4-CORNERS AND HIGHWAY GOLD

Introduction

The present conventional soil samples of the enriched B-horizon were taken on occasion from October 2006 until April 2008 to find a sampling method and type of analyses that would help to locate an economic deposit of the known zinc-gold, copper-gold, or gold-only mineralizations. All work was done by the author for the holders of the claims Claim Post Resources Inc. The analyses were done by Activation Laboratories Ltd. in Ancaster, Ontario.

The 85 samples were taken from the SW corner of Jamieson township northward to Highway 576 on claims 3012747, 3012748, 3011003, and more sparsely north of Highway 576 on claim 3010918, including 10 background samples outside. The area is 20km northwest of Timmins via Highway 576, three km before the Kamiskotia Lake. Please refer to the attached location map, claim map, and two sample maps.

The goal was to cover all known types of mineralization including those in recent drill holes CP-06-1 to 6 (T-5529 and T-5615) and CP-07-7 to 8 (T-5631). No previous soil sampling is on record, but in 2004 the showings were sampled and the present grid cut (T-5092), followed by the several IP and MAG surveys from 2004 to 2006 (T-5092 and T-5428).

The area lies in the regional Kamiskotia Gabbroic Complex, reportedly a tholeiitic intrusive overlain by the Kamiskotia Volcanic Complex of basalt and rhyolite. The hummocky area is covered by a variably mixed mature forest and thin overburden of mostly clay, which is often varved. No samples were taken in the few treeless swamps with alders, as the B horizon lies too deep to be reached and might fall into a different sample population that needs a separate orientation study.

Results

The present soil sampling method and type of analyses were clearly successful, for zinc and especially for its associated cadmium, and lead in two cases, in locating the wider area of quartz-zinc veins known from outcrops and near surface intersections in drill holes. The highest values, of the quite ordinary clay sample 438, are from the bottom of the slope down from the richest showing, ZnV1. A near surface extension of the deeper more significant 2.92 m intersection of 10.15% Zn at a vertical depth of 140m, ZnV3 cut off by a fault above, has still to be found, and there is room for it westward and southwestward.

Please refer to the maps with sample locations and values of ZnCdAuAgPb, and the lab certificates with annotations of unusually pale or very dark, or sandy samples.

Mineralizations and Anomalies

The 3 known types of mineralization are:

Au Gold alone associated with pyrite cubes.

ZnCdAuAgPb Sphalerite in quartz veins, <20% Zn, usually with <5 g/t gold and <20 g/t silver, traces of galena, and very sparse pockets of chalcopyrite.

CuAu Chalcopyrite pockets in quartz-veins, with <2 g/t gold.

The present soil anomalies are (in ppm, AuAg in ppb, Fe in %):

Sample	Zn	Cd	Au	Ag	Pb	Th	Cu	Fe
409	368	2.50	7.8	53	9.4	8.6	27	2.7
423	104	0.24	6.3	91	13.1	10.5	32	3.6
434	147	0.43	3.4	60	11.2	8.3	21	3.1
438 =476	1120 1070	7.76 7.81	4.4 7.8	154 158	16.0 16.9	10.6 11.7	40 38	4.4 4.3
446	657	1.15	7.8	39	97.2	2.8	9	0.6
447	291	0.68	3.9	25	30.8	3.5	10	0.7
494	54	0.06	14.0	76	9.9	5.2	16	1.7
Normal	<100	<0.20	<10.0	<100	<20.0	<12.0	<30	<4.5

Zinc anomalies are high probably because of good concentrations in ore grades. Cadmium is only 1% of zinc in ore grades but its very distinctive anomalies leave no doubt about the zinc anomalies, and both agree well with known near surface mineralization. ZnV3 does not show so far, and may be too deep as it is downhole from a fault. Cadmium values are not a side effect of zinc, but are real according to the lab.

Gold anomalies are rather uncertain, although samples over known minor gold mineralization tend towards higher values, and sample 494 with the highest of 14 ppb Au would fall into a gold-only trend. This sample 494 is the darkest gray-brown clay of all samples, possibly also influenced by the swamp. Also other gold analyses did not repeat well, possibly due to the

very small aliquots of only 0.5g. Some repeat analyses of larger aliquots are planned. Total gold as from fire assays or neutron activation could include gold from transported sand grains, and therefore these were not done. However, one would expect that an economic gold deposit would make a conspicuous anomaly.

Silver anomalies were not found, probably because values are <20g/t Ag in zinc ore grade. Only one extreme of 275 g/t Ag at 110.50-110.70m in DDH CP-06-3 is known.

Lead and thorium values in background correlate well, but in lead anomalies the thorium is not anomalous. This could be a useful criteria in selecting lead anomalies. In drill core galena was seen only with much sphalerite, yet only samples 446 and 447 are clearly anomalous in lead.

Copper so far is not anomalous, as the fist-size pockets may be too few.

Iron usually correlates with NiCoCuPbZnMnAs, less with AuAg, but all only at background levels. As one would expect, and as shown in different samples from the same spots, 402-403 (sandy vs. clay), 414-415 (darker vs. sandy), 452-453 (sandy vs. clay), 460-461 (pale vs. dark), 486-487 (darker vs. sandy), all these elements are less when colour is lighter or sand content is higher, but still make clear anomalies at the present <0.3mm size analyzed. In similar samples 416-417 (25 vs. 45cm depth) from the same hole these elements are very similar.

Extremes of such properties, namely pale, very dark, sandy, as well as magnetite and fizz with 10% HCl, should be noted for better evaluation of analyses. The enriched B horizon should be looked for. Pale sand should not be sampled. No influence from various colours was found, only from colour intensity. In statistics the iron ratio could be useful for intensity, and sandy samples should be treated as a different population.

Sampling Procedures

Soil samples were taken on occasion from October 2006 to April 2008, of the enriched B-horizon, and darker colours were often preferred. Mostly clay regardless of topography, often varved clay, and sometimes silt to even coarse sand, were encountered and sampled.

The samples were extracted with a stainless steel auger from the enriched B-horizon, usually at <50cm from surface, below 10-30cm humus and sometimes below a 10-20cm clear leached B-horizon. Only plastic tools and bags were used thereafter. Clean parts were kneaded into a fist-size lump for homogenization, from which 5 - 8 thumb-size flakes were taken for easier drying at room temperature. Clay dried extremely hard, and should be crumbled during drying.

To speed up the process only 5 thumb-size lumps of clay should be picked with a stainless tool from the auger into a plastic bag that can be kept open for drying. Sandy samples need to be much larger to get enough fines.

All samples were rolled with a glass bottle on a melamine board to release enough fines, but without crushing too much sand. Very sandy samples were rubbed in the plastic bag to release the fines. The entire samples were then sieved to <1mm, followed by <0.3mm, with plastic coffee filters (available at Zeller's), the latter very briefly so as to restrict coarse rock particles which could dilute values considerably, even to 10%.

A finer sieve would be better if metal contamination could be avoided when forcing the sample through. However, the present procedure was adequate to show clear anomalies of zinc and especially cadmium.

Aliquots of 5g were sent in paper envelopes to the lab which needed 0.5g for the aqua regia extraction and Ultratrace-1 ICP/MS analyses for \$20.00. Repeat analyses for only gold for \$17.00 by the similar method 1A8 but of a 30g aliquot are pending, however, the expected greater precision may not be necessary for real gold anomalies. Nevertheless it

may show whether gold is distributed evenly and fine enough in soils to use 0.5g aliquots. The aqua regia method 1E1 for \$11.00 is too crude for the important cadmium and silver.

Varieties of soil at one location should be sampled separately. Some promising samples should be collected in duplicate, and new anomalies should be re-sampled in more detail later. A suitable standard, and a duplicate of a promising <0.3mm fraction, should also be introduced at times.

Quality Control

To verify reliability of analyses one test pulp was used as sample 474 and 496, and ZnAgPbCu agreed, but understandably for rock pulp the gold was quite erratic at this 0.5g aliquot. 9 analyses were duplicated, 414, 438 (which is anomalous), 448, 449, 450, 463, 465, 466, 495, and all values except gold were close.

To avoid contamination, the auger was first cleaned with the present sample, or with wet snow in April. First sieve-fulls were discarded, which also prevented the bias of sticking dust which was removed after each sample. The samples must be dry enough so as to avoid caking when crushing and rolling, for proper homogenization. Metal rings must not be worn during any process, and tools with paint, corrosion, or zinc plating must not be used. Abrasion from plastic tools may contaminate with cadmium. The glass bottle should be colourless.

Samples 401 to 467 were taken before drilling, but contamination from drilling is most unlikely except near set-ups and would probably also show as LiMo-anomalies from the core-barrel grease used after CP-06-1.

To check for sample mix-up, fizz with 10% HCl was noted as F1 to F5 for weak to strong, which compares to the 1% to 5% Ca of the analyses. Four samples contained minor magnetite (1% in 432 and 446, 3% in 457, 5% in 460), which however is not dissolved by aqua regia.

Conclusions and Recommendations

The present soil orientation study confirms that conventional sampling of the enriched B horizon followed by aqua regia leach and low detection limits will locate bedrock mineralization of sphalerite, in this case also highlighted by extreme cadmium, and confirmed by lead associated with the quartz-sphalerite veins. Gold alone should also be detectable if rich enough. Method ICP/MS Ultratrace 1, aqua regia extraction, for \$20.00, is considered suitable and reliable. Sampling nodes at <50m should not miss an economic deposit.

As geophysics have been tried and failed, soil sampling may be the only effective exploration method. Neither sphalerite, nor the pyrite cube veins with gold, are conductors. The ubiquitous laminated ilmenite-hematite makes strong IP anomalies that would mask others. Magnetism of the gabbros and ilmenite varies greatly.

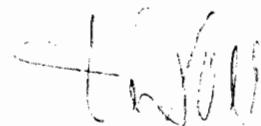

The present soil sampling should be extended over the 4-corners grid south of Highway 576 near 50m picket intervals, with subsequent close sampling around new anomalies. This may also show how suitable the method may be for gold alone before it is continued north of Highway 576.

A larger such soil survey should be done on 50m GPS nodes without cutting a grid, including the copper-zinc trend between Jamieson and Jameland Mines. Orientation sampling is first necessary in the swamps, which cover much of that area.

Respectfully submitted,

25 August 2008

Legend to correlate background metals:

- S sandy, else clay
- L light color } else medium
- D dark color }
- F1 - F5 fizz with 10% HCl, weak to strong,
else nil, approximates % Ca.
- % mt % magnetite, else nil or trace.
