2 • 3 7 1 1 1

This composite photograph of the main gold-bearing intersection shows an aplite dike with its quartz-microcline? halo into the wallrock gabbro uphole, which also altered ilmenite to sphene-leucoxene. The contact is obtuse between samples 51530/84886 (530/886 on photo), or if this is a remainder of an older aplite prior to the deposition of pyrite-gold, 30-45°CA between 532/533. The gold values (in red, in g/t) correlate with <7mm pyrite cubes along fractures, often resulting in jagged veinlets. The cubes often have a <0.3mm selvage of dark quartz which limits the conductivity of the veinlets. These pyrite veinlets are crosscut by the quartz tension gashes caused by the dike at nearly right angles, and would therefore be parallel to the dike and older. They occur also in the remaining margin of that previous aplite (51532), in the same direction and also with gold values. Such a previous aplite also exists as a xenolith within the downhole margin of the dike and also has gold values.

The newer aplite with very fine disseminated pyrite and its quartz-microcline halo returned only a few anomalous values. One could therefore hypothesize that the gold-bearing pyrite had deposited in a pre-cursor fracture zone of this newer aplite dike. The few core angles of the pyrite cube veinlets present range from 45-60°CA, suggesting a true thickness of over 2m. This would better fit the aplite outcrop at L1850N - 1794E, attitude 350/70, than the one of the Highway Gold showing nearly vertically above the intersection of 320/60-80 overall. The high gold values with pyrite at the showing also occur only in a small part probably of previous aplite. Much overburden stripping is recommended especially between the known aplite dikes and between the two drill holes CP-07-7 and CP-07-8, concentrating on signs of pyrite anywhere.

The gold in CP-06-5 occurs in the same kind of cubic pyrite veinlets, there with a halo of gray quartz, in chaotic very fine-grained gabbro uphole from its contact to tonalite. The gray haloes would have been obliterated here. This confirms that gold did not depend on the alteration present here, but deposits with cubic pyrite and very minor gray quartz along fractures. The intersection in CP-06-5 is at 620m towards 205°az. from here.

Introduction

The goal of the present drilling was to test the depth extent of the Highway Gold showing, previously called the North of the Old Highway Gold showing. The intersections confirm the gold values and allow a hypothesis that should be useful in the recommended further excavation or drilling.

The Highway Gold showing is 30m north of the old highway to Kamiskotia, in Jamieson Township, 420m due East of the Robb Township Line. About 20km west of Timmins on Highway 576, 3.5km before Kamiskotia Lake, the power line follows the old highway and crosses Highway 576 just 200m East of a turnoff to the north, which is the access to the old, partly cleared highway. The Highway Gold showing is at 550m northwestward along it, at NAD83 456400E - 5377120N.

The two NQ diamond drill holes CP-07-7 and CP-07-8 totaling 412m, collared 15m NE from the road side, were sunk by MW Diamond Drilling, P.O.Box 645, Porcupine, P0N 1C0, from 30 July 2007 to 10 Aug 2007, for Claim Post Resources Inc. 1010 - 55 University Ave, Toronto, M5J 2H7. The author Hermann Daxl, M.Sc. Mineral Exploration, Tel/Fax 705-264-4929, attended to all work and logged the core, which is stored at 6076 King Street, Porcupine, Ontario. The various types of analyses were done by Swastika, Expert, Activation, and ALS Chemex, Laboratories.

Previous Work

Historic work in this area included overburden stripping, a few trenches, and a 4m deep pit, and discovered gold. Exploration work in 2004 by Pele Mountain Resources Inc. included an IP survey on L1850N and L2000E by Geoserve Inc., and clearing, mapping, and channel sampling the showing by Kian A. Jensen. This work is in the MNDM files under T-5092 and 2.28860. A copy of the map and values is attached. Gold values associated with pyrite in an aplite dike were confirmed, but must not mislead to pursue just any aplites, as the present work explains.

No detailed MAG survey was done but a general rapid magnetic increase eastward along L1850N is seen from the attached excerpt of the OGS Map 81755. A detailed MAG map would show magnetite destruction along aplite, but also along faults, other dikes, and some quartz-veins, as well as the widely variable magnetism of gabbros themselves. A detailed

MAG survey should therefore not be relied on for rock types, but could be used to approximate the depth of overburden.

In hindsight, the relatively minor IP resistivity and chargeability anomalies could be related to silicification and aplite, with its disseminated very fine pyrite, however, it is not this alteration, nor all aplite, nor such pyrite, which carry the gold here, nor in drill hole CP-06-5 where these do not exist. The general interpretation of mere outcrop or ilmenite, causing much stronger such anomalies as seen in CP-06-1 to 6, could also be applied here. The cubic pyrite veinlets with quartz selvages here are not conductive, and cannot cause any geophysical anomaly to rely on in further exploration. The mineralization can be pursued only with geological knowledge obtained through much care, from core recovery to logging to drafting.

Present Work

Two NQ diamond drill holes, CP-07-7 and CP-07-8 totaling 412m, were sunk parallel to L1850N in opposite directions, but offset by 29m. After aplite dikes in various directions were dug up, CP-07-7 was meant to intersect the shear zone that continues in the gabbro between the showing and the pit (Jensen's samples 185337 and 339). After intersecting strong quartz-microcline? alteration of gabbro, with cubic-pyrite veinlets known to have gold values, and a thick aplite dike at good core angles, and a further convoluted aplite dike in a narrow shear zone along the hole, CP-07-8 was collared to test the thickness, and a deeper level of the promising pyrite zone.

Following the detailed logging and studying of the core one can hypothesize that the gold was deposited with the cubic-pyrite veinlets (without quartz) in the margin and the wallrock of a previous aplite of which an uphole contact and a xenolith in the downhole margin of the thick younger aplite dike exist. These pyrite veinlets are crosscut at right angles by the quartz tension gashes across the aplites, and therefore are parallel to these dikes. The thickness of the gold-bearing wallrock here would be about 2m, and the thickness of the previous aplite is not known.

The younger aplite has only very minor such pyrite veinlets, consequently with only anomalous gold, and no gold is associated with the barren alteration halo attributed to it. The <7mm pyrite cubes would have been deposited along fractures preceding the intrusion of the aplite, whereas the very similar alteration maybe due to metasommatism after the intrusion. This is supported also by the same type of cubic-pyrite veinlets with gold values in CP-06-5, where there is no alteration other than a <3cm halo of gray quartz along them, which in the present area would have been obliterated. Even the very fine ilmenite survived. Also these veinlets in CP-06-5 are in the gabbro wallrock of a quite different tonalite.

This means that aplites are not better targets than other fracture systems that may have developed near contacts or elsewhere, in any rock type prone to fracturing. In the Highway Gold area the main intersection is best projected to the aplite dike at L1850N - 1794E. At the showing, the gold at mainly one spot of the aplite dike may actually be in such a previous aplite xenolith. The promising gabbro wallrock has hardly been prospected, and pyrite there may actually have been completely obliterated by weathering.

The quartz-potassium (microcline? saussurite? sericite? ankerite?) altered gabbro wallrock can hardly be told from the pale olive aplite even as drill core, except for <1mm shreds of light-brownish sphene-leucoxene after the ilmenite of the gabbro. The recommended mapping and sampling after overburden stripping of the high ground between the two drill holes will therefore need much detail work to find pyrite veinlets or their remnants regardless of rock types, rather than dikes most of which may be barren, or their halos.

In case of drilling, other directions especially due west, could be tried, but core angles of 45-60 CA of the so far only few pyrite veinlets would be acceptable. Since CP-07-8, drilled only 29m SW but parallel to CP-07-7, intersected no other indication of gold than 0.16 g/t Au / 0.15m of a somewhat ochre-oxidized quartz-microcline? vein, the next hole should be collared further northeast of CP-07-7. The several sub-parallel faults 0-25 CA in CP-07-7 may have shifted the southwest area, and there is no outcrop.

I prospected the surface within a 60m radius from the showing, from NW to E with the Beep Mat BM4+ at 5-10m intervals without success, despite the often very thin overburden. Conductivity tests on the cubic pyrite veins correlating with gold in the drill core showed that they seldom are conductive even over 3 cm due to a <0.3mm selvage of dark quartz around each cube. This would be too limited for any Beep Mat, but for the minor expense the Beep Mat M4+ should be used anyway.

The present work also includes photographs of the main gold intersection, the drill logs, the map, the section, and analyses of various types by four labs, all accompanying this report.

Geology

The Highway Gold area lies in the regional Kamiskotia Gabbroic Complex, reportedly a tholeiitic intrusive overlain by the Kamiskotia Volcanic Complex of basalt and rhyolite.

The section of the two present drill holes shows magnetic mela-gabbro in the WNW, probably younger according to a chilled contact in CP-07-7. The center is mostly fine-grained gabbro, frequently magnetic, and Ti-rich according to the frequent sphene-leucoxene alteration of ilmenite due to two aplite dikes with wide halos of very similar quartz-microcline? alteration. In the ESE between faults a gabbro is variable with oxidized magnetite-ilmenite, followed at depth by a more pristine gabbro, often magnetic or with ilmenite or both, with medium-grained gray plagioclase and minor zones of granitic xenoliths.

Gold Mineralization

The main gold-bearing intersection is shown in the attached photographs, and details of gold mineralization are described there in reference to it.

Sampling and Gold Analyses

Samples were chosen according to mineralization so that values could be attributed to features. Therefore lengths vary from 15 - 45cm, mostly near 30cm. Approximately 250g were pulverized, and in case of values 1 - 4 such pulps could be made, so any sparse particle effect could be noticed and averaged, not discarded as if wrong. 30g aliquots were used for all fire assays, but they varied between 28 - 40g in neutron-activation this time. Few such minor effects were noticed, but gold values in the xenolith of previous aplite 84894 varied between pulps as well as between aliquots of the same pulp, namely 0.55, 1.07, 2.71 g/t.

To be reasonably safe, all samples with anomalous gold, >0.03 g/t, must be pulped completely as several pulps of 250g, because low-grade sparse particle effects occur usually between pulps, and rarely within them. It is important to give the same attention to small initial values, not to dilute only the high initial values. Although no visible gold was encountered, the gold in the pyrite seems to be unevenly distributed and often quite high, namely sample 51529 averages 20.46 g/t Au, and 4.3 g/t Ag, relative to an estimated 10 weight-% pyrite as shown in the photograph.

Larger samples would require finer crushing, larger pulps, and larger aliquots. They would give less information, and lab errors would be more difficult to detect and to correct. The present assay procedures rather than metallic sieve or total pulverization should be continued.

Conclusions and Recommendations

From the present drilling, and the previous six drill holes CP-06-1 to 6 within 700m SSW across Highway 576, one may hypothesize that the gold and the aplite dikes originate from fault blocks of sedimentary rocks engulfed by the Kamiskotia Gabbro intrusion. Heat from the cooling gabbro would first have driven off water and sulfur with metals and gold,

and finally melted and injected them as tonalites and aplite dikes. The gold would have deposited on both sides of contacts to gabbro and along fracture zones in gabbro, followed by aplite dikes likely in the same weak zones. The alteration and quartz tension gashes would have been caused by the cooling dikes later. By overlap, older dikes could carry gold, but no alteration has been encountered to carry gold unless there are also pyrite cubes. It follows that the quartz-sphalerite veins and even the quartz-chalcopyrite veins south of Highway 576, both with gold values, are from the same system but deposited under different temperatures or pressures, usually more distant from the source.

The wider area of thin overburden from northwest to east of the Highway Gold showing should be prospected with the Beep Mat BM4+ as the only possibly efficient geophysical tool for this kind of mineralization. Manual and mechanical excavation should follow to locate a reliable direction for drilling the gold zone. As explained above, the target should neither be the many aplite dikes nor the very similar altered gabbro, but rather any sign of fracture zone or pyrite in any type of rock, but especially wallrock.

Respectfully submitted,

Timmins, 14 Feb 2008

JENSEN 2004, T-5092

Legend and Rock Description

(Highway Gold 2007 Drilling)

Rock Units:

Aplite	Pale olive, <1 mm grained felsic dikes, with very similar haloes (QK? alteration) but some sphene or leucoxene still visible in haloes.
B	Basalt, gray to melanocratic dark gray.
FG	Fine- to very fine-grained gabbro, usually dark gray with black specks well visible on dry core. These are ilmenite (il), subhedral, 0.5 to 1 mm, <15% disseminated, or with magnetic ilmenite likely due to intergrowth or exsolution of magnetite (mil), or
mFGil	octahedrally laminated magnetite-ilmenite, which shows when altered.
mtFGil	When ilmenite near aplite or faults is altered to sphene (sn), or to pale-buff leucoxene (lx) of same habit visible on wet core.
FGsn	Medium-grained gray gabbro, here with gray plagioclase.
FGlx	When ilmenite near aplite or faults is altered to sphene (sn), or to pale-buff leucoxene (lx) of same habit visible on wet core.
G	Medium-grained gray gabbro, here with gray plagioclase.

Structure:

350/70	Strike azimuth and right-hand dip.
F30	Fault at 30 degrees to core axis (CA), evidenced by shear, broken core, or some gouge. FZ is wider fault zone.
FZ	Quartz-microcline? (with ankerite?) as thick vein (QKV), or stockwork, or ubiquitous alteration.
QK	Veins of quartz-calcite, or QV if >15 cm thick.
qcv	Water seam, as reported by drillers, or at limonite alteration.

Main values plotted:

Au in g/t, over meters, e.g. 2.57Au / 2.79

CLAIM POST RESOURCES INC.
Kamiskotia Project - Highway Gold Area
14 Feb 2008, by Hermann Daxl, M.Sc.

Scale: 1 : 1000

This composite photograph of the main gold-bearing intersection shows an aplite dike with its quartz-microcline? halo into the wallrock gabbro uphole, which also altered ilmenite to sphene-leucoxene. The contact is obtuse between samples 51530/84886 (530/886 on photo), or if this is a remainder of an older aplite prior to the deposition of pyrite-gold, 30-45CA between 532/533. The gold values (in red, in g/t) correlate with <7mm pyrite cubes along fractures, often resulting in jagged veinlets. The cubes often have a <0.3mm selvage of dark quartz which limits the conductivity of the veinlets. These pyrite veinlets are crosscut by the quartz tension gashes caused by the dike at nearly right angles, and would therefore be parallel to the dike and older. They occur also in the remaining margin of that previous aplite (51532), in the same direction and also with gold values. Such a previous aplite also exists as a xenolith within the downhole margin of the dike and also has gold values.

The newer aplite with very fine disseminated pyrite and its quartz-microcline halo returned only a few anomalous values. One could therefore hypothesize that the gold-bearing pyrite had deposited in a pre-cursor fracture zone of this newer aplite dike. The few core angles of the pyrite cube veinlets present range from 45-60 CA, suggesting a true thickness of over 2m. This would better fit the aplite outcrop at L1850N - 1794E, attitude 350/70, than the one of the Highway Gold showing nearly vertically above the intersection of 320/60-80 overall. The high gold values with pyrite at the showing also occur only in a small part probably of previous aplite. Much overburden stripping is recommended especially between the known aplite dikes and between the two drill holes CP-07-7 and CP-07-8, concentrating on signs of pyrite anywhere.

The gold in CP-06-5 occurs in the same kind of cubic pyrite veinlets, there with a halo of gray quartz, in chaotic very fine-grained gabbro uphole from its contact to tonalite. The gray haloes would have been obliterated here. This confirms that gold did not depend on the alteration present here, but deposits with cubic pyrite and very minor gray quartz along fractures. The intersection in CP-06-5 is at 620m towards 205 az. from here.

CP-07-7

Legend and Rock Description

(Highway Gold 2007 Drilling)

Rock Units:

- Aplite Pale olive, <1mm grained felsic dikes, with very similar haloes (QK?-alteration) but some sphene or leucoxene still visible in haloes.
- B Basalt, gray to melanocratic dark gray.
- FG Fine- to very fine-grained gabbro, usually dark gray with
- FGil black specks well visible on dry core. These are ilmenite (il), subhedral, 0.5 to 1mm, <15% disseminated, or with
- mFGil magnetic ilmenite likely due to intergrowth or exsolution of magnetite (mil), or
- mtFGil octahedrally laminated magnetite-ilmenite, which shows when altered.
- FGsn When ilmenite near aplite or faults is altered to sphene (sn),
- FGlx or to pale-buff leucoxene (lx) of same habit visible on wet core.
- G Medium-grained gray gabbro, here with gray plagioclase.

Structure:

- 350/70 Strike azimuth and right-hand dip.
- F30 Fault at 30 degrees to core axis (CA), evidenced by shear,
- FZ broken core, or some gouge. FZ is wider fault zone.
- QK Quartz-microcline? (with ankerite?) as thick vein (QKV), or stockwork, or ubiquitous alteration.
- qcv Veins of quartz-calcite, or QV if >15cm thick.
- W Water seam, as reported by drillers, or at limonite alteration.

Main values plotted:

Au in g/t, over meters, e.g. 2.57Au / 2.79

4-Corners Grid (L2000E is 35 az, Mag decl. 11 W)

Grid Location (m): parallel L1815N - 1767 E

Map: G-3986 Township: JAMIESON Claims: 3010918 - 70%
UTM NAD 83 - Elevation 1m below CP-07-7 3016588 - 30%
17U 0456324 E - 5377139 N

DDH Direction (azimuth) / Dip (plunge): 125/50 degrees

Hole Length: 261 m Core Diameter: NQ - 47 mm ^{humus on}
Casing Length: 16 m Overburden Thickness: 12 m (^{dense} clay).

Casing left in hole and capped, marked by wood post, cap bolted.

Other: Can suck enough water for drilling. Used rod grease.

Core stored in 60 trays at: 6076 King St, Porcupine, Ont.

Samples (Continuous sawed half core):

51600 - 611, 84915 - 943.

Highlights:

Legend:

H Mohs' hardness, as measure of alteration.

M5 Magnetic like magnetite, M0 = nonmagnetic.

CA Degrees to core axis.

fizz Reaction to cold 10% HCl.

RQD % core length longer than 2.5 x diam, >12cm.

Analyses

BCD (2nd,3rd,4th 250g pulp), E (Expert Lab), G (Gravimetric),
N (Neutron activation), T (near-Total ICP), W (fusion, majors + 45).
Swastika Lab, Expert Lab, Actlabs (for NTW), ALS Chemex.

CERTIFICATE OF ANALYSIS

34 Core samples were submitted for analysis.

Made ~ 250 pulps

The following analytical packages were requested:

Code 1D INAA(INAAGEO)
Code 1H2 INAA(INAAGEO)/Total Digestion ICP(TOTAL)/Total
Digestion ICP/MS

REPORT A08-0020

This report may be reproduced without our consent. If only selected portions of the report are reproduced, permission must be obtained. If no instructions were given at time of sample submittal regarding excess material, it will be discarded within 90 days of this report. Our liability is limited solely to the analytical cost of these analyses. Test results are representative only of material submitted for analysis.

Notes:

Elements which exceed the upper limits should be analyzed by assay techniques. Some elements are reported by multiple techniques. These are indicated by MULT.
For values exceeding the upper limits we recommend assays.

CERTIFICATE OF ANALYSIS

14 Pulp samples and 18 Rock samples were submitted for analysis.

The following analytical packages were requested: Code 1F2 Total Digestion ICP(TOTAL)

Code 1D INAA(INAAGEO)

REPORT A08-0233 Code 4LITHO (1-10) Major Elements Fusion ICP(WRA)/Trace Elements Fusion ICP/MS(WRA4B2)

This report may be reproduced without our consent. If only selected portions of the report are reproduced, permission must be obtained. If no instructions were given at time of sample submittal regarding excess material, it will be discarded within 90 days of this report. Our liability is limited solely to the analytical cost of these analyses. Test results are representative only of material submitted for analysis.

Notes:

For values exceeding the upper limits we recommend assays.

If value exceeds upper limit we recommend re assay by fire assay gravimetric-Code 1A3

Values which exceed the upper limit should be assayed for accurate numbers.

We recommend using option 4B1 for accurate levels of the base metals Cu, Pb, Zn, Ni and Ag. Option 4B-INAA for As, Sb, high W >100ppm, Cr >1000ppm and Sn >50ppm by Code 5D.

Values for these elements provided by Fusion ICP/MS, are order of magnitude only and are provided for general information. Mineralized samples should have the Quant option selected or request assays for values which exceed the range of option 4B1. Total includes all elements in % oxide to the left of total.

Legend and Rock Description

(Highway Gold 2007 Drilling)

Rock Units:

Aplite	Pale olive, <1mm grained felsic dikes, with very similar haloes (QK?-alteration) but some sphene or leucoxene still visible in haloes.
B	Basalt, gray to melanocratic dark gray.
FG	Fine- to very fine-grained gabbro, usually dark gray with black specks well visible on dry core. These are ilmenite (il), subhedral, 0.5 to 1mm, <15% disseminated, or with
FGil	magnetic ilmenite likely due to intergrowth or exsolution of magnetite (mil), or
mtFGil	octahedrally laminated magnetite-ilmenite, which shows when altered.
FGsn	When ilmenite near aplite or faults is altered to sphene (sn),
FGlx	or to pale-buff leucoxene (lx) of same habit visible on wet core.
G	Medium-grained gray gabbro, here with gray plagioclase.

Structure:

350/70	Strike azimuth and right-hand dip.
F30	Fault at 30 degrees to core axis (CA), evidenced by shear, broken core, or some gouge. FZ is wider fault zone.
FZ	
QK	Quartz-microcline? (with ankerite?) as thick vein (QKV), or stockwork, or ubiquitous alteration.
qcv	Veins of quartz-calcite, or QV if >15cm thick.
W	Water seam, as reported by drillers, or at limonite alteration.

Main values plotted:

Au in g/t, over meters, e.g. 2.57Au / 2.79
