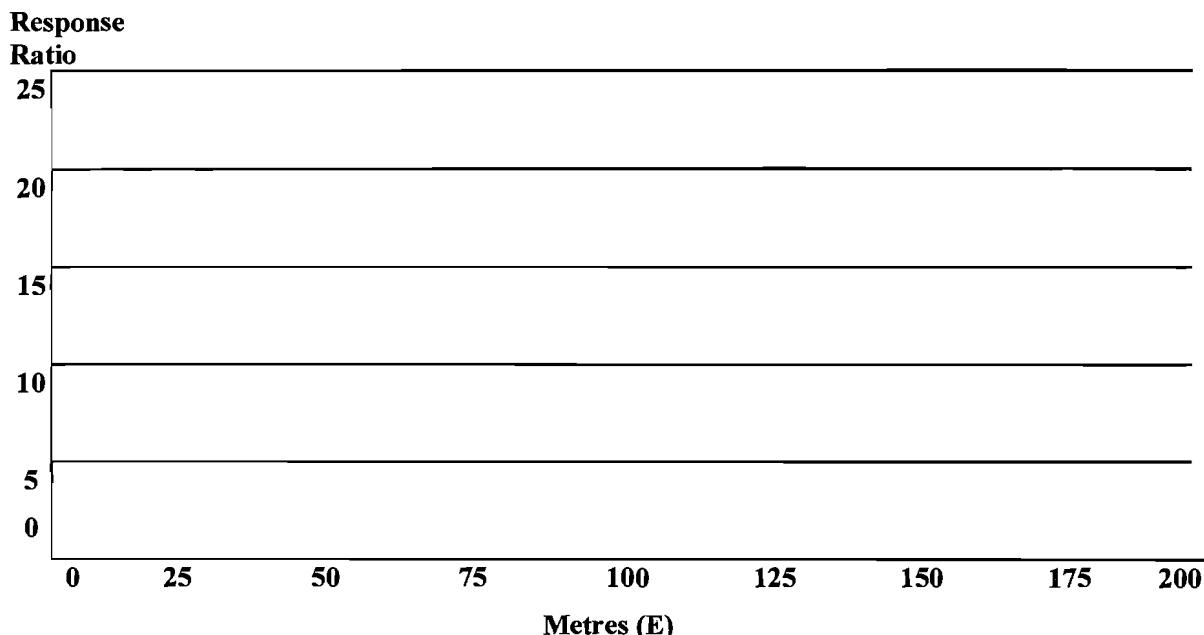

Figure 1. MMI Response Ratios for Total and Partial Digestion from a case study.

Using the MMI partial digestion, we have extracted less than 2 % of the total metal from most of the samples (note a higher percentage from the anomalous sample). By so doing we have increased the signal to noise ratio considerably. We have preferentially used unbound metal in doing this.

There are a number of possible situations where the increased signal to noise ratio of the partial geochemical anomaly may be of advantage:

1. Where the amount of transported material in take (colluvial) soil would swamp a conventional geochemical signal, but not one from partial digestion.
2. Where the depth of the mineralization is so great that the bleed signal of metal is very weak.
3. Where the amount of weathering in the profile has led to a very low metal signal in the surface soil.

There is another situation, where the increased width resolution 'the sharpness' of the partial geochemistry signal can be of great value. It relates to being able to directly target-drill from a geochemical anomaly. The present example gives some kind of illustration of this. The conventional geochemical signal has shoulders which give the anomaly a width of approximately 100 m (four samples > or = 1.5 times RR). As a second exercise we can approximately cost compare the Total Exploration Cost to the end of first round drilling of this target by these two scenarios. Use your own estimates of costs to complete the following table, assuming first round drilling would be at 25 m spacings to 50 m:

Item	MMI Geochemistry	Cost	Conventional Geochemistry	Cost
Geochemical Sampling	0.1 day @ \$	\$	0.1 day @ \$	\$
Analysis (assume a total of 80 samples)	80 samples @ \$	\$	80 samples @ \$	\$
Geochemical Interpretation	1 day @ \$	\$	0.5 day @ \$	\$
Gridding Costs	0.2 day @ \$	\$	0.2 day @ \$	\$
Drilling	100 metres @ \$	\$	200 metres @ \$	\$
Drill Supervision by Geologist	1 day @ \$	\$	2 days @ \$	\$
Downhole Samples	100 samples @ \$	\$	200 samples @ \$	\$
Other	\$	\$	\$	\$
Total	\$	\$	\$	\$

DISCUSSION.....3

APPENDIX 1 - SGS-XRAL CERTIFICATES

DISCUSSION

MMI Soil Geochemistry was completed on several areas for a test of the analysis' application to the exploration of the Sidace Lake Property, a property which is covered in large part by the Trout Lake Moraine.

Results of MMI A (Base Metal) MMI B (Au) and MMI F (Porphyry) show varied responses, with some variability due to differences in overburden thickness and drill cutting contamination.

Elevated levels of Barium, Mercury, Arsenic and Antimony are found in the preliminary ICP results for The Sidace Lake Property (report in progress) and MMI responses for these elements appear only where drill cutting are on surface, and not along the predicted horizon. Geological interpretation is also rapidly changing in this area due to ongoing drilling, and the core of the Barium, Mercury, Arsenic and Antimony anomaly in bedrock be better defined and a new MMI M (multi – element) survey over the same areas as the MMI A, B, and F surveys to validate the initial survey.

It is not believed that sample media or sampling depth is an issue with the reported MMI survey.

It is believed that recent drill cutting have contaminated some samples.

The density of samples may be insufficient to get any real background data for a property as large as the Sidace Lake Property, and a new reconnaissance survey is recommended using MMI M over the newly discovered mineral horizon on the west shore of Upper Duck Lake trending westerly to North of Anderson Lake.

In MMI survey work, which Goldcorp has completed a significant quantity of samples in the Red Lake Greenstone Belt, MMI is not a stand alone direct detection mineralization tool. MMI must always be used in conjunction with at least one other detection method (we prefer airborne magnetics and diamond drilling). Goldcorp's success in targeting mineralization is now better than 50% (1 in every 2 holes hits mineralization) when using MMI in regional grassroots exploration.

A program of MMI sampling on 25m line spacing with samples every 10m on line. 6 detailed line around high grade skarn mineralization near Upper Duck Lake and another 3 lines around new mineralization discovered north of Anderson Lake. A total of approximately 5000 samples and at a total anticipated cost of \$25,000. This program should commence immediately.

CERTIFICATE OF ANALYSIS

Work Order: 073425

To: Goldcorp Inc.
Attn: W. Paterson

Date : 12/08/03

P.O. Box 190 HWY 125
COCHENOUR
ONTARIO/CANADA/P0V 1L0

Copy 1 to

P.O. No. : Planet
Project No. : Sidace Lake
No. of Samples : 110 Soil (MMI)
Date Submitted : 10/07/03
Report Comprises : Cover Sheet plus
Pages 1 to 3

Distribution of unused material:
Pulps: RETURN
Rejects: RETURN

Certified By :

Dr. Hugh de Souza, General Manager

ISO 9002 REGISTERED

ISO 17025 Accredited for Specific Tests. SCC No. 456

Report Footer: L.N.R. = Listed not received I.S. = Insufficient Sample
n.a. = Not applicable -- = No result
*INF = Composition of this sample makes detection impossible by this method
M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Subject to SGS General Terms and Conditions.

Work Order: 073425

Date: 12/08/03

CERTIFICATE OF ANALYSIS

Work Order: 073428

To: Goldcorp Inc.
Attn: W. Paterson

Date : 28/07/03

P.O. Box 190 HWY 125
COCHENOUR
ONTARIO/CANADA/P0V 1L0

Copy 1 to :

P.O. No. : Planet
Project No. : Sidace Lake
No. of Samples : 114 Soil (MMI)
Date Submitted : 10/07/03
Report Comprises : Cover Sheet plus
Pages 1 to 3

Distribution of unused material:

Pulps: RETURN
Rejects: RETURN

Certified By

For Dr. Hugh de Souza, General Manager

ISO 9002 REGISTERED

ISO 17025 Accredited for Specific Tests. SCC No. 456

Report Footer: L.N.R. = Listed not received I.S. = Insufficient Sample
n.a. = Not applicable - = No result
*INF = Composition of this sample makes detection impossible by this method
M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Subject to SGS General Terms and Conditions

Work Order: 073428

Date: 28/07/03

CERTIFICATE OF ANALYSIS

Work Order: 073208

To: Goldcorp Inc.
Attn: W. Paterson

Date : 11/07/03

P.O. Box 190 HWY 125
COCHENOUR
ONTARIO/CANADA/P0V 1L0

Copy 1 to :

P.O. No. :
Project No. : PLANET JV
No. of Samples : 104 Soil (MMI)
Date Submitted : 27/06/03
Report Comprises : Cover Sheet plus
Pages 1 to 3

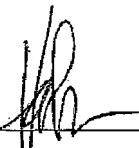

Note:

Duplicate results outside acceptance criteria due to sample inhomogeneity.

Distribution of unused material:

Pulps: RETURN
Rejects: RETURN

Certified By :

Dr. Hugh de Souza, General Manager

ISO 9002 REGISTERED

ISO 17025 Accredited for Specific Tests. SCC No. 456

Report Footer: L.N.R. = Listed not received I.S. = Insufficient Sample
n.a. = Not applicable -- = No result
*INF = Composition of this sample makes detection impossible by this method
M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Subject to SGS General Terms and Conditions

Work Order: 073208

MMI-F

CERTIFICATE OF ANALYSIS

Work Order: 074512

To: Goldcorp Inc.
Attn: W. Paterson

Date : 03/10/03

P.O. Box 190 HWY 125
COCHENOUR
ONTARIO/CANADA/P0V 1L0

Copy 1 to : /mdehn@goldcorp.com
Goldcorp.Inc.- M. Dehn

P.O. No. : Planet
Project No. : POH 073824
No. of Samples : 32 Soil (MMI)
Date Submitted : 23/09/03
Report Comprises : Cover Sheet plus
Pages 1 to 1

Distribution of unused material:

Pulps: RETURN
Rejects: RETURN

Certified By :

Dr. Hugh de Souza, General Manager

ISO 9002 REGISTERED

ISO 17025 Accredited for Specific Tests. SCC No. 456.

Report Footer: L.N.R. = Listed not received I.S. = Insufficient Sample
n.a. = Not applicable - = No result
*INF = Composition of this sample makes detection impossible by this method
M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Subject to SGS General Terms and Conditions

Work Order: 074512

Date: 03/10/03
