Summary

Vedron Resources Ltd. ("Vedron") is a publicly traded junior mining company listed on the TSX Venture Exchange. The head office is based in Toronto, Ontario with a field office in South Porcupine Ontario.

The Maude Ramp project consists of 83 claim units within four townships, Beatty, Carr, Coulson and Wilkie. The property straddles the Pipestone fault a known Au productive structure. Vedron has optioned the property from Globex Mining Enterprises Inc. and is earning 50 percent interest by making the required work commitments and yearly option payments. The Maude Ramp property is located approximately 12 kilometres NE of Matheson, Ontario and is accessible by all-weather gravel roads.

The Maude Ramp area has been explored for gold since the early 1900's when gold was discovered on the property in 1915 and a shaft was sunk on the Shaft Vein. The property has historically been called the Maude Lake deposit. Overall, 1268 drill holes totaling 49,286.73 metres have been completed on the Maude Ramp property to date. Sporadic exploration continued in the intervening years till 1981 when the property came under the control of Maude Lake Gold Mines Limited. Extensive work was conducted on the Maude Ramp Property and a large exploration area over the period 1981 to 1993 by Maude Lake Gold Mines Ltd and joint venture partners culminating with the underground Exploration program testing the 5 Zone with an underground ramp development. This included; 227 surface diamond drill holes totaling 37,1091.83 metres, 92 underground drill holes totaling 5,263.58 metres, and 938 percussion drill holes totaling 4,935.02 metres. During the sinking of the ramp a new, higher grade vein was discovered, the Ramp Vein.

The property was purchased by McWatters Mines in 1993 who conducted 3 diamond drill programmes and removed the ore stockpile to be milled at their Val D'or facility. The McWatters exploration was primarily targeted at further exploration and delineation of the Ramp Vein. McWatters sold the property to Globex Resources in 2002 who subsequently optioned the property to Vedron Gold in 2004.

This report details the Vedron Gold exploration consisting of linecutting, geophysics (Induced Polarization survey) and diamond drilling of 11 holes, 1986.3 metres. Drilling was primarily directed at a potential new zone discovered by McWatters in their final drill programme in drill holes 99-03 - 15.36 gpt Au / 1.4m and 99-04 - 55.5 gpt Au / 1.4m. As well 3 holes were targeted at exploring for extensions to the Ramp Vein at step-outs from historic drill results.

The geophysical programme was successful in delineating the contact zone of cherty tuffite at the Komatiite – Basalt contact, however splay features representing auriferous zones, ie; Veins 1 through 4 and the Ramp Vein were not detected in spite of the presence of sulphides with the gold mineralization.

Results were mostly negative for both aspects of the drill programme. An assay of 15.1 grams Au per tonne over 1 metre was intersected in hole VR04-05 which represents a stepout to the west from hole 99-04. However, the other 2 holes targeted on the 99-04 zone(VR04-07 and 08) failed to intersect significant gold mineralization.

Both holes targeted on the 99-03 zone (VR04-01 and 03) failed to intersect significant gold values

Three holes were lost in the fault zone while trying to test the 99-03 and 04 zones.

The three holes targeted at the Ramp Vein extension, VR04-09, 10 and 11, failed to intersect significant gold values. One hole remained in diabase for its' entire length. The other 2 holes intersected alteration and mineralized zones similar to the known Au mineralized zones but failed to return significant gold values.

Further exploration is pending the outcome of the resource estimate. Work on the property has recently consisted of permitting for de-watering of the underground. This has involved base line environmental studies and development of a closure plan.

Introduction

The Maude Ramp Property is currently under option from Globex Mining Enterprises Inc. by Vedron Gold Inc. The Maude Ramp property consists of 83 contiguous claims in Beatty, Carr, Coulson and Wilkie townships in Northeastern Ontario (Figure 2). It occurs within the Larder Lake Mining Division, and in the Land Titles Division of Cochrane. It occurs in the Ministry of Natural Resources District of Kirkland Lake. Both mining and surface rights are held on the patented claim, covering the current open pit area, i.e. P.4521 Only mining rights are covered on the remainder of the property. Surface rights on the remainder of the property are with the crown, or remain to be negotiated on the patented lots. No annual assessment work requirements are required on the Maude Ramp patented claims.

Exploration on the Maude Ramp Property in 2004 by Vedron, consisted of grid re-establishment, IP surveying, database compilation/construction, and 1986.3 metres of diamond drilling in 11 holes. A 43-101 compliant resource estimate is in progress.

Property Description

The Ramp Project, historically known as the Maude Lake deposit, is located less than 10 km northeast of the town of Matheson, Ontario (Figure 1). The property is accessed by all weather gravel roads, which connect with Highway 101 to the south. The Ramp property is located approximately 10 km north of the Apollo gold mine (historically known as the Glimmer deposit). Except in areas of previous mining activity, the property is vegetated with poplar, spruce and locally jack pine in the elevated areas, and black spruce and tamarack in the lower, commonly swampy, portions of the property. Isolated low knolls of bedrock occur on the property, <10% overall with the remainder of the property overlain by glacial lacustrine (clay), glacial fluvial (sand and gravel) and till deposits, varying in thickness from 0 to a maximum of 36.4 metres. The average drill hole casing length is 17.2 metres. The elevation of the property ranges from 285 to 290 metres MSL.

Land Tenure

The Ramp Property is currently under option from Globex Mining Enterprises Inc. by Vedron Gold Inc. Vedron is currently earning a 50% interest in the property by meeting work commitment expenditures and paying yearly pre-defined option payments. Globex contact information is as follows:

Globex Mining Enterprises Inc.
J. Stock, President
146 – 14th Street
Rouyn-Noranda, Quebec
J9X 2J3
Telephone: (819) 797-5242

Figure 2 illustrates the location of the Ramp Property claims located in Beatty, Wilkie, Carr and Coulson townships. Table 1 lists these claims (i.e. includes claims, patented claims and leases), totaling 83 claims. The proposed advanced exploration work will concentrate on claims L4521 and L40779.

Property History

Gold was discovered on the Ramp property pre-1917. A shaft and accompanying underground development was completed between 1917 and 1919 by The Hill Gold and Premiere Gold Mining Co. Underground workings occur on 2 levels totaling 61 metres and 113 metres of lateral development. From 1940 to 1946, Argyll Gold Mines Ltd, dewatered the shaft for additional sampling and diamond drilling.

Extensive work was conducted in the Ramp Property area over the period from 1981 to 1993 by Maude Lake Gold Mines Ltd and Equinox Resources Ltd. This included; 227 surface diamond drill holes totaling 37,1091.83 metres, 92 underground drill holes totaling 5,263.58 metres, and 938 percussion drill holes totaling 4,935.02 metres.

From 1983 to 1985, mining activity consisted of excavation of overburden, percussion drilling and bulk sampling of the open pit. From 1987 to 1988, Equinox Resources Ltd drove a ramp from the base of the pit to give access to the 60m, 100m and 140m levels. Approximately 855 metres of lateral development work was completed on these levels.

Bennet (1993) completed a resource estimate for the Ramp Property, totaling 813,414 tons @ 0.24 oz/t gold. Maude Lake Gold Mines hauled the ore stock piles developed from the underground workings to the Keina gold mine, in Val d'Or, Quebec for processing and gold recovery.

Globex Mining Enterprises Inc. purchased the Ramp property from McWatters on July 30th, 2001. No further exploration work was completed by Globex.

In March of 2004, Vedron Gold Inc. signed a joint venture agreement with Globex to earn a 50% interest in the Ramp Property. Grid re-establishment, followed by IP surveys were completed in the deposit area by Remy Belanger. Vedron completed 11 diamond drill holes totaling 1986.3 metres in 2004. Vedron is in the process of completing a 43-101 compliant report with accompanying resource estimate for the Ramp Property.

A summary of drilling activities on the Ramp Property is listed in Table 2. Overall, 1268 drill holes totaling 49,286.73 metres have been completed on the Ramp property to date.

Regional Geology

The following is a summary of the regional geology paraphrased from McWatters 1999 drill report by F. Roy, 1999. Figure 3 illustrates the regional geology of the property.

The entire property is underlain by the Stoughton-Roquemaure Group which is composed of essentially mafic to ultramafic volcanics with some rhyolitic centers (also referred to as the Kidd-Munro assemblage). This volcanic group is bounded by the younger Porcupine pelagic meta-sediments to the south. Faulting has been observed along this contact. Further south, the Destor –Porcupine Fault Zone makes the contact between the Porcupine and / or Stoughton-Roquemaure Group and the mafic volcanics of the Blake River Group to the south. A thin band of high energy sediments follow the trace of the Destor –Porcupine Fault Zone, namely the Timiskaming Group. Igneous rocks reported to intrude the supracrustal succession include synvolcanic layered gabbro stocks and sills; later calc-alkalic to alkalic dykes and stocks of Timiskaming age; north striking Proterozoic diabase dykes of the Matachewan swarm; lamprophyre dykes and northeastern striking Keweenawan oliving diabase dykes. Several phases of folding has been documented in the Timmins area, affecting all pre-Proterozoic lithologies. The main structural features of the area are the Destor –Porcupine Fault Zone traced W to E from Timmins to east of Duparquet where it horse-tails in several shear zones and a subparallel structure known as the Pipestone fault. {Some controversy in the interpretation of the position of this fault occurs in the literature.} Most of the gold production in the area comes from "lode gold deposits" {proximal to} these structures. Other auriferous structures in the Matheson area are well known NE to N-S fractures that host several high grade veins, the most famous being those from the Croesus mine in Munro Twp.

Property Geology

The orebodies are confined to steeply north dipping and facing mafic thoeiitic flows that occur in the stratigraphic footwall to komatiitic volcanics. A sulphide bearing sedimentary horizon, commonly with associated nodular pyrite, marks the contact between these two dominant lithologies. Feldspar and quartz feldspar porphyry dykes intrude the above lithologies. A regional NW-SE fault follows the komatiiitc / mafic contact, and is commonly referred in the property literature as the Pipestone Fault. Figure 3 illustrates the generalized Ramp property geology. Figure 4 illustrates the mine area geology with the surface projection of the mineralized zones outlined.

The economic mineralization occurs in 1) quartz carbonate vein swarm(s) that strike east-west and 2) as northeast striking quartz veins. Both are sub-vertical, the first type making up most of the geological and mineable resources to date. The vein swarm is up to 30m wide, with a maximum of 150m in strike length, open down dip below -500m. This zone is totally hosted by weakly carbonatized mafic flows, while the northeast veins have no associated alteration in the wallrocks. Up to 5% sulphides are present in both styles of mineralization.

EXPLORATION

Exploration on the Maude Ramp Property in 2004 by Vedron, consisted of linecutting or grid re-establishment, IP surveying, database compilation/construction, and 1986.3 metres of diamond drilling in 11 holes.

Linecutting was contracted to Georgex Exploration of Timmins, Ontario. The Maude Lake grid was re-established, 16.775 kilometers of line were cut including baselines and tielines. All linecutting was conducted on the pit claim overlying the established gold zones. The main purpose of the linecutting was to establish the survey fabric on the ground to facilitate spotting diamond drill holes and to complete IP coverage of the claim covering the gold occurrences.

A programme of IP was conducted over the grid that was re-established over the 5 Zone and Ramp Vein mineralized zones. IP surveying was conducted by Remi Belanger of Rouyn, Quebec.

A small team comprised of contract personnel managed these activities while based on site, and later at the Vedron exploration office in Timmins, Ontario. Team members included:

Maude Ramp Field work:	
Project Geologist(Consultant):	R. Blair Needham
Technician (Contract):	Gary Darling
Senior Geologist(Consultant)	Ken Guy

Toronto:	
President	Tom Merridith
Senior Geologist(Consultant)	Ken Guy

Analytical work was completed by Expert Laboratories in Rouyn-Noranda, Quebec. Check assays were completed by Boulamaque Laboratories, Rouyn-Noranda. IP surveying was subcontracted to Remi Belanger. Grid re-establishment was sub-contracted to Georgex Exploration Services. Diamond drilling was completed by Norex Drilling Ltd

Linecutting

Linecutting was contracted to Georgex Exploration of Timmins, Ontario. The Maude Lake grid was re-established, 16.775 kilometers of line were cut including baselines and tielines.

The base line and the 550 South tie line were established at an orientation of az 130 / 310. Section lines were established at 50 metre intervals from Line 100 West to Line 1000 West. See the DDH location plan – MAP 1

Linecutting was mostly conducted on the pit claim overlying the established gold zones. The main purpose of the linecutting was to establish the survey fabric on the ground to facilitate spotting diamond drill holes and to complete IP coverage of the claim covering the gold occurrences.

Geophysics

Geophysical surveys consisted of induced polarization surveys conducted on the grid that was re-established by Vedron.

Survey parameters were as follows:
Dipole-Dipole
Phase
'a' spacing of 25 metres
n = 1 through 6 were read
25 metre spaced stations
Phoenix Turbo V-5 IP receiver

Resistivity and Phase components were plotted at a 1:5000 scale as stacked profiles on the accompanying plans included in the back pocket.

Interpretation

Resistivity: The large broad amplitude anomaly trending through the centre of the grid at 100 south represents the Komatite unit. The other resistivity features to the south may represent silicified sections or diabase dikes that are very common and cut through the property at a bearing of north to northwest.

Phase: The large sharp amplitude anomaly trending through the centre of the grid at 350 south represents the chert-pyrite exhalite unit on the Komatite contact. The mineralized gold zones are splay features off of this exhalite. A few splays are detectible as weak phase anomaly splays off of this strong feature and probably represent the gold zones their appear to be at similar locations, however the splays do not seem to have a strike length of that larger than has been delineated by the drilling. The hope of extending the strike length of the zones through the diabases with the use of the IP does not appear to have been successful.

The weak phase feature trending from L400 West / 650 South to L1000 West / 1200 South does not appear to have been tested. This feature appears to have a corresponding Resistivity high and therefore represents a classic favourable IP feature for gold ie: chargeability and Resistivity high.

Diamond Drilling

The following describe the procedures, and results from the 2004 Maude Ramp drill program. Eleven drill holes were completed, totalling 1986.3 metres. Drilling was contracted to Norex Drilling Ltd., Porcupine, Ontario.

All 2004 drill holes were spotted in the field relative to the grid. The grid was re-established by Vedron Resources in 2004. The collar azimuth orientations were established relative to the grid. Two fore sites were used to orient the drill.

All 2004 drill holes were marked with a 2x2" stake, and labelled with an inscribed aluminium tape.

Drilling was primarily directed at a potential new zone discovered by McWatters in their final drill programme in drill holes 99-03 - 15.36 gpt Au / 1.4m and 99-04 - 55.5 gpt Au / 1.4m.

Down Hole Survey Procedures

Down hole orientation tests were conducted by the drilling crews, at approximately 50 m intervals, using a digital magnetic based system called EZ-shot by Reflex Instruments. This instrument measures digitally, hole inclination, azimuth, magnetic susceptibility, hole temperature and tool rotation. The EZ-shot system was the primary downhole survey method. The EZ-shot test notes have been filed with the drill logs in individual files for each hole.

The validity of any given reading was determined by the magnitude of the magnetic susceptibility reading. Invalid or suspect readings were not incorporated into the drill hole database

Drill Core Logging Procedures

Core was delivered to the core shack by the drillers at least once per day, commonly twice per day. The following procedures were used in the process of logging the core:

1) All core boxes were measured and labeled with aluminum tags. Forms were completed noting the down hole lengths of core, each core box held. These completed forms are included in the file folder made for each drill hole.

2) A quick log of the major units, significant alteration/mineralized zones was completed immediately as the core was brought into the core shack. This

information was then plotted on the section to record the drill holes progression.

3) The core was re-oriented in the core boxes to have bedding consistently in the same direction.
4) Detailed descriptions of the core were inputted by the geologist into a Microsoft Excel spreadsheet file directly into a laptop in the core shack. Data recorded for each hole in worksheets included the following:
   a. Drill data – claim information, start / completed dates, casing information.
   b. Collar data – Hole location and starting inclination and azimuth data
   c. Survey data – down hole survey data, depth, dip and azimuth readings
   d. Major Unit – Major unit intervals and descriptions including fields for alteration/ mineralization type and percentages, vein type, percentages and orientation.
   e. Minor Unit – Minor unit intervals and descriptions including fields for alteration/ mineralization type and percentages, vein type, percentages and orientation.
   f. Point data – Systematic core angle measurements of specific features such as unit contacts, foliation, bedding and vein orientations
   g. Sample data – Individual sample descriptions including fields for alteration/ mineralization type and percentages, vein type, percentages and orientation.
   h. Assay data – Assay Laboratory text files were compiled into a separate Excel spreadsheet then incorporated into the drill hole sample data worksheet.
   i. Geotech1 data – Data was completed by the geological technician who recorded the core recovery and RQD on 3 metre intervals (i.e. between metreage blocks) onto specific forms made for recording this data. The data was subsequently inputted into the Geotech1 Excel worksheet for each drill hole and the core recovery and RQD was calculated from the data recorded.
   j. Photos – Records the file names of the systematic digital photographs taken in the logging procedure.
5) Selected fields from the Excel table were exported to text files which were subsequently imported into the Vedron Gemcom drill hole and resource estimation database program.
6) The drill core, usually 4 boxes at a time, was then placed on an inclined bench and digitally photographed dry and wet.
7) The core was then sampled, as defined by the logging geologist using a Longyear wheel type splitter. Care was taken to consistently put the same portion of core in the sample bag and the other half back into the core box. Assay laboratory tags were placed and/or stapled into the core box at the beginning of each sample.
8) Once the core was logged and sampled, the core was moved outside and cross piled on 5 x 5 foot wooden pallets. Note that significant zones of mineralization were set aside for further review/re-sampling.

The drill core was logged by the field geologist (R. Blair Needham). Rock codes used were established using the Vedron geological legend, Table 3.

2004 Maude Ramp exploration program geological core logs were completed in the Vedron office, by importing data from the Excel spreadsheets to a program called Geotic. These logs are included as Appendix 1.

2003 Drill Program Results

The following outlines the results of the drilling activities completed in the 2004 Maude Ramp drill program.

Table 1 is a summary of the results of the drill program.
The drillhole locations are shown on the drillhole plan Map 1 in the back pocket
Sections of the drillholes are Maps 2 through 7 in the back pocket
The geological legend for the sections is given as table 3
Diamond drill logs are given in Appendix 1

Drilling was primarily directed at a potential new zone discovered by McWatters in their final drill programme in drill holes 99-03 - 15.36 gpt Au / 1.4m and 99-04 - 55.5 gpt Au / 1.4m.

Holes VR04-1,2 and 3 were targeted at testing around hole 99-03 - 15.36 gpt Au / 1.4m, to both the east and west. Holes 01 and 03 intersected altered basalt with mineralization, however gold values were low. Hole 2 was lost in a fault zone in basalt at 208 metres but had intersected alteration with mineralization that resulted in the best assay of the test of 99-03 with a result of 1.01 grams Au per tonne over 2.75 metres

Holes VR04-4 through 8 were targeted at 99-04 - 55.5 gpt Au / 1.4m to again test for extensions to the east and west. Two holes 04 and 06 were lost at shallow depths in a fault zone in the Komatiites. Hole 05 was drilled to the west of 99-04 and intersected mineralized and altered basalt with one section containing visible gold and assaying 15.1 grams Au per tonne over 1.0 metres from 204.3 to 205.3. This zone corresponds to the zone in 99-04.

Holes VR04-9, 10 and 11 were targeted at testing for the Ramp Vein extensions in the vicinity of the previous work and the underground workings. Hole VR04-9 collared in diabase and remained in diabase for its' entire length of 140 metres, it was hoped to go through the diabase and intersect the zone, however the width of the diabase precluded the hope on intersecting the zone and therefore the hole was stopped. Holes VR04-10 and 11 both intersected favourable alteration and mineralization at expected depths to correspond to mineralized zones, however assays were low.

Note: The drillers encountered difficult ground with fault zones "squeezing" the rods in several of the drill holes.

Three holes, VR04-2, 4 and 6 were lost in the fault zone within the Komatiite unit, this fault zone caused squeezing of the rods resulting in the drill string becoming stuck and sometimes braking off.

Results were mostly negative for both aspects of the drill programme. An assay of 15.1 grams Au per tonne over 1 metre was intersected in hole VR04-05 which represents a stepout to the west from hole 99-04. However, the other 2 holes targeted on the 99-04 zone(VR04-07 and 08) failed to intersect significant gold mineralization.

Both holes targeted on the 99-03 zone (VR04-01 and 03) failed to intersect significant gold values

Three holes were lost in the fault zone while trying to test the 99-03 and 04 zones.

The three holes targeted at the Ramp Vein extension, VR04-09, 10 and 11, failed to intersect significant gold values. One hole remained in diabase for its' entire length. The other 2 holes intersected alteration and mineralized zones similar to the known Au mineralized zones but failed to return significant gold values.

Core Sampling Procedures

Any prospective sulphide, veining, or favourable alteration (such as silicification, carbonatization etc.), was measured, described and tagged for sampling by the field geologist. Assay samples were collected from core intervals ranging from no less than 0.3 metres to a maximum of 1.5 metres in length. Core lengths within strongly mineralized zones were in general limited to less than 1.0 metre. This core was split down the long axis of the core by a technician using a Longyear wheel splitter. One half of the core was returned to the core box, and the other was bagged. The same half of core was always placed in the sample bag, and therefore no bias was introduced into the sample assay.

SAMPLE PREPARATION, ANALYSES AND SECURITY

Assay procedures

Every sample was fire assayed for gold (1AT - ~30g) with an atomic absorption (AA) finish. Pulps from samples, that had initial assays > 1 g/t Au, were re-assayed with a gravimetric finish. All samples greater than 10 g/t Au were re-assayed using pulp metallics sieve method, using a 150 mesh screen.

All gold assays are initially reported parts per billion(ppb), and subsequently converted to grams/tonne (g/t). This method took an a 500 g sub-sample/cut from the reject material of the sample. This material was then pulverized, and then the pulverized material was run through a 150 mesh sieve. The material collected on the sieve was weighed, and then fire assayed. A cut of the minus fraction of the sample, i.e. the material that was allowed through the sieve, was also assayed. The weighted average of each sample was then calculated to give the final gold assay result in grams/tonne.

A Vedron convention of using the initial AA finish gold assay when no other assay method was completed, and using the gravimetric result when this assay method was completed on the sample. The pulp metallic assay result replaces the gravimetric or the AA finish assay result when this method tested the sample. Thus a hierarchical system of reporting the gold assays returned was employed, starting at the AA finish, followed by gravimetric finish and finally the pulp metallic assay method. The plotting of gold results, and the calculation of composites, used the Au g/t field in the database.

The assays are given in the drill logs and plotted on the Sections.

The certified assay certificates are included as Appendix 2.

CERTIFICATE OF QUALIFICATION

This is to certify that:

I am a Consulting Geologist and reside at 330 Chambers Crescent, Newmarket, Ontario, L3X 1T2 – ph (905) 898-8092, email: kenguy@rogers.com

I am a graduate of the University of Waterloo (H.BSc. 1978).

I have worked in the mining industry as a geologist since 1978

I am a member of the Professional Geologists of Ontario, the Prospectors and Developers Association of Canada, and am a Fellow of the Geological Association of Canada since 1984.

This report on the 2004 Exploration Program of the Maude Ramp Property is consistent with my professional experience and is based on all the available data.

I have no direct or indirect interest in **Vedron Gold Inc. or Globex Mining Enterprise**, nor do I expect to obtain any.

Signed in South Porcupine, this March 16, 2006.

164.75	165.40	MZ - KT BAS bxw sils mns **Mineralized Zone - weakly to moderately brecciated basalt** Dark bronze to medium yellow green grey, mineralized basalt. Pyrite mineralization primary appearing possibly recrystallized. Overall approximately 40% pyrite. Weakly brecciated to foliated @ 52 dtca. H 5. Strongly silicified, intensely calcite altered and weakly to moderately sericitized. Pyrite mineralization strongest @ upper contact massive to semi-massive, occurring as 1-3cm seams in the lower 50cm of the unit. 10-15% discontinuous carbonate quartz chlorite fracture fills stringers subparallel to foliation. Sharp mineralization defined lower contact @ 52 dtca.										
165.40	183.75	BAS amg bxw chlw chlm cals silm **Variably calcite silica altered massive to weakly amygdaloidal Basalt** Mottled light green grey to dark green grey, variably altered massive to amygdaloidal tholeiitic basalt. Patchy moderate bleaching commonly associated with calcite sericite and or moderate to strong silicification. Altered bands commonly assocoiated with weakly to moderately brecciated horizons up to 1.5 metres wide. Blocky core from 175.25 to 178.8 metres. H 5 to 5, rare light grey aphanitic intensely silicified seam 20 cm wide. Weakly to moderately pervasively chloritized matrix with the upper 5 metres very weakly sericitized. Moderately to intensely calcite altered. Patchy weak to strong silicification, trace to locally 0.5 pyrite mineralized, commonly associated with bleached brecciated bands, trace to 0.3% disseminated pyrrhotite (primary mineralization?). 3-locally 10% carbonate quartz fracture fills and rare glassy quartz carbonate chlorite veinlet. Lower contact, faulting and lithology defined @ 58 dtca.

Comments

Purpose: Test east extension of Ramp vein 05 zone mineralization
Comments: Only Diabase intersected with brecciated fault zones over several intervals
Results: Diabase intersected throughout.

Core size : NQ

Cemented : Yes

Storage : Yes

DESCRIPTION			ASSAYS								
			From	To	Nmb	LENGTH	Au_Final G T	Au1a ppb	Au1b ppb	Au2a g t	Au2b g t
		Dark grey to pinkish grey to green grey, very fine grained pillowed basalt. Weakly brecciated bands up to 70 cm wide with associated calcite + - quartz fracture fills and silicified seams infilling breccia matrix. Very weak chlorite alteration associated with brecciation or rimming pillow selvages. Patchy weak, very fine grained, pervasive hematite alteration associated with pinkish grey hue horizons prevalent in down hole to approximately 73.7 metres. Downhole of 73.7 metres gradual increase in pervasive chloritization. Very fine grained light green to buff siliceous pillow selvages. Pillow selvages locally very strongly chlorite calcite impregnated. Rare tourmaline impregnated pillow selvage. Pillow selvages commonly pyrrhotite mineralized with a halo of medium grained pyrite grains. Non to weakly developed foliation @ approximately 20 to 32 dtca. Strongly blocky core, bleached, calcite altered Fault zone ? from 61.27 to 62.2 metres, breccia textures at 32 to 36 with thin pitt

Comments

Purpose: Test east extension of Ramp vein 05 zone mineralization
Comments: Broad zone of pyrrhoite and pyrite mineralization in recrystallized pillow basalt from approx. 95 to 110 metres. KT massive sulphide horizon from 110-113 metres.
Results: Mineralized zones commonly associated with brecciation and strong silicification limited veining 50.28-54.73m, 185.95-201.75m, 201.75-213.92m(wk). KT mas py horizon (relatively wk). Porphyry dykes intersected in the upper portion of the hole

Core size : NQ

Cemented : Yes

Storage : Yes

		Variably bleached, fe dolomite siliceous pillowed Basalt, transitional unit Dark grey to light green grey, fine grained, pillowed basalt. Variable bleaching associated with fe dolomite alteration (approximately 40% bleached bands). Alteration subparallel to weak foliation or variably brecciated quartz carbonate impregnated pillow margins @ 20 to 30 dtca. H 4.5- 5. Weakly to moderately silicified. Non to locally strongly bleached. fe dolomite altered. Chloritized pillow selvages, trace to locally 3% pyrite mineralization proximal to pillow selvages. Trace to locally 5% pyrrhotite fracture fills clots also associated with pillow margins. Gradual increase in sphalerite clots fracture fills downhole. 3 to 10% irregular carbonate quartz fracture fills at various angles but commonly subparallel to foliation. Lower contact gradational alteration defined.
