OREQUEST

SUMMARY

Band-Ore Resources Ltd. owns a 100% interest in the Thorne Property, located about 15 kilometres west of Timmins, Ontario, in the Abitibi Greenstone Belt. The Timmins area has a long and prolific history of exploration and mining activity. Geological conditions on the Thorne property are similar to other areas in the region that host gold mineralization. These include; the Destor-Porcupine Fault with which almost all the deposits in the area are spatially or genetically related; ultramafic intrusions spatially related to gold rich quartz-carbonate veins and altered quartz-feldspar porphyries similar to the one which hosts the McIntyre copper-gold-molybdenum deposit at Timmins.

There are a number of gold deposits and occurrences on and around the property. These include the Holmer Gold Mine, the Gowest-Hemlo Gold occurrence and the Rusk Lake and Bristol Lake showings. Drilling on the properties by previous operators returned a number of encouraging gold intercepts from quartz veins, quartz carbonate sulphide zones, altered ultramafic rocks and altered quartz-feldspar porphyries.

The Thorne property has been worked intermittently since 1937. Prior to 1993, much of that work concentrated on the Kapika Zone where Esso estimated a drill indicated reserve of 292,228 tons grading 0.072 oz/ton (2.453 g/t) gold (tonnage and grade not to NI 43-101 standards).

The Band-Ore property contains two distinct types of gold mineralization although both styles exhibit a strong spatial relationship to quartz-feldspar porphyry bodies. The Kapika Zone style of mineralization can be summarized as containing two distinct gold zones one hosted by a red magnetite bearing porphyry and the other within arsenopyrite-pyrite-quartz-ankerite veined sericitic metasediments. The second type and the one which appears to be contain the most economic potential lies within a sulphide mineralized termed the "Band-Ore Horizon", which is situated within a broad alteration deformation termed the Golden River Deformation Zone (GRDZ). The Band-Ore Horizon which consists of approximately 150 meter wide, strongly foliated, strongly altered (sericite-ankerite – pyrite altered metasediments. Gold mineralization is hosted within arsenopyrite-pyrite-ankerite-quartz veins and appears to be strongest proximal to porphyry contacts although some mineralization occurs within sericitic and carbonate altered pyritic porphyries. Prior to December 31, 2002, approximately 95 kilometers (94,933.3m) of drilling have been completed in 342 holes on the Kapika, Band-Ore Horizon and the GRDZ during the period of 1993 to 1998. An additional 54 holes (11,879.3 meters) were drilled on the Kapika Zone by Esso. During the 2003 calendar year, additional drilling was conducted by Band-Ore consisting of 46 holes, 10,535.5m.

In 1997, Band-Ore had commissioned Mr. Joe Spiteri and Spiteri Geological and Mining Consultants Inc. to review all the drilling to date to generate a mineral resource on the company's Golden River Zones. All of the 13 zones that collectively comprise the Golden River Zones, that in turn constitute the Spiteri resource estimate, are hosted within the 750m wide Golden River Deformation Zone. Mr Spiteri states that:

> *"the inferred resources estimated in 1997-98 on the Thorne Property totaling approximately 4 million tonnes of 3 g/t for about 400,000 contained gold ounces qualifies as a "Inferred Resource" under the Guidelines of NI 43-101."*

Extensive overburden coverage means outcrop exposure is limited so that geophysical exploration methods and diamond drilling are required for any planned future exploration. In part, electromagnetic methods are favoured but IP is now recognised as the most suitable method because the gold mineralization is associated with disseminated arsenopyrite and pyrite. Since 1996, a considerable amount of diamond drilling (approximately 117 kilometers) has been performed on the Thorne property, the majority of which was conducted along Golden River Deformation Zone. Very little of the drilling has been conducted in the area south of the Golden River Deformation Zone and north of the Destor – Porcupine Fault (DPF). The geology in this area is poorly understood due to lack of outcrop, and drill hole data. The Band-Ore Lower Footwall Fault Zone, one of the 13 Golden River gold zones, is a likely splay off of the DPF. Other parallel splays off the DPF could exist in the southern portion of the Band-Ore property. Band-Ore drilling since 1995 has been largely confined to the Golden River Deformation Zone north of the DPF, and several targets, both geological and geophysical, were left untested.

Due to overburden cover, lack of geological information, the exact location of the Destor Porcupine Fault zone on the Thorne property is interpretative. Ministry of Northern Development and Mines interpretation on regional geology maps shows the Destor Porcupine Fault as approximately 500 m south of previous interpretations. A total of seven IP anomalies remain untested that are situated in what appears to be a favourable geological setting north of the Destor-Porcupine. Three old drill holes were completed in the area of these IP anomalies, none of them intercepted the IP anomalies so the source of the anomalies has yet to be explained.

The work completed by Band-Ore from 1995-2003 has met the companies objectives and as outlined a mineral resource of approximately 400,000 ounces of gold (Spiteri 2002). The company has completed extensive exploration programs on the Thorne property since 1993. Numerous phases of work have been completed by Band-Ore since 1993 including both Phase I and Phase II as recommended in the June 30, 2003 OreQuest report.

The 2003 drilling program resulted in the discovery of four new gold bearing zones termed the: "No. 14 Zone", the "Red Porphyry Zone", the "Thibault Horizon" and the "Keno Zone. Gold mineralization occurs in strongly deformed, strongly altered (sericite, ankerite) sediments, variable mineralized with pyrite and arsenopyrite. Results returned a gold value of 9.59 g/t Au over a core length of 4.5 metres (GW-03-17), including 14.9 g/t Au over a core length of 2.7 metres. In addition, hole GW-03-29 returned a gold intersection of 3.11 g/t Au over a core length of 9.1 metres, including 4.74 g/t Au over a core length of 3.8m. Results in the other zones were encouraging although not as high as from the No. 14 zone. Generally, broad zones of alteration with weakly anomalous gold values were intercepted but the zones have not fully been tested. Further drilling is warranted on the # 14 zone, the Thibault Horizon, the Red Porphyry zone, and the Keno Zone as well as other untested IP anomalies.

Based on the successful completion of Phase I and II, a Phase III program of further drilling is recommended. The cost of the Phase III program is estimated at $1,650,000. The proposed program should consist of 50,000 feet (approximately 15,200m) of diamond drilling to follow-up the successes from the drilling completed in 2003. Thick overburden hampers any other type of exploration. Particular emphasis should be focussed towards drilling more holes in the No.14 Zone.

Other targets, including IP Zones developed in the previous work programs, should also be drilled. Additional work beyond Phase III, is contingent upon success in Phase III.

INTRODUCTION AND TERMS OF REFERENCE

This report presents a geological appraisal of the Thorne Property owned by Band-Ore Resources Ltd. and makes recommendations for further work. It is prepared by Orequest Consultants Ltd. for Band-Ore Resources Ltd. This report has been prepared to support a Band-Ore Annual Information Form and a proposed Band-Ore private placement financing and has been prepared under the terms set out in NI 43-101.

The information herein is derived from a review of the documents listed in the References and from information provided by Band-Ore. A complete list of the reports available to the author is found in the References section of this report. The author is familiar with the general area through involvement in numerous exploration programs in the general area on behalf of several other companies.

The property is located west of Timmins, Ontario (Figure 1), along the Destor -Porcupine Fault system, a geological structure that is at least spatially associated with most of the gold deposits and mines in the area. The author visited the Band-Ore Thorne property on June 23, 2003 with Band-Ore director and Qualified Person, Robert Duess P.Geo while the drilling program was in progress. The day's activities included a site visit to both Thorne East and Thorne West areas and a detailed review geophysical information and of certain sections of the core drilled to that date. A review of core sampling procedures was also conducted.

The material found in this technical report is an amalgamation of previous reports, program updates, consultant reports, and corporate press releases available for review. The author was greatly assisted by Mr. Robert Duess P.Geo., Vice President of Band-Ore who provided valuable input in the preparation of this report, in particular in supplying some of the necessary technical information required to complete this report. There were no limitations put on the author in preparation of this report with respect to Band-Ore information.

The author of this report is familiar with the subject matter covering the preceding and intervening years and the current publicly available body of data. A total of nine reports have been written in whole or in part by the author on nearby properties by the author in 1993-2002, five of the reports were written for Band-Ore. The previous OreQuest report titled, "*Summary Report on the Thorne Property, Bristol, Carscallen, Denton and Thorneloe Townships, Porcupine Mining Division, Ont., for Band-Ore Resources, June 30, 2002*" provides all the background details and complete lists of all exploration results completed 2000-2002. This report summarizes the previous work and primarily discusses the results of the work completed in 2003. Completed details of previous work are contained in the June 30, 2002 report. A complete list of the reports prepared on behalf of OreQuest Consultants Ltd. in the Band-Ore, Thorne area can be found in the References section of this report.

All reference to currency in this report is in Canadian dollars.

DISCLAIMER

OreQuest has prepared this report based upon information believed to be accurate at the time of completion, but which is not guaranteed. The author has relied on three principle sources of information for the data contained in this report as follows: Band-Ore Resources Ltd. technical files and government assessment reports and other company's corporate press releases available for review. Therefore in writing this technical paper the author relies on the truth and accuracy presented to us from the sources listed in the Reference section of this report. In addition, information in this report was obtained from recent press releases authorized for distribution into the public domain from the participating companies.

One of the purposes of this report is not to recalculate the resource figures generated by Mr. Spiteri but to recommend other areas of the property with the potential to discover additional mineralized bodies of similar or better grade. This report will not be recommending any additional drilling on the mineralized zones that have been drilled in detail in 1996-1997.

Band-Ore's management has provided a compilation on legal title of the properties. The detailed list of the individual claim particulars was provided by company President, Wayne O'Connor, who, in email letter dated correspondences to the author states that the claims are all in good standing. Band-Ore management has also stated that the Company is unaware of any environmental or other liabilities regarding the Thorne property.

PROPERTY DESCRIPTION AND LOCATION

The property is located in the Bristol and Thorneloe Townships, about 15 kilometres west of Timmins in north-eastern Ontario (Figure 1). Easy all-weather road access is provided by both Highway #101, which connects Timmins to points west about 1-2 km north of the property and Highway #144 to Sudbury which passes through the western portion of the property. A dirt road which follows along the north side of the Tatachikapika River, provides access to the interior of the west part of the Property. A dirt road off highway 144 south of the Tatachikapika River provides access to the central portion of the East part on the Thorne property.

The property consists of 161 contiguous unpatented mining claims, totalling 362 units, over an area of approximately 57.92 km^2. The claims are located in the Porcupine Mining Division, on NTS map 42A/6, on claim maps: Bristol Township G3998, Carscallen Township G3040, Denton Township G3224 and Thorneloe Township G3229 (Figure 2). A complete list of the claims can be located in Appendix I of this report. The claims have not been legally surveyed.

All claim are currently in good standing as per the list in Appendix I and will require annual assessment work requirements of $400 per unit ($64,400/year for the 161 claims) to keep the claims in good standing beyond their current listed expiry dates. If the phase of the exploration program recommended in this report for the property estimated to cost $1,650,000 is completed, expenditures will meet the assessment work requirements for many more years. If Band-Ore exceeds the minimum annual assessment expenditure for the staked claims, surplus expenditures can be utilized in future years to meet annual assessment requirements. Appendix I shows the current surplus expenditures available to Band-Ore for near term assessment requirements.

Porcupine Mining Division
Ontario
Dec 2003

Band-Ore holds a 100% interest, subject to certain underlying NSR obligations, in the claims which have, since 1992, been acquired by staking or purchase from various owners. Figure 2 shows the various groups subjected to the different royalty interests are separated by the different colour codes. Appendix I lists the various different royalty interests. Title information has been provided by the company; a title search has not been completed by the author. Complete title information and details of the terms of any property agreements can be obtained from the company or its solicitor. A detailed list of the individual claim particulars was provided by Wayne O'Connor, (President Band-Ore Resources) who states in an email letter dated Dec 19, 2003 to the author, that the all claims are in good standing.

There are no known environmental liabilities on the Thorne property, which is the subject of this report. The author is not aware of any unusual permit requirements for the claims during the early exploration phases other than standard permitting for any issues related to water crossings which requires the installations of bridges.

ACCESSIBILITY, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE AND PHYSIOGRAPHY

The property is located in the Bristol and Thorneloe Townships, about 15 kilometres west of Timmins in north-eastern Ontario (Figure 1). Easy all-weather road access is provided by both Highway #101, which connects Timmins to points west about 1-2 km north of the property and Highway #144 to Sudbury which passes through the western portion of the property. A dirt road which follows along the north side of the Tatachikapika River, provides access to the interior of the west part of the Property. A dirt road off highway 144 south of the Tatachikapika River provides access to the central portion of the east part on the Thorne property.

The property lies in an area of northern Ontario where topographic relief varies between 15-25m with elevations of approximately 950-1000m asl. The property is mainly covered by glacial overburden and reworked aeolian sands commonly found along the banks of the Tatachikapika River. Results of a 1984 overburden drilling program indicates that the overburden varies from 6-40 m in depth and that the bedrock topography is quite rugged. Occasional outcrops can be observed along the banks of the Tatachikapika River.

The claims contain abundant water. In addition to numerous swamps and small unnamed creeks, the Tatachikapika River flows through the middle of the property with adequate water for all advanced exploration or development requirements. The Wawaiten hydro-electric power dam is located immediately east of the eastern boundary of the property.

The eastern half of the property is covered by second growth white spruce forest. Elsewhere, spruce, birch and poplar are the most common vegetation, with tag alders and cedar thickets abundant in the swampy areas of the property. Climate is typical of the Canadian Shield, moderately dry summers with temperatures as high as 40^0C and snowy winters with temperatures as low as -40^0C. Exploration can take place year round with minor breaks during the spring thaw and winter freeze up, mining can take place all year around.

Abundant lakes, bogs and swamps with low relief characterize the region. Water is extremely abundant, drainage is immature and randomly scattered and is readily available in sufficient

quantities to supply virtually any mining need. Power is readily available through nearby existing power grid. The property covers a large area with plenty of space for the building of infrastructure for any advanced exploration or development.

The property has the sufficiency of surface rights for future exploration or mining operations including potential tailings storage areas, potential waste disposal areas, heap leach pads areas and potential processing plant sites. The nearby city of Timmins is the major mining centre in northern Ontario; all mining personnel, equipment and supplies can easily be accessed from the city.

HISTORY

There is a long history of exploration on the Thorne property and in its vicinity as summarized from the assessment files below:

1947 - Gertie Gold Syndicate
- minor geological mapping followed by 1183 feet of diamond drilling in three holes on Thorne claim #956082. All assays less than 0.02 oz/ton Au from small quartz veins within greywackes.

1958 - Hollinger Gold Mines
- magnetic and VLF-EM surveys, geological mapping and 2398 feet of diamond drilling to the west of the property to test the conductors outlined by the geophysics.
- no assays were submitted.

1981 - Preussag Canada Ltd.
- magnetic, VLF-EM and HLEM surveys followed by eleven holes (2371 feet) of drilling centred just outside the north-west corner of the Thorne property.
- hole TW 81-1 returned 0.18 oz/ton gold over 2.0 metres and TW 81-2 returned 0.13 oz/ton gold over 4.5 metres from a red pyritic syenite and the contact between andesitic and ultramafic rocks.

1984-1985 - J. Croxall/Noranda
- drilling of three holes north-west of the Thorne property; no assays submitted.

1985-1988 - Esso Minerals Canada
- several generations of magnetic, electromagnetic, IP and HLEM geophysical surveys.
- seven reverse circulation overburden holes (529 feet total)
- 55 diamond drill holes totalling 10,856 m (35,610.63 ft)
- Esso has done a preliminary grade and tonnage calculation for the Kapika Zone using drill intercepts from 14 holes (T 11-15, 28, 29, 35 and 45-50). They report that the Zone contains 292,228 tons grading 0.072 oz/ton (2.453 g/t) gold to a depth of 200m. The historic resource figures generated by Esso have not been redefined to conform to the CIM approved standards as required in NI 43-101. This resource figure is not considered relevant for the purpose of this report because the author cannot confirm that the calculation conforms to accepted classification standards under National Instrument 43-101. The author cannot verify these figures or determine their reliability. No further work on these resource estimates is known to have been completed.

1987 - J. Croxall/Highwood Resources Ltd.
- three diamond drill holes (399.9 m) encountered mafic volcanics and intrusive complex just outside claim group to the north-west.

1989 - J. Croxall/Mintek Resources

- stripping, magnetic and VLF-EM geophysical surveys and one drill hole (89-1) in claim #P1177817 returned 0.013 oz/ton gold over 1.1 metre from altered sediments.

1992 - Band-Ore Resources

- options the single Croxall claim in what in now the central portion of the present day Thorne property.

1993 - Band-Ore Resources

- one 155 m drill hole on claim #P1177817 to test an IP anomaly. Drill hole intersected a 16 m wide altered metasediment with gold values up to 2.95 g/t over 0.6m.

1994 - Band-Ore Resources

- 1.3 kilometre magnetometer survey completed. Additional ground acquired.

1995 to 1998 Band-Ore Resources

A drilling program which commenced in late 1995 led to a major gold discovery in 1996. Band-Ore conducted extensive exploration programs on the property during 1996 to 1998. A summary of this work has been derived from the 1997 Rosatelli report, as follows:

1995 - Band-Ore Resources

- Diamond drill of TH-95-1 and TH 95-2 (Jan-Feb), plus TH-95-3 and TH-95-4, a total of 909m testing the Kapika Zone. Anomalous gold was detected in silicified, sericitized and ankeritized metasediments.
- 13.725 km IP survey over the Kapika Zone and in the immediate vicinity.
- 6.125 km of gradient IP survey over anomalous areas.
- 4 drill holes, TH-95-5 to TH-95-8 (783 meters) on the Kapika Zone. Hole TH-95-8 was drilled to the north but was collared in strongly sericitized and ankeritized metasediments with arsenopyrite and pyrite that were located south of the Kapika Zone.

1996 - Band-Ore Resources

- Diamond drilling of TH-96-9 in January from north to south testing the altered and mineralized sediments intersected in TH-95-8. Discovery hole, this hole returned a value of 0.122 oz/ton over 6.5m from a new alteration zone, the Band-Ore horizon.
- Property wide IP and ground magnetometer surveys.
- 119 drill holes (TH-96-9 to TH-96-127) totalling 33,859.8 meters. The author visited the Thorne property during this stage of the drilling.
- Discovery of the western extension of the Band-Ore horizon. 28 drill holes completed (TW-96-1 to TW-96-28) totalling 8,488.1 m.

1997 - Band-Ore Resources

- 124 diamond drill holes (TH-97-128 to TH-97-251) totalling 33,631.2 meters
- 62 diamond drill holes (TW-97-29 to TW-97-90) totalling 17,107.2 meters drilled on the western mineralized horizon.
- baseline environmental studies initiated but never completed, no results available.

At the completion of the 1995 drill testing of both the Kapika Zone and its western extension in the first eight holes, the company decided to shift its attention to the down dip projection of the Kapika Zone. Diamond drill hole TH 96-12 intersected a strongly altered, deformed and well mineralized zone that returned a value of 0.255 oz/ton (8.74 g/t) gold over a length of 60 ft (18.3 m) including a higher grade portion of 0.464 oz/t (15.91 g/t) over 30.5 ft (9.3 m). The zone is a highly

altered silicified, sericitized and carbonatized zone with pyrite and arsenopyrite mineralization. The presence of disseminated sulphides appears to generate an excellent IP target. The auriferous mineralization is related to a strong IP anomaly greater than 1,000 m in length. The new discovery, which lies approximately 300 m south of the Kapika Zone, has now been intersected by a many drill holes over a four kilometer length. These new gold discoveries are now referred to as the "Gold River Zones". The Gold River Zones lie within the "Band-Ore Horizon". The Band-Ore Horizon appears to be near vertical and is located just north of the Destor-Porcupine Fault within a broad alteration halo, approximately 750m wide, known as the "Golden River Deformation Zone" (GRDZ) that remains largely untested over approximately six kilometres of claims currently held by Band-Ore

Drilling to date has determined that the gold mineralization within the Golden River Deformation Zone (GRDZ) and more particularly within the Band-Ore Horizon, is hosted by Archean aged clastic metasediments, consisting of near vertical siltstones, thickly bedded argillites, arenite and conglomerates with minor quartz feldspar porphyries. The zone is a highly altered silicified sericitized and carbonatized zone with pyrite and arsenopyrite mineralization. There appears to be a broad envelope of sericite ankerite alteration surrounding the gold zones with minor fuchsite, montmorillonite and quartz-ankerite veining. The stratigraphy varies in dips from sub-vertical to 70° to the north but generally strikes east-west. The shear zones also strike east-west and generally dip steeply north. It appears the hydrothermal alteration and mineralization intersected to date is contained within a deformation zone bounded to the north and south by major faults.

To the end of 2002, approximately 93 kilometers (93,086.3 meters) of drilling have been completed in 333 holes on the Band-Ore Horizon between Jan 16, 1996 and Dec 7, 1997. An additional 63 holes (13,725.8 meters) were drilled on the Kapika Zone by both Esso and Band-Ore.

TABLE I -THORNE PROPERTY DRILLING SUMMARY

Gold Zones	Number of Holes	Total length (meters)
Kapika		
Esso Kapika 1985-88	54	11,879.3
Band-Ore Kapika 93	1	155.0
Band-Ore Kapika 95	8	1,691.5
Kapika Total	63	13,725.8
Thorne East (including South and Lower Footwall Zone)		
Band-Ore TH 96	119	33,859.8
Band-Ore TH 97	124	33,631.2
Thorne East Total	243	67,491.0
Thorne West		
Band-Ore TW 96	28	8,488.1
Band-Ore TW 97	62	17,107.2
Thorne West Total	90	25,595.3

The Band-Ore Horizon lies approximately 150 m south of the Kapika Zone and lies between Band-Ore gridlines L16+45E to L60+00E. Drilling of the Horizon has identified four distinct gold bearing zones: South Zone, Golden River West Zone (a.k.a. Thorne West Zone), Lower Footwall Fault Zone, and Golden River East Zone (a.k.a. Thorne East Zone). A description of each zone is contained in the June 30, 2002 OreQuest report and will not be repeated in this report.

There has been no known mineral production from the Thorne property. Since the date of the last OreQuest report (June 30, 2002), Band-Ore has spent approximately $880,000 on the Thorne project and since 1995 has spent a total of approximately $8.7 million on the project

GEOLOGICAL SETTING

The Thorne property lies at the western end of the Abitibi Greenstone Belt. The Abitibi Greenstone Belt is a belt of Precambrian (Archean) aged metavolcanic and metasedimentary rocks that extends across north-eastern Ontario and north-western Quebec. The rocks consist of a variety of mafic to felsic volcanics, related volcaniclastic sediments and detrital and chemical sediments and felsic to ultramafic intrusives. In the immediate vicinity of the property (Figure 3), mafic volcanic flows and pyroclastics, felsic volcanic flows, and sedimentary units from conglomerates to argillites are present. Ultramafic bodies, felsic intrusives and ubiquitous diabase dykes, have intruded these units.

There are a number of faults in the vicinity of the property, which generally mimic the structural elements typical of the Abitibi Greenstone Belt. The faults include a north to north-westerly set and the earlier aged east-west Destor -Porcupine Fault or splays thereof. The Destor-Porcupine Fault is a major structural break which is mapped from west of Timmins to the east to at least the Ontario and Quebec border, but is probably part of a larger 440 kilometre long feature which extends from the Kapuskasing Structure on the west to the Grenville Front on the east (Pyke, 1982). Most of the gold deposits in the Timmins area are spatially related to the area north of the Destor-Porcupine Fault. The southern portion of the property is underlain by the Tisdale group of ultramafic flows and intrusives and the Deloro group of felsic to intermediate calc-alkalic metavolcanics. The Destor-Porcupine Fault separates the two groups. In this area the Destor-Porcupine fault is a complex structure of a number of splays and segments off-set by north-westerly faults. The largest off-set, six kilometres as indicated by the regional aeromagnetic map, occurs across the Mattagami fault. A reinterpretation of the regional aeromagnetics (Figure 4) shows the offset and therefore shows the Destor Porcupine Fault as passing through the southern portion of the Thorne property (Figure 5).

The Thorne property is predominately underlain by a metasedimentary sequence thought to be Porcupine and/or Timiskaming Group (Figure 6). Three distinct metamorphosed rock types comprise the metasedimentary group: argillite, arenite and conglomerate. The argillite is fine grained, thin bedded, soft and generally black to grey in colour. Pyrite generally forms up to 1% cubic crystals in unaltered rock and up to 5% in more altered rock. Most of the property is underlain by the argillite, medium to coarse grained grey arenite and a polymitic conglomerate forming the remainder of the metasedimentary sequence. Cubic pyrite can occur up to 1% in an unaltered version of either rock, while disseminated pyrite can occur up to 20% in altered conglomerates.

Dec 2003
Geology Revised From: Ayer,J.A. and Trowell, N.F. 1998.Geological compilation of the Timmins area, Abitibi greenstone belt; Ontario geological Survey, Preliminary Map P.3379, scale 1:100 000

One of the most economically important features on the property are steeply dipping, altered quartz feldspar porphyry intrusives within strongly deformed shear zones. Many of the old drill holes intersected the favourable auriferous shear zone. The mineralized porphyries vary in composition from a quartz feldspar porphyry, to a pyritic porphyry, to a red magnetite bearing pyritic porphyry. The porphyries have been subjected to intense shearing characterized by sericitization, silicification and hematitic alteration. Gold is associated with secondary pyrite or can also be associated to a lesser degree with arsenopyrite. Quartz veining is evident but is not generally auriferous. There is one main shear, with at least two identifiable subsidiary shear zones parallel to the main shear.

DEPOSIT TYPES

The economic importance of base and precious metal production from the Abitibi Greenstone Belt in general and the Timmins area in particular, is well known. Since the discovery of gold at Timmins in 1909, over 30 mines have been put into production, producing more than 60 million ounces of gold. Base metals have been produced from the McIntyre Mine since 1953 and from the world class Kidd Creek Mine since 1965. The McIntyre Mine consists of a number of ore shoots totalling about eight million tons at a cut-off grade of 0.7% copper but the entire deposit contains more than 80 million tons of mineralization (Pyke, 1982).

The gold mineralization in the area occurs mainly in quartz-ankerite and quartz-calcite veins which also contain pyrite and a number of other accessory minerals. Pyrite also invades the wall rock adjacent to the veins. Spatially, the gold deposits are related to mafic intrusions and all occur in close proximity to major faults such as the Destor-Porcupine Fault. Altered quartz-feldspar porphyries, such as the Pearl Lake Porphyry, which is associated with the McIntyre Deposit, are also important host rocks in the area. Volcanogenic massive sulphide deposits, like the Kidd Creek deposit, occur in felsic volcanic piles. Although these base metal deposits form an important component of the metallogeny of the area, the Band-Ore property presents a gold exploration opportunity.

MINERALIZATION

Several gold occurrences are located in the immediate vicinity of the property (Figure 4). These include (further details are located in the "Adjacent Properties" section of this report):

1. The Holmer Gold Mine, located close to the northern border of the Thorne property.
2. The Gowest Amalgamated/Hemlo Gold property, adjoining the Thorne property to the west.
3. The Rusk showing, occurs on the Thunder Creek property (currently under option from Band-Ore to Lakeshore Gold).
4. The Bristol Lake showing, located less than one kilometre north of the Thorne property.
5. The Golden River Zones where gold mineralization is hosted within arsenopyrite-pyrite-ankerite-quartz altered sediments. Mineralization appears to be strongest proximal to porphyry contacts although some mineralization occurs within sericitic and carbonate altered pyritic porphyries.

One of the most economically important features on the property are steeply dipping, altered quartz feldspar porphyry intrusives within strongly deformed shear zones. The sheared altered and mineralized porphyries have been drill tested by many drill holes. Many of the drill holes intersected the favourable auriferous shear zone. The mineralized porphyries vary in composition from a quartz

feldspar porphyry, to a pyritic porphyry, to a red magnetite bearing pyritic porphyry. The porphyries have been subjected to intense shearing characterized by sericitization, silicification and hematitic alteration. Gold is associated with secondary pyrite or can also be associated to a lesser degree with arsenopyrite. Quartz veining is evident but is not generally auriferous. There is one main shear, with at least two identifiable subsidiary shear zones parallel to the main shear.

The Kapika Zone has been tested by 43 drill holes (Figure 5). The geology of the zone has been extrapolated from the drill intersections, as there are no outcrops in the area. The Kapika Zone lies within altered quartz and/or feldspar porphyries hosted within an assemblage of turbiditic metasedimentary rocks at the easternmost end of the three kilometres altered shear zone.

The mineralization within the porphyries is contained in a sericitic rich shear zone that varies in width from 20 to 70 metres hosted by thin bedded argillite and conglomerates and other mixed metasediments. The shear zone generally strikes 105° and is steeply dipping. The main mineralized zone extends over 100 m while the mineralized host porphyry complex is observed in drill holes over a length of 400 m. The alteration package within the shear zone consists of quartz carbonate, (generally ankerite), pyrite, hematite and magnetite as well as sericitization and silicification. The altered porphyry tends to be red to light orange, well foliated to locally massive and contains 1-3% fine-medium grained disseminated magnetite (MacPherson, 1988).

The gold mineralization is related to increased disseminated pyrite content. Within the main Kapika Zone, Esso has identified at least five separate gold zones; three zones in the porphyry and two zones in the sericitic shear zone. No deep drilling to test the strong shear porphyry structure below the 200 m level has been done. Esso has done a preliminary grade and tonnage calculation for the Kapika Zone using drill intercepts from 14 holes (T 11-15, 28, 29, 35 and 45-50). They report that the Zone contains 292,228 tons grading 0.072 oz/ton (2.453 g/t) gold to a depth of 200m. This resource figure is not considered relevant for the purpose of this report because the author cannot confirm that the calculation conforms to accepted classification standards under National Instrument 43-101. The author cannot verify these figures or determine their reliability. No further work on these resource estimates is known to have been completed.

The Thorne property contains two distinct types of gold mineralization although both styles exhibit a strong spatial relationship to quartz-feldspar porphyry bodies. The Kapika Zone style of mineralization can be summarized as containing two distinct gold zones one hosted by a red magnetite bearing porphyry and the other within arsenopyrite-pyrite-quartz-ankerite veined sericitic metasediments.

The second type and the one which appears to contain the most economic potential, has been titled the Golden River Zone. Gold mineralization is hosted within arsenopyrite-pyrite-ankerite-quartz veins and appears to be strongest proximal to porphyry contacts although some mineralization occurs within sericitic and carbonate altered pyritic porphyries. Mineralized zones occur within a broad alteration deformation zone termed the Golden River Deformation Zone (GRDZ) that strikes across the Thorne property in an east – west direction. Mineralization intersected to date in the approximately 150m wide Band-Ore Horizon within the approximately 750m wide GRDZ, consists of arsenopyrite and pyrite with minor pyrrhotite, tetrahedrite, stibnite, sphalerite, berthierite, boulangerite, as well as native gold and native antimony (Payne, 1996). The gold appears to be

contemporaneous with the arsenopyrite-pyrite mineralization. The gold is extremely fine grained, and therefore is rarely observed without a microscope. Visible gold was reported in only seven holes which resulted in corresponding high gold intercepts such as 2.85 oz/ton (97.71 g/t) over 1.0 m (TH –97-222) and 16.0 g/t (4.90 oz/ton) over 1.0 m (TH-97-223). There appears to be a close relationship between the occurrence of fine-grained, anhedral to subhedral stibnite and higher-grade gold intervals. Arsenopyrite can occur as fine grained to coarse-grained crystals in veins, disseminations and as layers or bands in the altered host rocks. Overall sulphide percentage can vary from 5-10% to greater than 20%. Pyrite also varies from fine grained to coarse euhedral crystals as well as dissemination's, or as sulphide stringers or layers of more massive mineralization with an overall percentage of 5-10% sulphide. Gold occurs as intergrowth associated with the arsenopyrite and as inclusions in the pyrite.

EXPLORATION

During the period of Oct 1 2002 to Nov. 30, 2002, Band-Ore resumed exploration activities on the Thorne property. During this period exploration programs consisting of linecutting, ground and airborne magnetic surveying, induced polarization survey and diamond drilling was performed. A summary of this recent exploration is as follows:

- Oct 2002 to Dec. 2002:
  An exploration program consisting of line-cutting, ground magnetic, and I.P surveying was conducted over a selected portion of the south part of the property area. The area surveyed had not been subject to ground geophysical surveying conducted during the 1995 to 1998 exploration period. A total of 15 km of grid lines were established, with the base line oriented in an east west direction, and perpendicular cross lines oriented in a north – south direction. Grid lines were picketed at 25m intervals. Ground magnetic surveying was conducted over all 15 km of grid lines, with magnetic readings recorded every 12.5m. Two days of I.P. surveying (using "a" spacing of 50 m, reading n1 to n6 was conducted. Portions of line 2W, 0 and 2E were surveyed. All work was conducted by Vision Exploration, Timmins.

- Jan 2003 to Feb 2003:
  Six diamond drill holes (GS-03-1 to 6, BQ sized core), totaling 1,680 metres were drilled.

- April 2003:
  A detailed airborne (fixed wing) magnetic survey was completed overt the southern ½ of the Thorne property. Airborne surveying was performed by TerraQuest Limited. The survey was conducted at 50m flight line spacing, with flight lines oriented in a north-easterly direction. Data processing was conduced by Scott Hogg and Associates. A total of 748 km of airborne surveying was completed.

- May 2003 to Nov. 2003:
  40 holes totaling 8,855.5 metres were completed.

- 20 Sept. to 29 Sept 2003:
  Detailed airborne magnetic surveying was completed over the northern portion of the Thorne. Airborne surveying was completed by TerraQuest Ltd. The survey was conducted at 75 m

flight line spacing, with flight lines orientated in an east – west direction. Data processing and levelling with previous airborne survey was conducted by Scott Hogg & Associates.
A total of 630 km of airborne surveying was completed.

DRILLING

Band-Ore completed 46 diamond drill holes totaling 10,535,5 metres (34,565.3 feet) on the Thorne Property in 2003. All drilling was conducted by Norex Drilling Ltd. Timmins Ontario. All drill core was logged by either Robert Duess (Vice President Exploration, Band-Ore Resources) and/or Mike Leahey, P. Geo. under the direct supervision of Mr. Duess. All drilling was conducted in order to test geophysical and/or geologic targets which are not associated with the Golden River Zones (East and West) and targets which were not tested during previously exploration programs.

The 2003 drilling program resulted in the discovery of four new gold bearing zones termed the: "No. 14 Zone", the "Red Porphyry Zone", the "Thibault Horizon" and the "Keno Zone" (Fig 7).

No. 14 Zone

The most significant of the new discoveries is the "No. 14 Zone." This zone is located west of the Tatachikapika River, approximately 300 metres east south east of the Golden River West Zone. Twenty-two holes totaling 4,421.6 metres were drilled in the area of the No. 14 Zone.

Dec 2003

The No.14 Zone is situated along the southern part of the Golden River Deformation Zone. The style of gold mineralization of the "No.14 Zone" is similar to the gold mineralization, which occurs in the main Golden River Zones. Gold mineralization occurs in strongly deformed, strongly altered (sericite, ankerite) sediments, variable mineralized with pyrite and arsenopyrite. The gold mineralization appears to have a spatial relationship to porphyry sills, which have also been intensely altered. A detailed plan of drill holes in the area of the No.14 zone occurs as Figure 8, and an idealized section of the No.14 Zone occurs as Figure 9. Length weighted average gold grades from the No. 14 zone, include:

width as possible but since the geology is not well understood at this early stage of the exploration program, true width is not known.

Hole GW-03-11 intersected diabase at 41.4 metres, and was terminated in diabase at 95m. No results are shown for holes GW-03-15, and GW-03-32, as both these holes collared in diabase, and were terminated in diabase.

Red Porphyry Zone

The Red Porphyry Zone is located on the west side of the Tatachikapika River, approximately 1000 metres north of the "No. 14 Zone." This zone was discovered by drill testing an I.P. anomaly which had not during previous drilling programs. A total of seven holes, representing a total of 1,356.2 m were drilled in the area of the Red Porphyry Zone.

TABLE IV - RED PORPHYRY ZONE DRILLING SUMMARY

Drill Hole	Northing	Easting	Total depth (m)	Drill size
GS-03-05	5352825.0	456400.0	200.00	BQ
GW-03-10	5356150.0	460000.0	65.60	BQ
GW03-10A	5356153.0	460000.0	276.00	BQ
GW-03-14	5356300.0	460000.0	365.00	BQ
GW-03-24	5356150.0	459950.0	193.00	BQ
GW-03-25	5356150.0	460025.0	56.00	NQ
GW-03-26	5356175.0	459975.0	200.60	NQ
7 holes			**1356.2m**	

Hole GW-03-10 encountered technical difficulties with casing and abundant boulders in overburden. Drilling was terminated at 65.6meters. The hole was re drilled as hole GW-03-10A, re-positioned approximately 3m to the north of the original location. Hole GW-03-25 collared in diabase and was terminated in diabase at 56m.

The geological setting of the Red porphyry zone appears to be very similar to Kapika Zone, discovered by Esso during the 1980s. Gold mineralization occurs within red, hematite altered porphyry, variably silicified, carbonate and sericite altered, and variably mineralized with up to 5% disseminated pyrite. It is interesting to note that the porphyry body is moderately to weakly magnetic in places (locally containing ½ % disseminated magnetite). However, the magnetite content, appears to be on insignificant quantity so that the porphyry body was not detected by airborne and/or ground magnetite surveying. Length weighted average gold grades for the Red Porphyry Zone are included in the following table (true width unknown):

TABLE V - RED PORPHYRY ZONE DRILL RESULTS

Hole	From (m)	To (m)	Core Length (m)	Averaged Grade Au (g/t)
GW-03-05	100.0	102.5	2.50	0.61
GW-03-10	59.0	72.5	13.50	0.26
	80.0	111.5	31.50	0.37
GW-03-14				0.49

Thibault Horizon:

A total of five holes were drilled to test the "Thibault Horizon" which is located in the southern part of the property area, approximately on kilometer south of the Golden River Zone.

TABLE VI - THIBAULT HORIZON DRILLING SUMMARY

Drill Hole	Northing	Easting	Total depth (m)	Drill size

GW-03-09	5355917	460125	248	BQ
5 holes			**1513m**	

The 2003 drilling has identified the Thibault Horizon as a broad alteration / deformation zone which strikes in an east west direction across the southern portion of the Thorne property, and dips steeply to the north. The Thibault Horizon consists of a highly altered (sericite, fuchsite, quartz carbonate) rock variable mineralized with pyrite and arsenopyrite. This horizon is located north of the Destor – Porcupine Deformation Zone, and appears to strike in an east – west direction across the Thorne property.

Length weighted average gold grades from drilling on the Thibault Horizon include (true width unknown):

- GS-03-04: 0.40 g/t Au across core length of 1.0m
- GS-03-09: 0.26 g/t Au across core length of 9.4m
- GS-03-10: 0.50 g/t Au across core length of 1.5m and 1.7 g/t Au over 0.5m
- GS-03-12: 0.26 g/t Au across core length of 1.5m
- GW-03-9: 0.089 g/t Au across core length of 1.5m

Keno Zone

The "Keno Zone" is located in the south central portion of the Thorne Property, approximately on 1.5 km south of the Golden River Zone. This zone was discovered by drill testing an I.P. anomaly that was defined during the field exploration programs conducted during the fall of 2002. A total of five holes, representing a total of 1,534 m were drilled in the area of the "Keno Zone".

TABLE VII - KENO ZONE DRILLING SUMMARY

Drill Hole	Northing	Easting	Total depth (m)	Drill size
GS-03-01	5353100	460000	323	BQ
GS-03-02	5353275	460000	338	BQ
GS-03-03	5353450	460000	338	BQ
GS-03-07	5353228	460200	284	BQ
GS-03-08	5353181	459953	251	BQ
5 holes			**1534m**	

Gold mineralization occurs within a zone (s) of highly altered (sericite – quartz- carbonate – fuchsite) occurring within a porphyry – felsic intrusive complex. Hole GS-03-01 returned the best gold intersection of 0.50g/t over a core length of 5.4 metres, with values ranging from 0.05 to 1.52 g/t Au. Hole GS-03-7 returned a value of 0.44 g/t Au over a core length of 1.5m, and 0.12 g/t Au over 1.4m was encountered in drill hole GS-03-8. True width are unknown in all the quoted intercepts.

Other Targets:

Seven holes, totaling 1,545m were drilled to test other targets on the Thorne Property.

TABLE VIII - OTHER TARGETS DRILLING SUMMARY

Drill Hole	Northing	Easting	Total depth (m)	Drill size	Target
GS-03-05	5352825	456400	200.0	BQ	I.P. Target
GS-03-06	5353100	456400	152.0	BQ	I.P. Target
GW-03-03	5355867	459520	215.0	BQ	I.P. Target
GW-03-30	5356275	460300	239.3	NQ	I.P. Target
GW-03-04	5355850	459424	251.3	BQ	I.P. Target
GW-03-06	5356050	460300	271.4	BQ	I.P. Target
GW-03-08	5355917	459520	216.0	BQ	I.P. Target
7 holes			**1057.6m**		

Low gold values were returned in all the holes, only one interval returned a 2.2m interval of 0.51g/t Au (GW-03-03). The other holes all contained values less than 0.4g/t Au. Although the values were low, the concept of drilling IP anomalies is sound as some the other better mineralized sections (i.e. the Band-Ore Horizon) are related to IP anomalies.

SAMPLING METHOD, APPROACH AND SECURITY

The following is a general description of the sampling methods utilized, approach taken and security measures in place during the 2003 drill program. The information provided in this section was obtained from Mr. R. Duess, the Band-Ore technical director, and V.P Exploration. The author was present to observe these procedures and confirm to their accuracy. All drill core logging, including the selection of sample intervals, is conducted by, or under the supervision of Professional Geologists, members of the Association of Professional Geologists of Ontario.

Core intervals that require sampling are marked off and tagged, with sample intervals rarely longer than 1.5 metres, and rarely shorter than 1.0 metres. Core splitting is conducted by using hydraulic splitters, and occasionally by core cutting saws using diamond blades. Approximately half of the sample is bagged for assay purposes, and the remaining half is placed back in the core box in the same order it occurs, and the core is retained for future reference purposes. A duplicate sample tag is placed at the beginning of each sample in the core box to ensure that each sample would be identifiable both by logged footage interval, and by the location of the sample tag. Under no circumstances is the entire core bagged and sent for assay during the sampling procedure.

For hydraulic splitting, pieces of core, including the "fines" are carefully collected and placed in plastic sample bags. At the end of each sample interval, the splitter and the immediate work top areas are swept clean to avoid cross contamination between samples. For sawn core, the core is cut in

half by a diamond cutting saw using water. Each piece of core is rinsed prior to being bagged. Individual split core samples are placed in individual plastic bags, tagged, and immediately secured using nylon ties. Individual samples are then placed in nylon shipping bags, secured with a security seal, and shipped to the laboratory for analysis. Samples which are awaiting shipment are stored in a secured building.

All gold assaying is performed by Swastika Laboratories, Swastika, Ontario, or ALS Chemex Chimitec, Val d'Or, Quebec, using a 30g standard fire assay with an AA finish. Both laboratories participate in the "Proficiency Testing Program for Mineral Analysis Laboratories", a testing program which is conducted bi-annually by the Standards Council of Canada. Both laboratories have obtained a "Certificate of Laboratory Proficiency."

SAMPLE PREPARATION AND ANALYSIS

During the 2003 drill program, Band-Ore employed two separate laboratories to process its drill core samples. Approximately 50 of the assaying was performed by Swastika Laboratories, and approximately 50% was conducted by ALS Chemex Chimitec in Val d'Or, Quebec. Gold assaying was, as reported to the author by Band-Ore personnel, by standard fire assay techniques with standard internal laboratory quality control typical of Canadian labs. Swastika Laboratories, and Chemex Chimitec are both certified Canadian. The author is unaware if ISO certification was in place for any of the three labs during the 1995-1998 exploration programs. Swastika Laboratories does not have ISO certification at this time although is in the process of receiving the ISO certification. The other two labs both currently have ISO certification.

DATA VERIFICATION

Data verification has been conducted on drilling conducted by Band-Ore during the 1995 to 1998 period. An independent geologist, Mr. J. Spiteri of Spiteri Geological and Mining Consultants Inc. (SGM) completed a quality control and data verification program on the drill core from three of the mineralized zones on the Thorne property. He selected 206 samples of drill core and sent them to a second lab for analysis. The following is his summary of this program from a July 27, 1997 memo to Band-Ore.

> *"To summarize, SGM selected 206 sample intervals for check assay and 9 intervals (3 from each zone) for specific gravity measurement. The distribution of the assay database was as follows:*

Zone	***Samples Collected for QC***
West	*69*
Lower Fault	*55*
East	*82*
TOTAL	*206*

> *In all cases the remaining "half" of the core was sent for measurement. All the samples were selected from assay intervals deemed to be part of the mineralized zone. Wherever possible, complete "ore" intervals were selected to simulate a complete cut across the deposit.*

The sample preparation work commissioned by SGM was performed by Chemex Laboratories in Timmins, while the analysis was performed in Mississauga.

The correlation coefficient for the complete data base is greater than 0.95, which is statistically good, in particular because we are comparing separate halves of core (i.e. a coarse sample). With the exception of 2 or 3 statistical outliers the scatter of the overall data was found to be good. It should be noted, however, that for values greater than 10 g/t Swastika Laboratories shows a high bias in both the East and West Zones (but not the LFZ). This same bias is apparent in Figure 4 of the July 17, 1997 SGM Report. This figure compared 84 originals and rejects from Swastika and Bondar-Clegg. The fact that a similar bias occurs between originals/rejects and two halves of the core, leads me to believe that the problem is not with the core splitting. It is recommended that the pulps or rejects presently being stored with Chemex be sent to Swastika for re-assay.

The specific gravity measurements show very little variation from zone to zone, regardless of sulphide concentration. The average being 2.8."

After a careful review of the sampling procedure and a review of the independent QC/data verification completed by Spiteri in 1997, it was the authors' opinion at the time that additional data verification for the Spiteri work. Therefore, the author is of the opinion that the previous sampling meets the standards set out in NI 43-101.

The author took five duplicate core samples from one of the drill holes during the 2003 site visit. The duplicates were analyzed in Vancouver by iPL Laboratories using the same procedures as ALS Chemex Chimitec, one of the labs used by Band-Ore and returned similar analytical results. Band-Ore Resources also undertakes a routine QC / QA (quality control/quality assurance) program in addition to any programs employed by the individual laboratories, which was designed by the author. A minimum of 4% of samples submitted for analysis (four samples per hundred) are submitted as field blanks, and at least one sample per hole is submitted as a field duplicate. Band-Ore also sporadically requests the re- assay of rejects at different laboratories for comparison of results. The company has retained all split core samples in the core boxes with the exception of select pieces of core and intervals taken by Band-Ore personnel for presentation purposes (which remain in the company's offices). Therefore, the author is of the opinion that the current sampling and QC/QA program now in place at Thorne meets the standards set out in NI 43-101.

MINERAL RESOURCE AND MINERAL RESERVE ESTIMATES

Band-Ore had commissioned Mr. Joe Spiteri and Spiteri Geological and Mining Consultants Inc. (SGM), in 1997-1998, to review all the drilling to date to generate a mineral resource on the company's Golden River Zones. The following are the "Methodology, Criteria and Assumptions" from the July 3rd 1997 SGM report that were used by Spiteri for his mineral resource estimations. Band-Ore has no completed any additional drilling in the area of these resources so this report will not change the Spiteri estimations discussed in the June 30, 2002 OreQuest report. The following disclosure is a summary of the Spiteri work as described in detail in the June 2002 report.

The inferred mineral resource estimate on the Golden River Zones was calculated by Joe Spiteri, in July 1997 based on the extensive Band-Ore drilling. The author believes the Spiteri estimation to be accurate and accepts the validity of the figures derived from the work completed by Spiteri. One of the purposes of this report is to recommend other areas of the property with the potential to discover additional mineralized bodies of similar or better grade and not to recalculate the resource figures generated by Spiteri. This report will not be recommending any additional drilling on the Golden River Zones.

The current resource estimate stands at 4,154,096 tonnes grading 3.33 g/t for a total of 13,824,385 grams gold (444,471 troy ounces) and was calculated in detail for internal purposes only. Mr. Spiteri has supplied the company with a letter dated June 28, 2002 where he has stated:

> *"In summary, the inferred resources estimated in 1997-98 on the Thorne Property totaling approximately 4 million tonnes of 3 g/t for about 400,000 contained gold ounces qualifies as a "Inferred Resource" under the Guidelines of NI 43-101"*

Mr. Spiteri has stated for reporting purposes, he recommends using the rounded figure of approximately 4 million tonnes of 3 g/t for about 400,000 contained gold ounces as the Inferred Resource for the Thorne mineralization to reflect the normal uncertainties in an Inferred Resource.

The Spiteri resource estimation was derived from a total of 13 separate zones all located with the Golden River Deformation Zone (GRDZ). A detailed tonnage and grade estimation of each zone, is contained in the June 30, 2002 OreQuest report and will not be repeated in this report.

MINERAL PROCESSING AND METALLURGICAL TESTING

Lakefield Research Limited performed a preliminary metallurgical examination on a 68 kilogram composite sample of drill core from the Thorne East Zone from holes TH-96-12, 19, 21, 22, 23, 25, 27, 30, 31, 32, 36, 37, 39, 41, 43, 45, 46, 47, 48, 51, 54 and 58. Lakefield completed gravity, cyanidation, froth flotation and pressure oxidization/cyanidation test on the composite sample. The information contained in this section is derived from a Lakefield report, titled "An Investigation of the Recovery of Gold and Silver from Northern Ontario Ore Samples, Lakefield Research" dated Feb 17, 1997. The author believes the information to be accurate and accepts the validity of the report.

In summary, gold recovery was poor as the gold particles were found to be fine grained regardless of feed size for both the gravity and cyanidation circuits. J. Spiteri P.Eng., summarizes the Lakefield report as follows:

> *"It was determined that a flotation time of 20 minutes would yield a recovery of in excess of 90% and a concentrate grade of 100g/t. pressure autoclaving was used as a means to oxidize the sulphide matrix. It yielded recoveries of 99% thereby indicating the refractory nature of the ore.*
> *It was concluded that a high grade concentrate can be produced by re-grinding and cleaning a rougher concentrate, but this concentrate would incur significant penalties as a result of the arsenic content. Lakefield recommended that studies be performed to test the possibility of reducing the arsenic content in the final concentrate. They did conclude that*

eliminating the arsenic would result in a loss of a significant proportion of the gold. It should be noted that the actual arsenic grade has not been established."

Spiteri further concluded that all future economic analysis or cut-off grade studies of the Thorne gold deposit should consider the refractory nature of the core samples selected from the Thorne East Zone. Core from the Thorne West was not sent for metallurgical testing.

ADJACENT PROPERTIES

The Wakemac property is three kilometres west of the Thorne (Figure 3 and Figure 4). Geological conditions on the Wakemac property are similar to other areas in the region that host gold mineralization. These include; the Destor-Porcupine Fault with which almost all the deposits in the area are spatially or genetically related, and ultramafic intrusions spatially related to gold rich quartz-carbonate veins. The intensely altered deformation zone associated with the Destor-Porcupine Fault, which hosts the mineralization on the Thorne property also underlies the southern portion of the Wakemac property. Gold mineralization discovered to date on the Wakemac property is generally related to strong ankerite sericite alteration, quartz ankerite veining and pyrite-arsenopyrite mineralization.

The Wakemac property has been worked intermittently since the 1930's, but most of the work was carried out by Hollinger Argus from 1981-85 and by Esso Minerals from 1985 to 1988 who concentrated on the Wakemac and Scott Shear Zones. The gold mineralization is associated with pyrite and arsenopyrite within a sheared quartz carbonate alteration zone along the Scott Shear while the Wakemac Shear contains substantial sericite with carbonate and minor gold. Cameco Corp. who in 1994 and 1995 carried out a program of linecutting, geological mapping, magnetic and IP geophysical surveys, and diamond drilling completed the most recent work on the Wakemac property. This work returned an encouraging drill intercept of 4.6 g/t Au over 1.1m in a silicified tuff in the south central portion of the property. Very little work appears to have been done at the favourable stratigraphic level defined by the new gold discovery on the Band-Ore Thorne property. Green Ice Corp. completed an exploration program in 1996 consisting of Phase I geophysics followed by Phase II diamond drilling. Green Ice did not intercept any significant gold intercepts from its 1996 drill program.

The Gowest Amalgamated/Hemlo Gold (Battle Mountain)- Cripple Creek property, adjoins the Thorne property to the west (Figure 3, Figure 4-occurrence #14, Figure 5). Previous companies have reported intersections such as 0.115 oz/ton gold over 16.0 feet and 0.16 oz/ton gold over 18.7 feet, have recently been reported (Gowest Amalgamated Resources Ltd., March 1996). Hemlo Gold (Battle Mountain) completed several drill programs from1993 to1996. There were multiple targets tested including the Mahoney Zone, Cripple Creek Zone 16 and Cripple Creek Zone 17. Gold occurs in a succession of ultramafic rocks intercalated with mafic metavolcanics (Mahoney Zone). Gold values of 5.77 g/t over 2.8 m, 2.68 g/t over 1.35m and 1.07 g/t over 5.0m were returned. The Cripple Creek Zone 16 and Cripple Creek Zone 17 were both drilled to test IP chargeability anomalies. The 17 Zone lies at the contact between mafic volcanics and ultramafics and returned gold values of 3.51 g/t over 5.7m, 4.40 g/t over 7.0m and 6.32 g/t over 2.2m. The 16 Zone is described as a series of altered mafic volcanic bands within a carbonatized ultramafic horizon. Gold values intercepted include 1.03 g/t over 58.0m including 11.85 g/t over 1.3m, 3.48 g/t over 14.5m and 4.7 g/t over 3.8m. The author is unaware of any current exploration being conducted on the Gowest property.

The property was acquired by Richmont Mines of Quebec in mid 2003 and exploration programs are in the planning stages.

The Thunder Creek property to the north west of the Thorne property is underlain by rock sequences that hosts the majority of the deposits in this area. Geologically, there are similarities between the mineralized quartz-feldspar porphyries on the Thunder Creek property and the Pearl Lake Porphyry, which hosts the McIntyre gold-copper deposit at Timmins, 15 kilometres to the east. Ultramafic intrusions are also present on the properties. Many of the gold deposits along the Destor-Porcupine Fault occur in quartz-carbonate veins associated with ultramafics. The Rusk showing occurs on the Band-Ore Thunder Creek property (now a part of the Thorne property). Mineralization occurs in a pyritic syenite at the contact of andesite and ultramafic intrusive. Values by various operators from trenching are up to 0.71 oz/ton gold over 4 feet, drill intersections were up to 0.099 oz/ton gold over 1.5 metres.

In 1995, Hemlo Gold optioned the Thunder Creek property and completed a humus geochemical survey, further IP surveys plus seven diamond drill holes. The humus survey outlined several areas of anomalous gold trends following the trend of the property geology. The I.P. survey, completed on selected lines, was designed to refine target locations for the drill holes. A total of seven drill holes (1,583m) was completed but did not intersect any encouraging gold values. Unaltered to weakly altered mafic volcanic flows were the dominant lithology intersected in all the holes although holes MC95-2 and MC95-7 did intersect the favourable mafic-ultramafic contact. The best alteration was located in hole MC95-4 which cut through intervals, up to 3.0 ft wide, of silicified and bleached flows hosting 3% pyrite mineralization but negligible gold values. Hemlo (now Battle Mountain Gold) continued exploration during 1996 and 1997. The 1996 exploration consisted of magnetometer surveys, IP surveys, geological surveys and a nine hole (1959m) diamond drill program. Numerous IP anomalies were detected, subsequent drilling determined that hematization, sericitization, carbonatization, sulphidization and local graphitic argillites explained most of the anomalies. The gold values intersected by the drilling were generally low, very few intervals returned values greater than 1.0/g/t Au. In 1997, an IP survey and 12 diamond drill holes (3,033m) were completed. The highest assays were 5.9 g/t Au over 1.0m (hole MC97-20), other holes generally returned weak values with gold grades of up to 1.6 g/t over widths up to 1.5m. The property was returned to Band-Ore in 1998. In November 2003 Lakeshore gold optioned the right to earn a 60% interest in 54 claims units of the Thunder Creek property. They must spend $1.7 million on exploration to earn their interest over five years. A diamond drilling program started in late November.

Black Pearl Minerals acquired ground along the south-eastern Thorne claim (Figure 3, Figure 4-occurrence #16, Figure 5). The property contains the old Thibault shaft that was the focus of limited underground development (approximately 40 feet) and diamond drilling between 1938-1946. Geology is reported to consist of a gold bearing sericite-carbonate shear zone. Mineralization consists of narrow scattered pyrite galena in a quartz vein hosted in greywackes, conglomerates in contact with a quartz feldspar porphyry. It is not clear what, if any, work was completed by Black Pearl on the Thibault shaft area. In 1996, Black Pearl drilled 29 drill holes testing IP chargeability targets combined with favourable stratigraphy. Black Pearl announced the results from a drill hole which was reported to have intersected sericitic, ankeritic, hematitized, and silicified metasediments thought to be the easterly extension of the Band-Ore Horizon mineralization (Figure 6). Hole BKP-

T-8 returned a value of 0.173 oz/ton (5.9 g/t) gold over 4.9 ft. (1.5m) A second zone drilled returned anomalous gold values within ultramafic rocks. The author is unaware of any current exploration being conducted on the Black Pearl property.

Teck Exploration optioned the Bristol Lake property in 1996. Past work has included geological mapping, geophysical surveys and diamond drilling in several locations. In 1984-85, Utah Mines sampled a showing on east side of Bristol Lake which returned 0.238 oz/ton gold from a quartz-tourmaline vein in a sheared quartz feldspar porphyry. In 1986-88, Cominco drilled six holes at the eastern end of the property, the holes intersected typical lithologies, i.e. mafic volcanics, sediments and quartz feldspar porphyries with some anomalous gold values such as 0.026, 0.10 and 0.064 oz/ton gold over three 1.5 metre intervals. In 1989, Chevron Minerals completed one diamond drill hole in south-east corner of property, which hit quartz porphyry and sediments, with the highest assay being, 115 ppb gold. Teck completed a three hole, 833meter diamond drill program on the property in the fall of 1996. The drilling did not detect any gold values greater than 1.0 g/t so the property was returned to Band-Ore but are not a part of the claims that are the subject of this report. The property was acquired by Tom Exploration in May 2006.

The Holmer Gold Mine, located close to the northern border of the Thorne property (Figure 3, Figure 4-occurrence #12, Figure 5). Holmer completed an 89 hole drill program in 1996-1998. The company has outlined indicated resources of 484,000 tons of 0.41 oz/ton gold and an inferred resource of 917,000 tons of 0.19 oz/ton gold. Included in those calculations according to Holmer is a higher-grade component of 176,000 tonnes of 28.17 g/t gold which forms part of a potential open pit resource of 720,000 tonnes of 2.57 g/t gold. The author is not aware if these resources are calculated to the standards outlined in NI43-101, all figures have been obtained from the Holmer Gold's 2001 Annual Report. **The mineralization outlined by Holmer is not necessarily indicative of the mineralization on the Thorne property**. Gold mineralization is reported to be localized within a 200 meter wide altered and deformed zone called the Holmer Fault Zone that the company believes is the western extension of the Destor-Porcupine Fault Zone. Gold is reported to lie in five distinct parallel zones that are open at depth. Holmer has also discovered a new style of mineralization locally named the Ultramafic Zone. Diamond drilling in 1997 intersected gold mineralization hosted within an ultramafic body stratigraphically below the mafic volcanics that host the other gold deposit. Holmer has reported that five widely spaced drill holes encountered several zones of mineralization between the depths of 550-800m (down-hole). Gold values returned included 3.05m/6.4 g/t, 3.72m/9.29 g/t, 2.5m/10.02 g/t, 2.27m/19.97 g/t and 9.06m/7.2 g/t (Holmer Gold's 2001 Annual Report). Holmer has recently announced that they have commenced a 13,000 foot diamond drill program to test both the near-surface target and to also test the deeper Ultramafic Zone (Holmer News Release May 27, 2002).

In May 2003 Holmer announced that Lake Shore Gold Corp optioned the right to earn a 50% interest in the property. Among other things Lake Shore must provide a report to Holmer showing the property contains an indicated mineral resource of at least 500,000 ounces of gold. Drilling commenced in June 2003. To the north of the Thunder Creek property and adjacent to Holmer and west of Tom Explorations property, Probe Mines Limited has acquired a 100% interest in 27 claim units in Bristol Township. Probe will be conducting a geophysical survey to identify drill targets.

Placer Dome has worked on its Bristol Township property from 1984-1988 completing approximately 80 diamond drill holes. The property lies less than two kilometres north of the Thorne property (Figure 3, Figure 4- occurrence #15, Figure 5). Drill results outlined zones of chloritized, sericitized, silicified, hematized quartz-feldspar porphyry over an area of approximately two kilometers by one kilometer. Erratic results of up to 10,000 ppb gold were reported. Government geologists have concluded that the Placer Dome core bears many similarities to the host rock of the McIntyre copper-gold deposit. The author is unaware of any current exploration being conducted on the Placer Dome - Bristol property. Tom Exploration Inc acquired the property in May 2003 and will be conducting a 3D interpretative induced-polarization survey to the property to help define drill targets.

There is no other "Relevant Data or Information" needed to make this technical report understandable.

INTERPRETATION AND CONCLUSIONS

The Thorne Property of Band-Ore Resources Ltd is located in the Timmins area of north-eastern Ontario. The property lies on a segment of the Destor-Porcupine Fault with which most of the gold deposits in the Timmins area are at least spatially related. There are a number of gold deposits and showings in the area and on the Thorne property including the Kapika Zone and the Golden River Zones, the Red Porphyry Zone, The Thibault Horizon and the Keno Zone.. The gold mineralization occurs in highly carbonatized sericitized sulphide bearing zones north of the Destor-Porcupine Fault a similar setting to the productive Timmins area gold mines to the east of the Thorne property.

The Thorne property has been worked intermittently since 1937; much of that work concentrated on the Kapika Zone where Esso estimated a drill indicated reserve of 292,228 tons grading 0.072 oz/ton (2.453 g/t) gold (not to NI 43-101 standards of resource definition). The Band-Ore property contains two distinct types of gold mineralization although both styles exhibit a strong spatial relationship to quartz-feldspar porphyry bodies. The Kapika Zone style of mineralization can be summarized as containing two distinct gold zones, one hosted by a red magnetite bearing porphyry and the other within arsenopyrite-pyrite-quartz-ankerite veined sericitic metasediments. The second type and the one which appears to be contain the most economic potential lies within the Band-Ore Horizon which consists of approximately 150 meter wide, strongly foliated sericite-chlorite (+/- ankerite) altered metasediments. Gold mineralization is hosted within arsenopyrite-pyrite-ankerite-quartz veins and appears to be strongest proximal to porphyry contacts although some mineralization occurs within sericitic and carbonate altered pyritic porphyries. To date, approximately 93 kilometers of drilling have been completed in 333 holes on the Band-Ore Horizon between Jan 16, 1996 and Dec 7, 1997. An additional 63 holes (13,725.8 meters) were drilled on the Kapika Zone by both Esso and Band-Ore. In 2003, Band-Ore drilled an addition 56 holes totalling 10,535.5 metres.

In 1998, Band-Ore had commissioned Mr. Joe Spiteri and Spiteri Geological and Mining Consultants Inc. to review all the drilling to date to generate a mineral resource on the company's Golden River Zones. All of the 13 zones that collectively comprise the Golden River Zones, that in turn constitute the Spiteri resource estimate, are hosted within the 750m wide Golden

River Deformation Zone. This report will not be recommending any additional drilling on the Golden River Zones at this time. Mr Spiteri states that:

> *"the inferred resources estimated in 1997-98 on the Thorne Property totaling approximately 4 million tonnes of 3 g/t for about 400,000 contained gold ounces qualifies as a "Inferred Resource" under the Guidelines of NI 43-101.*

Extensive overburden coverage means outcrop exposure is limited so that geophysical exploration methods are required for any planned future exploration. In part, electromagnetic methods are favoured but IP is now recognised as the most suitable method because the gold mineralization is associated with disseminated arsenopyrite and pyrite. The IP coverage completed by Band-Ore in 1995 and 1996 over the southern portion of the Thorne property includes all the chargeability anomalies. Since 1996, a considerable amount of diamond drilling (approximately 117 kilometers) has been performed on the Thorne property, the majority of which was conducted along Golden River Deformation Zone. Very little of the drilling has been conducted in the area south of the Golden River Deformation Zone and north of the Destor – Porcupine Fault (DPF). The geology in this area is poorly understood due to lack of outcrop, and drill hole data.

The 2003 drilling program resulted in the discovery of four new gold bearing zones termed the: "No. 14 Zone", the "Red Porphyry Zone", the "Thibault Horizon" and the "Keno Zone. The style of gold mineralization of the "No.14 Zone" is similar to the gold mineralization that occurs in the main Golden River Zones. Gold mineralization occurs in strongly deformed, strongly altered (sericite, ankerite) sediments, variable mineralized with pyrite and arsenopyrite. The gold mineralization appears to have a spatial relationship to porphyry sills that have also been intensely altered. Results returned a gold value of 9.59 g/t Au over a core length of 4.5 metres (GW-03-17), including 14.9 g/t Au over a core length of 2.7 metres. In addition, hole GW-03-29 returned a gold intersection of 3.11 g/t Au over a core length of 9.1 metres, including 4.74 g/t Au over a core length of 3.8m.

Results in the other zones were encouraging although not as high as from the No. 14 zone. Generally, broad zones of alteration with weakly anomalous gold values were intercepted and the zone has not fully been tested. Further drilling is warranted on the # 14 zone, the Thibault Horizon, the Red Porphyry zone, and the Keno Zone. Further work on all of these untested primary IP anomalies, which now appear to lie in the favourable geological target north of the DPZ, is warranted. The original work completed by Band-Ore from 1995-1998 has met the companies objectives and as outlined a mineral resource of approximately 400,000 ounces of gold (Spiteri 2002). Further targeting other areas of the property with the potential to discover additional mineralized bodies of similar or better grade is recommended.

RECOMMENDATIONS

The company has completed extensive exploration programs on the Thorne property since 1993. Numerous phases of work have been completed by Band-Ore since 1995 until 1998 including both Phase I and Phase II as recommended in the June 30, 2003 OreQuest report. Those programs were successful and met the objectives set out in the recommendations contained in that report. Based on the successful completion of Phase I and II, a Phase III program of further drilling is recommended. The cost of the Phase III program is estimated at $1,650,000. The proposed program

should consist of 50,000 feet (approximately 15,200m) of diamond drilling follow-up the successes from the drilling completed in 2003. Thick overburden hampers any other type of exploration. Particular emphasis should be focussed towards drilling more holes in the No.14 Zone. Other targets, including IP Zones developed in the previous work programs, should also be drilled. Additional work beyond Phase III, is contingent upon success in Phase III.

Dated at Vancouver, British Columbia, this 20th day of December, 2003.

/s/"George Cavey"
George Cavey, P.Geo.

COST ESTIMATE

PHASE III

Diamond Drilling 50,000 feet @ $25/foot	$1,250,000
Wages - Geologist and Assistant	84,000
Sample Analysis – 1000 samples @ $15/sample	15,000
Support Costs - all-inclusive, including meals, travel, mob/demob. etc.	70,000
report Preparation, Drafting	18,000
Contingency @ 15%	$ 212,850
Total Phase III	**$ 1,649,850**
Total Phase III (Say)	**$ 1,650,000**

CERTIFICATE OF QUALIFICATIONS

I, George Cavey, of 306-595 Howe Street, Vancouver British Columbia, hereby certify:

1. I am a graduate of the University of British Columbia (1976) and hold a B.Sc. degree in geology.
2. I am presently employed as a consulting geologist with OreQuest Consultants Ltd. of #306-595 Howe Street, Vancouver, British Columbia.
3. I have been employed in my profession by various mining companies since graduation, with OreQuest Consultants Ltd. since 1982.
4. I am a member of the Association of Professional Engineers and Geoscientists of British Columbia, and have been a member since 1992. I am also a member of the Association of Professional Engineers, Geologists and Geophysicists of Alberta, the Association of Professional Engineers and Geoscientists of Manitoba and the Association of Professional Engineers and Geoscientists of Ontario.
5. I have read the definitions of "Qualified Person" set out in NI 43-101 and certify that by reason of my education, affiliation with a professional association (as defined in NI 43-101) and past relevant work experience, I fulfil the requirements to be a "Qualified Person" for the purposes of NI 43-101.
6. I am responsible for preparation of all sections of this report utilizing data summarized in the References section of this report. The sections discussing the Mineral Processing and Metallurgical Testing as well as the section discussing Mineral Resources and Mineral Reserve Estimation were generated from specific reports referenced in those particular sections. The author had no involvement in the calculation of the Mineral Resources or in the results of the Metallurgical Testing.
7. I most recently visited the subject property on June 23rd, 2003.
8. I have had no direct involvement with the Band-Ore, Thorne property since I authored other reports for Band-Ore on the same subject property,
9. I have been the author or co-author of nine technical reports dedicated to exploration in the Band-Ore Thorne area including five reports written for Band-Ore Resources between 1993 and 2003 on the properties in the area, the most recent report prepared on the subject property was dated June 30, 2002.
10. I am not aware of any material fact or material change with respect to the subject matter of the technical report that is not reflected in the technical report, the omission to disclose which makes the technical report misleading.
11. I am independent of Band-Ore Resources Ltd. applying all the tests in Section 1.5 of NI 43-101.
12. I have read NI 43-101 and NI 43-101F1 and the technical report has been prepared in compliance with that instrument and form.
13. I consent to the use of this report for the purpose of complying with the requirements set out in NI 43-101 for completing a Band-Ore Resources Ltd. private placement financing.

DRILL HOLE RECORD

Northing:	5353228	Drill Hole:	GS-03-7
Easting:	460200		
Elevation:	1000	Claim:	1189554
		Property Name:	Thorne
Collar Azi.:	180.0	Core Size:	BQ
Collar Dip:	-45.0	Stored at:	Timmins
		Materials left:	Casing
Hole Length:	284		
Grid Co-ords:	225N/200E		
Property:	Thorneloe		
Drilled by:	Norex Drilling Ltd.		
Date Started:	12 May 2003		
Date Finished:	14 May 2003		
Date Logged:	14 May 2003		
Logged by:	R. Duess		
Purpose:	To test I.P. Anomaly

From (m)	To (m)	Geology	Sample	From (m)	To (m)	Lngth (m)	AU G/T	AU2 G/T	AS PPM
.00	19.00	OVERBURDEN							
19.00	24.40	MAFIC TUFF Medium grey to green, fine grained, chloritic tuff with interbedded sections of grey to pink (weakly hematized) greywacke. 5% finely interlaminated quartz carbonate. Fabric at 70 degrees to core axis. Trace pyrite. Non magnetic.							
24.40	26.90	GREY PORPHYRY							

From (m)	To (m)	Geology	Sample	From (m)	To (m)	Lngth (m)	AU G/T	AU2 G/T	AS PPM
		Light grey, weakly sericite altered, relatively massive. Odd speck of pyrite.	54929	24.40	25.70	1.30	.036		3
			54930	25.70	26.90	1.20	.009		2
26.90	50.00	MAFIC TUFF Same as 19.0m to 24.4m. Negligible mineralization - alteration, except as noted.							
50.00	51.30	GREY PORPHYRY White to light grey, massive, weakly altered. Remnant quartz phenocrysts. Odd speck of fuchsite, and occasional fine stringer of tourmaline. Odd speck of pyrite. Sharp contacts at 70 degrees to core axis.	54931	50.00	51.30	1.30	.013		1
51.30	89.60	MAFIC TUFF Same as 19.0 to 24.4. Occasional stretched lapilli sized clasts. Fabric at 70 degrees to core axis. Trace pyrite.	54933	72.50	74.00	1.50	nil		2
		67.50 68.50 Brown, limonite stained section. With some broken and blocky core.							
		72.50 74.00 Representative sample.							
89.60	90.20	QUARTZ FELDSPAR PORPHYRY Grey to pink, massive. Numerous white `ghost' phenocrysts in a fine grained siliceous matrix. Odd speck of pyrite. Sharp contact at 70 degrees to core axis.	54934	89.60	90.20	.60	nil		1
90.20	110.00	MAFIC TUFF Typical, chloritic, medium grey - green, fine	54935	93.20	94.70	1.50	nil		1

From (m)	To (m)	Geology	Sample	From (m)	To (m)	Lngth (m)	AU G/T	AU2 G/T	AS PPM
		grained. Non magnetic. Well foliated with fabric at 70 degrees to core axis. Non magnetic.	54936	100.00	101.00	1.00	.010		nil
		93.20 94.70 Representative sample.							
		100.40 100.70 Sericite altered section with occasional wisps of fuchsite. Trace pyrite.							
110.00	120.70	LITHIC ARENITE							
		Medium to light grey, fine to medium grained arenaceous sediment with some interbeds of dark green, chloritic tuff, and fine grained greywacke. `Grainy texture'. Gradational upper contact. Trace pyrite. Non magnetic. Local weak sericite alteration. Fabric at 70 to 75 degrees to core axis.	54937	112.30	113.30	1.00	.010		3
		112.30 113.20 Moderate sericite alteration with up to 1/2 % disseminated pyrite. 5% quartz carbonate veining.							
120.70	122.00	FELDSPAR PORPHYRY							
		Numerous, fine (2 - 3 mm) white feldspar phenos in a fine grained, dark grey matrix. Sharp contacts at 70 degrees to core axis. Non magnetic, Trace pyrite.	54938	120.70	122.00	1.30	nil		nil
122.00	137.40	LITHIC ARENITE HEMATIZED							
		Similar to 110.0 120.7. Weakly silicified. Mostly medium to light grey in colour with occasional pink to red (hematized) sections.	54939	122.00	123.50	1.50	nil		6
			54940	127.80	128.80	1.00	.150		1
			54941	132.00	133.50	1.50	.040		nil
			54942	133.50	134.50	1.00	nil		1

From (m)	To (m)	Geology	Sample	From (m)	To (m)	Lngth (m)	AU G/T	AU2 G/T	AS PPM
		122.00 123.50 Representative sample.	54943	134.50	135.50	1.00	.010	nil	2
			54945	135.50	136.50	1.00	.030		nil
		128.20 128.40 White quartz ankerite vein with strong marginal sericite alteration. Trace pyrite.	54946	136.50	137.40	.90	.010		nil
		133.50 135.50 Gradational becoming pink to red in colour (hematized) and locally silicified, Kapika type alteration. Non magnetic. Trace pyrite.							
137.40	138.20	GREY PORPHYRY							
		Numerous white quartz phenos (3 - 5 mm) in a gibe grained, light grey to pink matrix. Odd speck of pyrite. Massive and non magnetic. Sharp contacts at 70 degrees to core axis.	54947	137.40	138.20	.80	.010		2
138.20	186.20	LITHIC ARENITE HEMATIZED							
		Same as 122.0m to 137.4m.	54948	138.20	140.00	1.80	.040		nil
			54949	146.00	148.20	2.20	nil		1
