On the Drilling of  
Holes # NU-07-1

On The

Mine Centre-Serine Bay Property

Held By

Numax Resources Inc.

August 7, 2008

By

R.A. Bernatchez, P. Eng.  
Consulting Geologist  
Atikokan Ontario

## Summary

Numax Resources Inc. drilled a single hole on there Mine Centre-Seine Bay Property located 19 km southwest by road from Mine Centre, Ontario. This hole was drilled to intersect a ground VLF-EM anomaly located at 24+80W at 11+00S. The hole is also located at UTM coordinates, Nad 83, Zone 15, at 517200E and 5393225N. The hole was drilled at azimuth 158 deg at a -45 deg angle. The hole was collared in bedrock and stopped at 172.8 m. The drilling took place between December 14, 2007 and January 4, 2008. Logging and sampling took place between December 17, 2007 and January 10, 2008. The assay table, log, report and drafting took place between January 10, 2008 to August 6, 2008.

The hole intersected coarse and medium grained gabbro, leuco gabbro, mafic, intermediate and felsic altered volcanic rocks, pillow and massive flows, tuff, and chert, diorite and felsic intrusive tonalite. All rock types were mineralized with varied levels of sulphide mineralization, consisting of pyrrhotite, chalcopyrite, pyrite and magnetite. The sulphide appears as disseminated grains, stringers, massive seams and as net textured sulphides in the coarse to medium grained gabbro. The gabbro outcrops near the drill hole is layered from light colored (plagioclase phase) to dark green coloured hornblende-pyroxene rich mafic phase.

The analysis of the core has confirmed the presence of copper, nickel, cobalt, platinum, palladium, gold and silver in anomalous levels. A total of 110 cut samples of core were analyzed for gold, platinum, palladium and 42 multi-elements.

## Conclusions

The drilling program was successful in identifying a new and major Northeast striking mineralized structure between Bad Vermilion Lake and Seine Bay of Rainy Lake.

The assay results shows a mineralizing structure over one 100 meters wide containing anomalous but sub-economic values of copper, lead, nickel, cobalt, platinum, palladium, gold and silver mineralization.

No previous work has been carried out on this structure.

The NE structure appears to parallel other gold bearing structures located to the east on the property.

This structure remains a major exploration target for the discovery of large tonnage low grade gold, platinum, palladium, copper, nickel, cobalt and silver mineralization.

## Introduction

The Mine Centre area has experienced several episodes of exploration for gold, base metal (copper-zinc) massive sulphide deposits, iron-titanium magmatic type deposits and copper-nickel-PGM type deposits. Exploration activity continues to this day for the same mineral deposits.

Gold exploration has been carried out intermittently in the Mine Centre area for the past 40 years. More recently, Q Gold Resources Inc. has been carrying an extensive and ongoing exploration gold evaluation in similar geological environments on a property to the east adjacent to Numax's property.

More recently, MetalCorp has carried further exploration on the former North Rock property located about 25 km west of Mine Centre near Grassy Bay of Rainy Lake. MetalCorp has now identified a very significant zone of copper-nickel-PGM bearing gabbro that was formerly evaluated for only copper. The discovery of this mineralization has been significant in directing Numax Resources Inc. in staking and carrying further exploration on their property.

The work recently carried out by MetalCorp and Numax Resources Inc has indicated that the geological and mineral setting on both properties are very similar. This observation has significant implications for the NuMax property. This property has not been previously explored for this style of mineralization.

Work carried out to date by Numax has identified a copper-nickel-PGM-gold-silver zone of mineralization along a strike distance of over 2.5 km long. The mineralization is contained within a series of layered gabbro rocks located 100-200m southeast along the east margin of a strong magnetic anomaly which extends northeast southwest for over 40 km, from Bad Vermilion Lake to the west end of Rainy Lake. The copper-nickel-PGM bearing gabbro located on the MetalCorp property located 20km to the west is contained within a similar layered gabbro intrusion.

## Property Location, Access and Description

The property is located on the Bliss Lake Sheet claim map located 20 km southwest of Mine Centre, Ontario. It can be reached by the all-weather Barber logging road starting 9.5 km west from Mine Centre, Ontario located on Highway 11, 80 km west of Atikokan and 276 km west of Thunder Bay, Ontario. Travel southerly along this road for 7 km to the Bliss road junction. Turn left and travel easterly for about 3 km to reach the northerly boundary of claim numbered 4205425. The diamond drill hole NU-07-01 was drilled on claim 4205425 and portion of the work is to be applied to 4206036 and 4206037. The hole was drilled at the northwest corner of the Discovery Trench located near line 25+00W at 11+00S. One can drive directly to the trench with a ½ ton truck when the road is dry. The road leads to the north and east side of the Discovery Trench.

The claim list is in Appendix A. Diamond drill hole numbered NU-07-01 was completed on claim **4205425** near line **25+00W at 24+80W at 11+00S**. The hole was at an **azimuth of 158 degrees** and at a dip of **-45 degrees**.

## Regional Geology

The geology of the Mine Centre area was recently mapped by K.H. Poulsen for the Ontario Geological Survey, Mineral Deposits Circular 29, "Geological Setting of Mineralization in the Mine Centre-Fort Frances Area, 2000".

Poulsen describes the rocks of the area as follows:

*The rocks of the Mine Centre-Fort Frances area lies within a boundary zone between the Wabigoon and Quetico sub-provinces of the Superior Structural Province. In the Atikokan-Fort Frances area of Ontario and adjacent parts of Minnesota, this boundary is defined by a system of steeply dipping dextral faults, the largest of which are the Quetico and Rainy Lake-Seine River faults. These major wrench faults bound a "wedge" of crust that is structurally discordant from both provinces, but because of a gross lithologic similarity, is generally considered to be part of the Wabigoon Sub-Province.*

### ***Wabigoon Sub-Province***

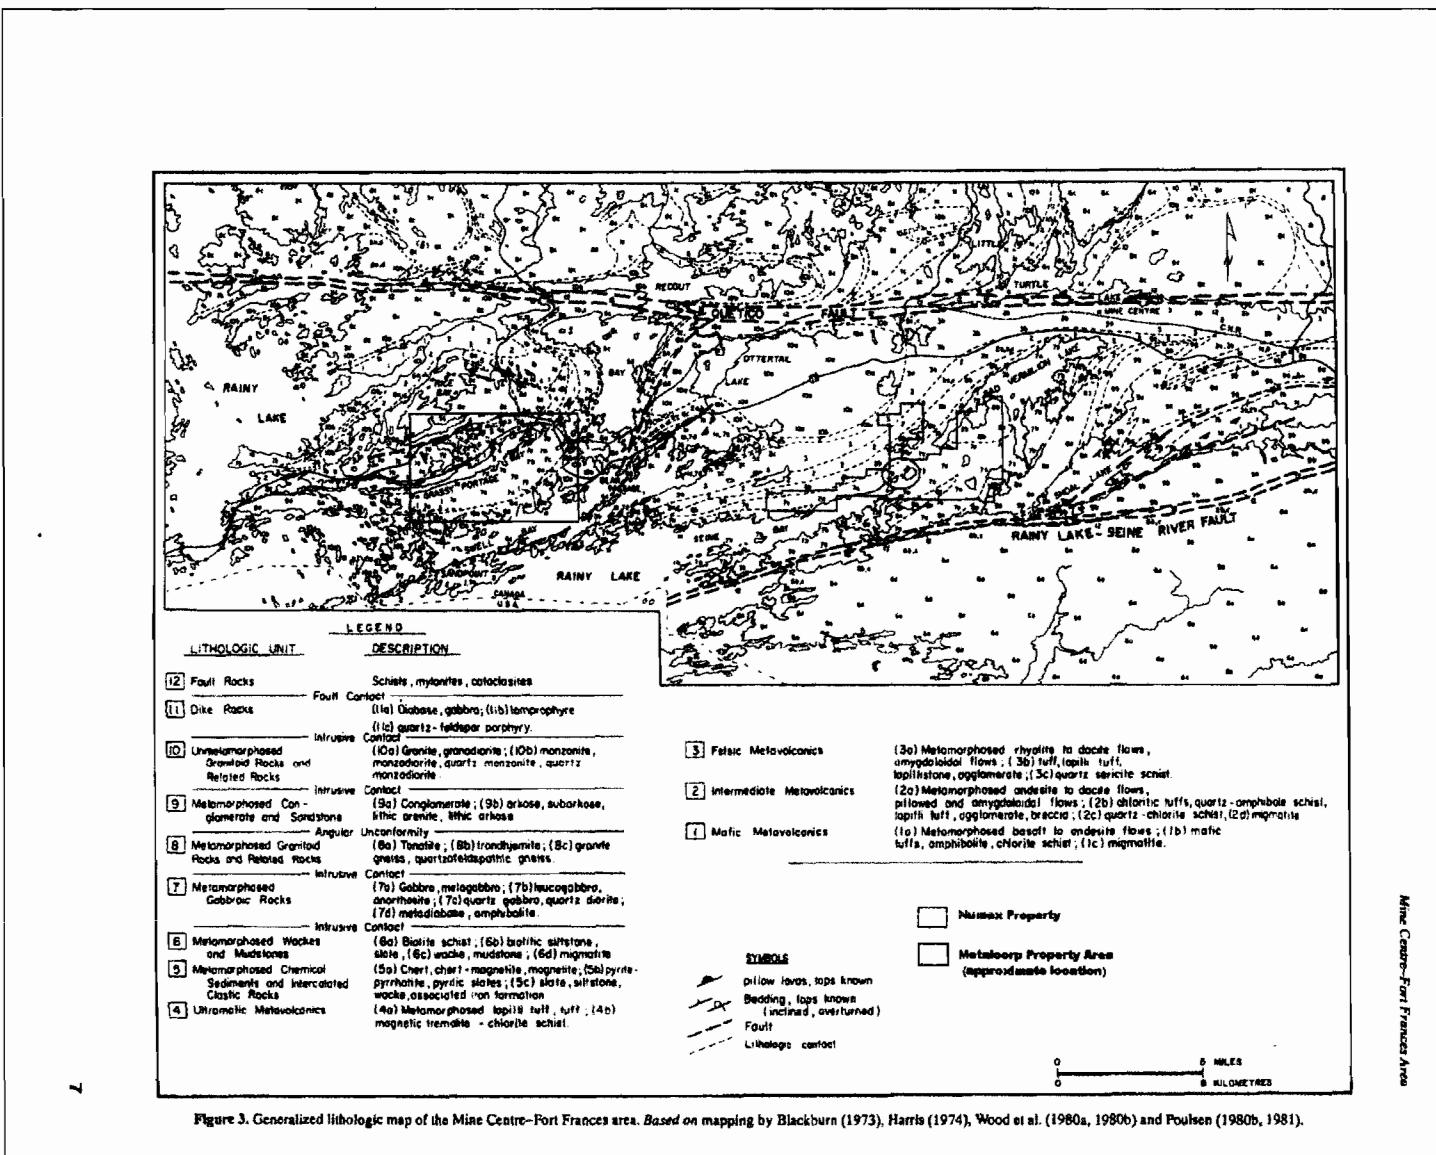

*The structure of the Wabigoon granite-greenstone terrain is dominated by dome features of variable size. The largest of these, such as the Rainy Lake complex and the Irene-Eltrut Lake complex, are greater than 50 km in diameter and are composed of smaller gneissic domes, central batholiths and marginal crescent granitoid intrusions. The larger complexes and smaller gneissic domes have been interpreted as first- and second order gneiss diapers, respectively, which are the product of gravitational, solid state remobilization of tabular batholiths beneath the supracrustal sequence (Schwertner et al. 1979).*

*Supracrustal metavolcanic and metasedimentary rocks now occupy the margins of the gneissic domes, with the largest stratigraphic thicknesses preserved between the first-order structures. Metavolcanic rock types dominate and consist of metabasalt flows with local accumulations of flows, pyroclastic rocks and epiclastic rocks of intermediate to felsic composition. Metasedimentary rocks such as conglomerates, wacke, and mudstone and iron formation form units within the volcanic sequences. A dolomite unit with algal stromatolite mounds occurs within the Steep Rock Group at Steep Rock Lake, north of Atikokan. Numerous Stocks, commonly of quartz monzonite, intrude both metavolcanic and metasedimentary supracrustal rocks.*

*Wabigoon Sub-province supracrustal rocks are metamorphosed to assemblage characteristic of the green schist and amphibolite facies (Ayres 1978) highest metamorphic grades occur adjacent to the first-order structures.*

*With the exception of a few northwesterly striking Proterozoic diabase dikes, most of the Wabigoon Sub province rocks in the Atikokan-Fort Frances area are of Archean age. Although there is a discrepancy among ages derived by geochronological methods, it is clear that the rocks of the area were thermally active in the interval of about 2700 to 2400 Ma. The oldest ages reflect widespread igneous activity, whereas successively younger ages are likely the result of metamorphism, metasomatism and crustal uplift.*

Figure 1 – Regional Geology of the Mine Centre Area by H. Poulsen.

### **Local Geology**

The local geology around the working area, consists of metamorphosed layered gabbro-anorthosite sills containing both oxide and sulphide mineralization. The large, steeply dipping sill body is located along the southwest shore of Bad Vermilion Lake and extends southwestward for 14 miles along the north shore of Seine Bay. This sill is very similar to the Grassy Portage layered gabbroic sill. The layering is expressed by modal variations in the mineralogy, chemical variations across strike and locally by rhythmic mineral layering, which is well exposed in the Bad Vermilion area and to the southwest. Rock compositions range from melagabbro to anorthosite, with plagioclase compositions in the range of An45-80. The intrusion displays systematic internal variations in composition, which, when compared to other intrusions of similar type, suggest that the Seine Bay-Bad Vermilion sill intrusion faces northward.

Pillowed meta-basalts are exposed within the central part of the Seine Bay-Bad Vermilion sill. These may be interpreted as large assimilated inclusions or, more likely as inter-fingered country rock that separated the two individual sills. Much of the base of the sill intrusion is truncated by the Rainy Lake-Seine River fault, while the upper contact is occupied by a sill of trondhjemite of unknown genetic relationship to the gabbroic rocks. In addition to the large intrusions, numerous small sills and dikes cut the metavolcanic and metasedimentary rocks sequence. They are commonly 50 to 100 m thick and are composed of medium-grained, massive to strongly foliated amphibolite that locally resembles meta-diabase. There is some compositional differentiation across the strike of many of the wider intrusions, with the development of quartz + plagioclase + magnetite accumulations toward the upper margins of the sills. Weak to moderate magnetism and irregular patches and veins of epidote-rich alteration are characteristic of these intrusions.

### **Gabbro Hosted Mineralization**

The mineralization described here is of the Grassy Portage and Seine Bay-Bad Vermilion Lake intrusion. Basal segregations of chalcopyrite-pyrrhotite-pentlandite form important occurrences along the northern margin of the south-facing Grassy Portage intrusion. The best example of this type occurs at the North Rock deposit, where 300,000 t of material grading 1.89% copper has been outlined. The mineralization is hosted by gabbro, melagabbro leucogabbro near the base of the Grassy Portage intrusion where it is in contact pillow lava and pillow breccia. Mineralization consists of heavy disseminations of chalcopyrite, and pyrrhotite with minor pentlandite and pyrite. Ilmenite, apatite and molybdenite are present locally. Similar mineralization has been discovered in the Seine Bay-Bad Vermilion Lake intrusion, with one exception. Sphalerite was noted and no molybdenite was found in the samples recently obtained during this program. The sulphide mineralization in both areas shows textures that suggest a magmatic origin, whereas deuterian or metamorphic remobilization is evidenced by the presence of sulphide veins and local hydrothermal alteration.

In the central and upper portion of both intrusions, substantial accumulations of iron-titanium mineralization occurs as lenticular zones of disseminated to massive magnetite and ilmenite with apatite and local rutile.

### **Exploration History**

Mineral Exploration was carried out in the property and in the vicinity starting back in 1911. This exploration consisted of prospecting, trenching, magnetometric surveys and diamond drilling evaluating the iron and titanium potential of the titaniferous magnetite bodies in the Seine Bay-

Bad Vermilion Gabbro intrusion. These mineral occurrences were re-evaluated again in the 1917-18, 1943, 1950s, and 1980s and as recently as 2000. The titanium content is contained mainly within the titaniferous magnetite as the mineral ilmenite. Some areas of the formation do contain rutile. The rutile concentration has not been thoroughly explored.

Most of the early work was focused on the high iron-titanium areas of concentration of the formation. Sampling by the resident geologist, Mike Hailstone, from Kenora in 1987 identified a new potential in the Seine Bay area for its copper, nickel and PGM potential.

Abundant work has been carried out on the adjacent property to the north and along the west shores of Bad Vermilion Lake. Massive sulphide mineralization consisting of pyrrhotite and chalcopyrite was encountered in some drilling on this property. The drill log information submitted to the resident geology office in Kenora shows no assay for copper, nickel and PGM metals.

The most recent work by Numax Resources in 2005 and 2006 has identified a potential for copper, nickel and PGM. The 2006 program has identified significant copper, nickel, PGM and gold potential along a major mineralized system located between Seine Bay and Bad Vermilion Lake. This mineralization appears to be located along the southern contact (base) of the Seine Bay-Bad Vermilion Lake Gabbro Intrusion.

The following map illustrates the historical exploration carried out on the property from 1911 to 1958.

Mineral exploration was carried out on the adjacent property to the north held by Bob Fairservice. A drilling program was carried out in 1984-85 by Titan Titanium International, Inc. evaluating the iron, titanium and phosphate potential of the Fe-Ti deposits located along the southwest shore of Bad Vermilion Lake. A program consisting of line cutting, ground magnetic survey and the drilling of 17 holes totaling 4,174 feet and was carried out. The 1984 and 1985 drilling program has resulted in the delineation of a total drill indicated resource of 3,450,000 tons in all, of which 1,270,000 tons graded 15% to 17% titanium oxide and an average grade of about 45% Fe.

In 2000, Stephana Resources Ltd. carried out a geological, rock geochemical geophysical survey and metallurgical testing on the Fe-Ti deposit presently held by Bob Fairservice. The Geophysical program delineated several parallel magnetic and electromagnetic anomalies associated with the Fe-Ti deposits. A rock sampling program has identified a potential gold system within the Fe-Ti deposits.

## Assessment Distribution

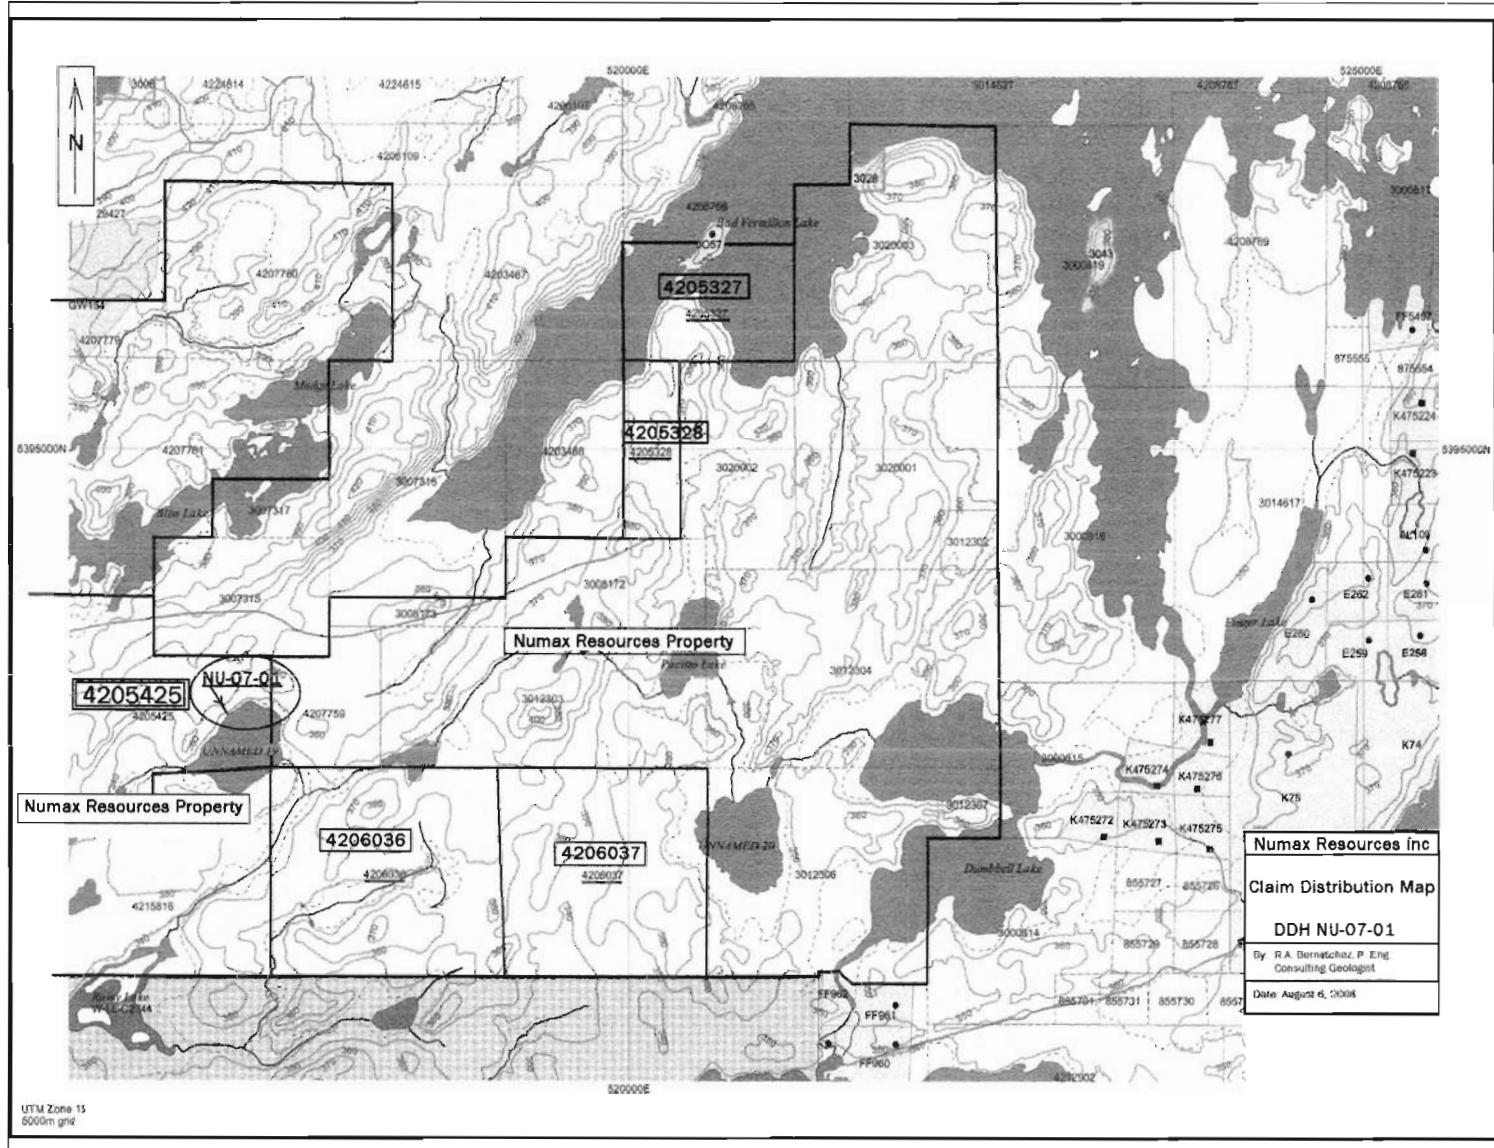

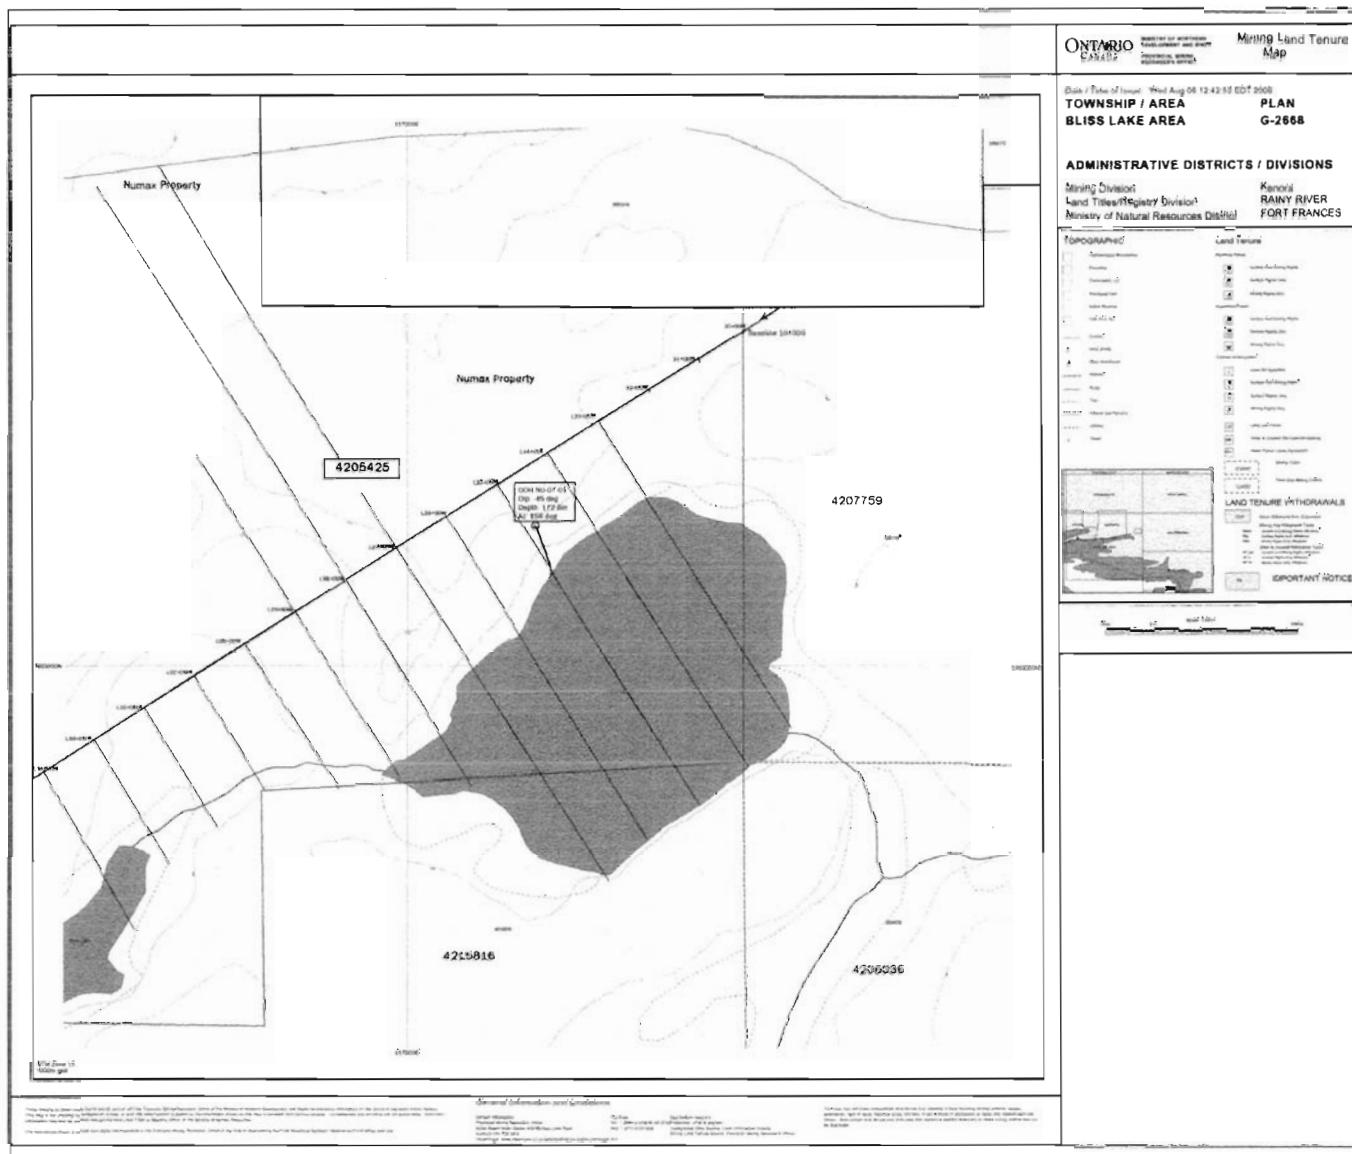

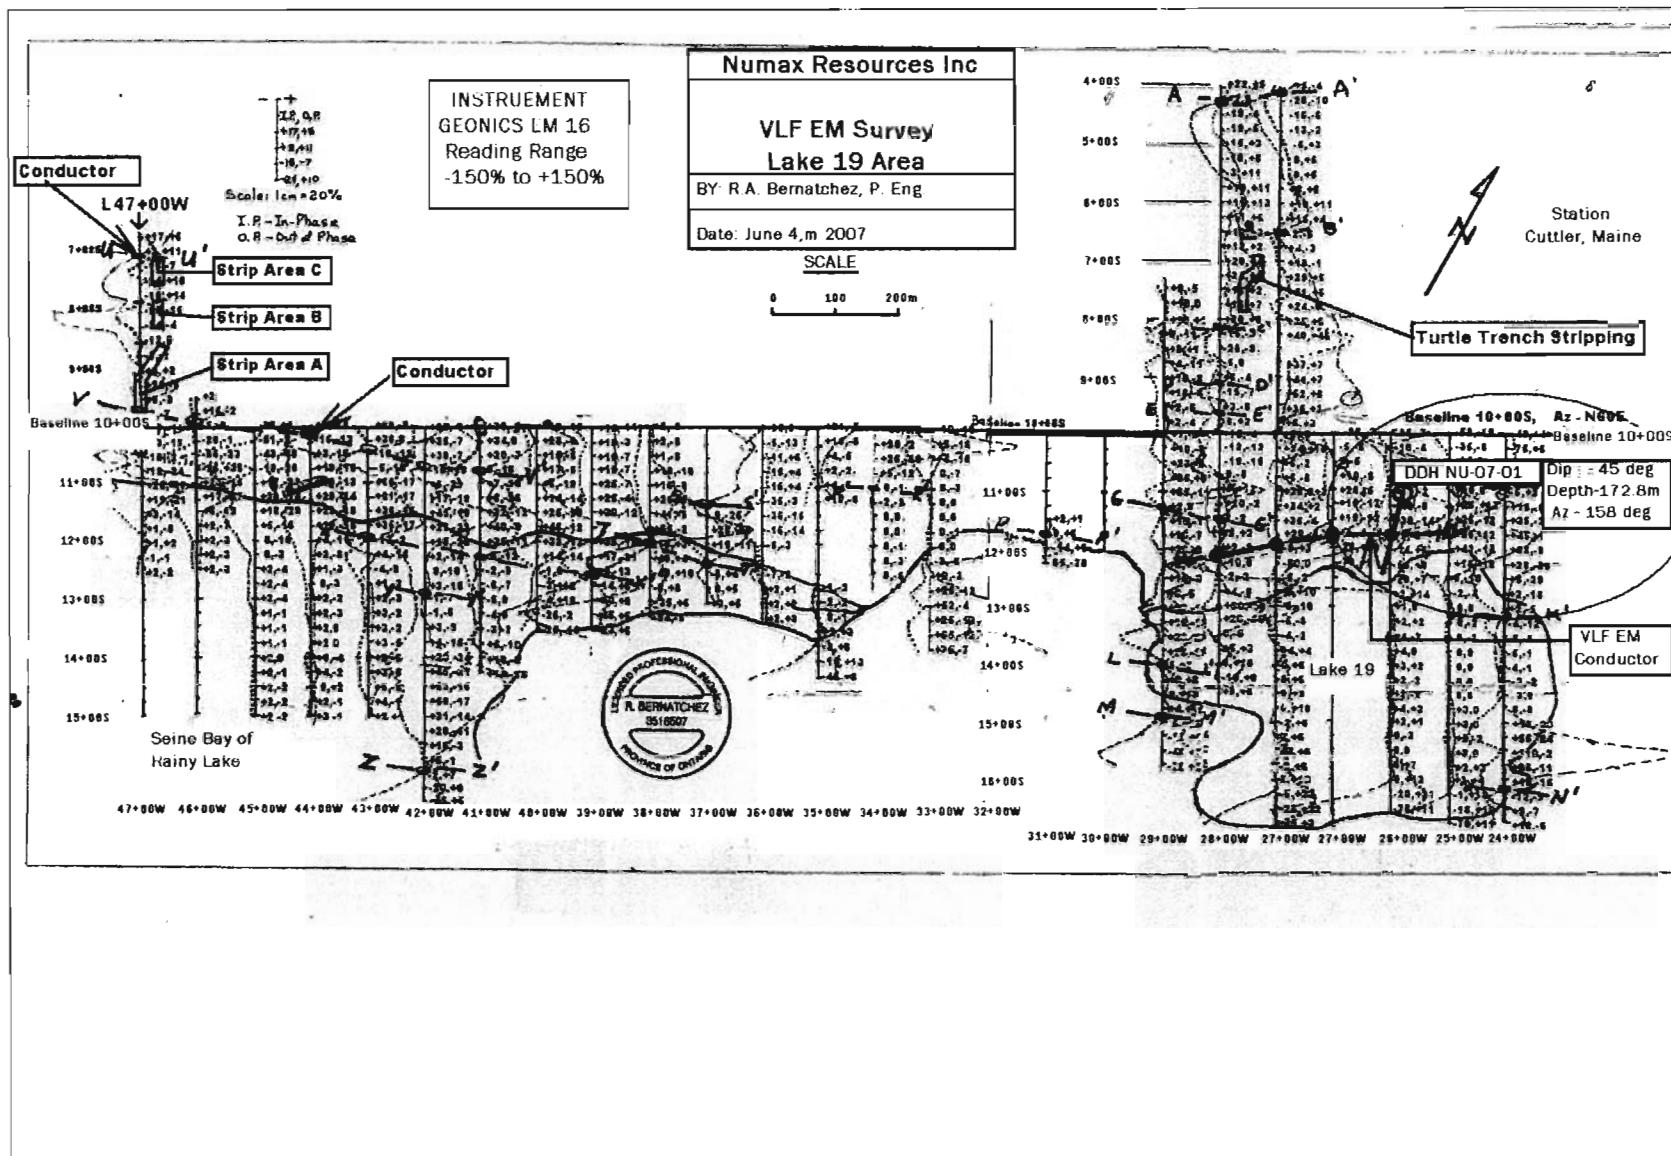

Figure – 2 – Claim Map Distribution showing where DDH NU-07-01 was drilled on Claim 4205425 and where work is to be allocated to Claim 4206036 and 4206037.

Figure -3 – Grid Map Showing Location of Diamond Drill Hole NU-07-01.

Figure 4 – Below is a map of the VLF EM Survey showing the conductor drilled on line 25+00E at 11+00S

## Results

### NuMax Resources Inc.

Mine Centre Property

Sampled Sections and Assay:

Hole # NU-01-08

Location: Line 24-80S, 11+00S, West Shore of Lake "19"

Date Started: December , 2007 Date Finished: January 2008

Sampled And Directed by: R.A. Bernatchez, P. Eng., Consulting Geologist, Atikokan, ON.

Core cut by: Anthony Burkholder, Mine Centre

**Core Length Only Measurements In Feet**

*Anomalies Range (relative to values in this hole)*

Au - Low - 10 to 20 ppb

Medium - 20 to 100 ppb

High - > 100 ppb

Platinum - Low - 15 to 19 ppb

Medium - 20 to 49 ppb

High - > 50

Palladium

Low - 10 to 19 ppb

Medium - > 20 ppb

Silicate - Low - 4 to 9 ppm

Medium - 10 to 15 ppm

High - > 15 ppm

Copper - Low - 200 to 499 ppm

Medium - 500 to 999 ppm

High - > 1000 ppm

Nickel - Low - 50 to 199 ppm

Medium - 200 to 499 ppm

High - > 500

			472.1*									

94.9 feet not sampled (83.3% of core sampled)

Conversion

1000 ppb = 1 gram

10,000 ppm = 1%

Note: Sections of table left blank indicated sections of un-sampled core. Total core cut indicated after each section.

Table – 1 – The table above is a summary of all the assays taken from DDH NU-07-01.

The net texture sulphide in the gabbro contains anomalous levels of copper, nickel, cobalt, platinum, palladium, silver and gold. The sulphides in the gabbro assayed up to 0.15% copper, 0.083% nickel, up to 0.12 g/t platinum and up to 0.22 g/t gold.

The seams of bedded massive sulphides contain up to 0.5% copper over 0.3m.

Silver was present throughout all sulphide bearing rocks ranging from 1 g/t and up to 10 g/t.

Cobalt was detected up to 346 ppm (0.035%)

Lead is present in all samples ranging from 67 ppm to 499 ppm.

Zinc values ranged from 11 ppm to 120 ppm.

### **Recommendations**

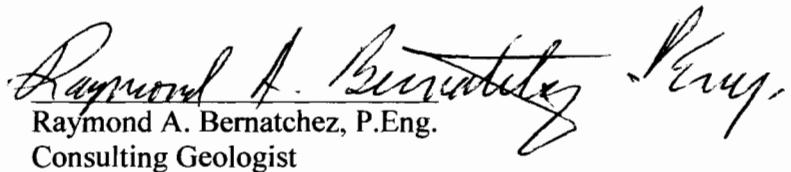

Additional drilling is recommended in this area. Many VLF EM conductors were identified along the new northeast trending Bad Vermilion-Seine Bay structure. Significant shearing was noted along the southwest corner of Lake 19 and along the creek draining to the southwest into Seine Bay. This shear zone forms part of the 100+ meter wide mineralized structure intersected in DDH NU-07-01.

Abundant azurite mineralization was observed along the northwest shores of Seine Bay in the fall of 2006. This mineralization is probably locally derived from the rocks located along on the west shores of Seine Bay. Chalcopyrite mineralization was also observed in ultramafic flows located 30 meters northwest from the azurite mineralization.

A minimum of 6 holes 200 meters deep at a -45 degree dip should be carried out along the Seine Bay-Bad Vermilion Lake Shear Zone.

This shear zone has a minimum distance of 2 kilometers on the property.

This mineralization forms part of a larger system of mineralized layered gabbro, sheared mafic, intermediate and felsic volcanic sequence extending for about 10km on the property.

Raymond A. Bernatchez, P.Eng.  
Consulting Geologist

Drill Hole Identification

## DRILL HOLE IDENTIFICATION

Name of Claim Holder or Mining Land Holder  
Numax Resources Inc

Company Hole Identification Number NU-07-01	MNDM Core Library Identification (Office Use Only)
--	--

## CO-ORDINATE INFORMATION

Indicate method used to obtain drill hole location co-ordinate:

- |  |   |   |
|--|---|---|
| <input type="checkbox"/> Don't know        | <input checked="" type="checkbox"/> GPS reading (Geographic Positioning System) | <input type="checkbox"/> MNDM CLAIMaps system   |
| <input type="checkbox"/> NTS 1:250,000 map | <input type="checkbox"/> NTS 1:50,000 map                                       | <input type="checkbox"/> Ontario OBM Series map |
| <input type="checkbox"/> Paper claim map   | <input type="checkbox"/> Sketch map   | <input type="checkbox"/> Surveyed co-ordinates  |
| <input type="checkbox"/> other             |   |   |

## DRILL HOLE COLLAR LOCATION CO-ORDINATES

Collar Location Co-ordinates. You may provide co-ordinates in UTM or Latitude and Longitude

Datum	NAD 27 or 83	83
UTM	Zone 15, 16, 17 or 18	15
	Easting	5172000
	Northing	5393225
Latitude and longitude data (degrees/minutes/seconds or decimal values)	Latitude	
	Longitude	

## OTHER DRILL HOLE DATA

Hole Type (examples percussion, diamond drill, underground)	diamond drilling
Year Drilled	2007-2008
Azimuth	158 °
Dip	-45 °
Length (metres)	172.8m
Overburden Depth (metres)	on bedrock

## ELEMENTS PRESENT ABOVE DEFINED THRESHOLD LEVELS
