Scope of work and objectives

Superior Diamonds Inc. has requested a Stage 1 archaeological investigation of thirty drill sites in the region of Freure Lake and Mameigwess Lake. Drilling is planned for late January or early February 2008. Very little information currently exists in the archaeological literature regarding the historic and prehistoric land use and its archaeological visibility in this specific study area. However, archaeological investigations have occurred in the surrounding region and the information from these surveys regarding site locations is used here to assess the study area (Figure 1).

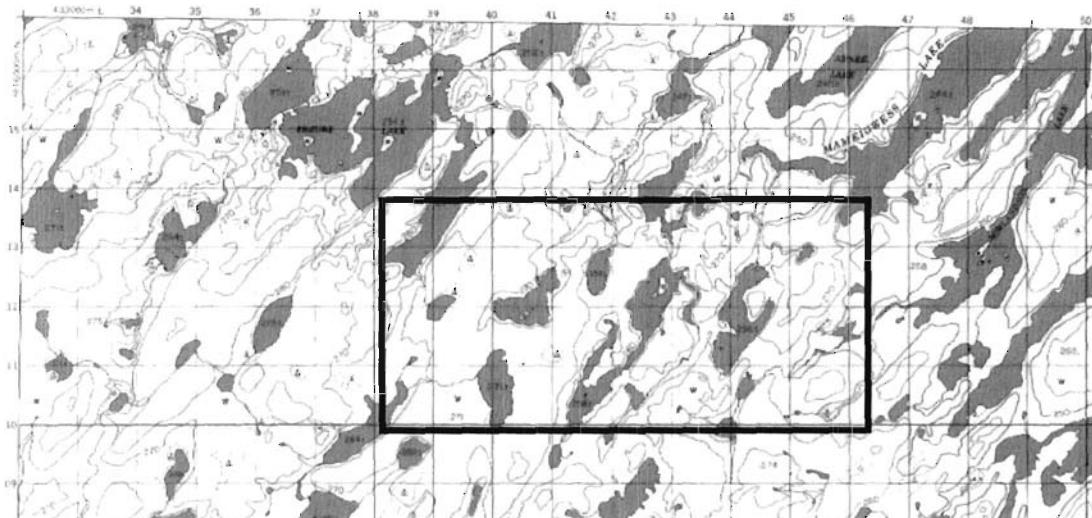

Figure 1. Northwest corner of the NTS mapsheet 43D/5 showing the study area.

This report is intended to provide Superior Diamonds Inc. with some background information about archaeological and heritage sites generally (locations and site antiquity) in northwestern Ontario to place into context any heritage concerns. In addition, this report reviews the available map and physiographic information to assess the heritage potential of the specific drill site locations.

The limitations of this report are substantial on several fronts.

1. First, there is a significant lack of archaeological investigation in the immediate study area and in northwestern Ontario in general. This means that there are significant gaps in the database and in our understanding of how the landscape was used in the past and how this is represented archaeologically.
2. The lack of high-resolution maps for the study area makes interpretation of some of the landscape features difficult or impossible without ground truthing. Local traditional knowledge can provide important information about recent and historic land use patterns that can serve as proxy variables for archaeological site prediction.
3. The lack of traditional knowledge that is currently available for review for this Stage 1 assessment is a serious limitation. Dr. Scott Hamilton provided information about one travel route from the Kayahna land use studies (Kayahna Tribal Council 1985).
4. To my knowledge few if any archaeologists have reviewed the winter drilling process to assess the impact¹ that this activity may have on archaeological sites.

¹ Archaeological sites in the boreal forest are generally located within the first 50 cm beneath the ground surface. It is my understanding that the proposed drill sites will require a small core to be drilled and removed. While this specific action will have little impact on an archaeological site the preparation of the drill hole may impact artifacts and/or a site. Impact to an archaeological site occurs when the ground surface is cleared of bushes and/or trees and the roots are disturbed or if the ground surface is scraped to create a flat or even surface.

For thousands of years Aboriginal hunters and gatherers have engaged in complex activities related to making a living, to social and political events, and to spiritual beliefs in the boreal forest regions of northwestern Ontario, Quebec and in the western Provinces. The record of these activities (the Oral Tradition, artifacts and archaeological features) constitutes an important resource that documents regional human history and it details the connection between First Nations peoples and the land. Archaeological and heritage sites in northwestern Ontario record the intensive use of the watercourses, adjacent lands and local biotic and lithic resources. An archaeological site is defined in the Ontario Heritage Act as “property that contains an artifact or any other physical evidence of past human use or activity that is of cultural heritage value or interest” (Ontario Regulation 170/04). Past human behavior is not typically represented by only a few activity locations. Rather, archaeological sites, representing the full range and complexity of hunter and gatherer life throughout the post-glacial period, are distributed across the landscape.

People who used the Freure and Mameigwess lakes region in the past likely made use of specific landscape features such as eskers, changes in elevation, geological formations, forests, lowlands and water sources to harvest resources, as travel corridors, for shelter and settlements and for ceremonial and sacred functions. A strong correlation is thought to exist between certain environmental features and archaeological site distribution. 1: 50,0000 digital National Topographic Survey maps and satellite imaging maps are available and were used for interpretation of the study area. The UTM coordinates of the proposed drill sites were placed on the NTS maps and assessed in terms of their association with certain landscape features. It is considered that this evaluation of proximity could have some inherent inaccuracies. This relates to estimates that NTS topographic map data might be only accurate to within ± 150m. Archaeologists infer the importance of landscape features with regards to their heritage potential based on prior archaeological research in the surrounding boreal forest zone, and on information about how First Nations people used the landscape historically as recorded by early explorers, fur traders and anthropologists. These interpretations can be significantly enhanced with access to locally-held knowledge about Aboriginal land use practices.

The remnants of the activities that took place at these locations are not always readily visible archaeologically for a number of reasons. Human activities can be ephemeral, leaving only a light footprint on the landscape. For example, travel corridors or briefly used winter hunting camps may not leave an easily identified archaeological signature. Large summer gatherings in contrast, are fairly well represented in the archaeological record because of the intensity of occupation results in the deposition of a significant quantity and variety of artifacts; soil disturbances, associated features. Furthermore, the predictability of the location of these camps makes them more routinely identified and inspected by field archaeologists. The lack of preservation of organic materials in the acidic boreal forest soils results has resulted in the loss of many cultural materials. This seriously hinders the archaeologists ability to examine the full range of past human land and resource use and results in the under representation of many activities.

The archaeological site inventory is heavily biased by the fact that sites are only documented when archaeologists have had an opportunity to visit the locality. For much of Canada, no such archaeological inspection has been done. The absence of sites in a particular area therefore does not necessarily indicate a true absence of artifacts or sites, but rather that the area has never been investigated by an archaeologist. While archaeological sites have been recorded at Attawapiskat Lake, the record is strongly biased to the current lakeshore. Until recently, archaeological investigations were restricted to lake and river shorelines and very little, if any, time was spent looking for sites even 10

meters inland or on the smaller inland lakes. This has created the incorrect impression that foragers used only the littoral edges of larger water bodies. We know from recent surveys in the boreal forest that sites are much more widely distributed across the landscape because people made use of the resources of the inland lakes, streams and tributaries, the eskers and upland areas, and important resources (such as stone material for the manufacture of tools) that are not necessarily close to current water bodies.

Archaeology in the study area

There has been no systemic collection of archaeological data and very little published traditional knowledge regarding the area of the proposed drill sites located just southeast of Freure Lake and southwest of Mameigwess Lake. The Ontario Ministry of Culture and Heritage has no record of any archaeological sites within 10 km of the proposed drill pad locations. A number of shoreline archaeological sites are recorded on Attawapiskat and Kabania Lakes located some 20 km to the south. David Riddle (a retired Manitoba archaeologist) recorded the sites in 1980 as part of an archaeological survey of Attawapiskat Lake, and only a summary report is available (Riddle 1982). The current inventory of archaeological sites in the boreal forest of northwestern Ontario is severely biased towards the shorelines of major lakes and rivers. The highest densities of documented archaeological sites in northern Ontario are in regions that are currently heavily utilized or in the few areas where archaeological surveys have been conducted. As such, there are huge tracts of land in northwestern Ontario that has never been investigated for their archaeological potential. The proposed drill sites are located in such an area. It is important therefore to understand the environmental context of other archaeological sites in northwestern Ontario to evaluate the heritage potential of drill site locations.

Archaeological sites that date to as early as 8,500 to 9,000 years ago have been recorded northwestern Ontario. Sites in the Thunder Bay area (Cummins, Brohm and Biloski Sites) represent the earliest use of the area by people along ancient glacial Lake Minong shorelines (MacNeish 1952; Julig et al 1990; Hinshelwood and Webber 1987; Hamilton 1996). The people were likely attracted to the caribou and other subarctic and tundra animals and plants. At this time the landscape would have looked much different than today due to the receding glacial lakes and melt water runoff. In the absence of Pleistocene geomorphic mapping, changes in elevation or a break in the slope across a relatively flat landscape may be our only means of proposing the location of ancient raised shorelines of water bodies during the deglaciation period. Archaeological sites have been associated with these ancient landscape features although in northwestern Ontario sites associated with these features are under-represented largely because the areas are not comprehensively mapped and difficult to access.

Lakes, rivers and streams are significant landscape features and archaeologists have typically relied heavily on hydrology as an important proxy variable for assessing the archaeological potential of an area. Water bodies were important for hunters and gatherers because they were a source of drinking water, they can be rich in a variety of resources (fish, wild rice, beaver, muskrat), they attract other large mammals, and the shorelines are often ideal locations for camps in the spring to fall seasons. Archaeological sites are routinely found in association with large water bodies particularly in sheltered bays, at locations where rivers or streams flow into or out of lakes, near good fishing locations and along portage routes. Virtually no systematic archaeological field reconnaissance has been conducted along minor lakes and streams, or in upland regions removed from littoral situations. I and other archaeologists have found sites associated with these minor water bodies but the opportunity and logistics of systematically searching these locations make these sites rare. A case in point is the Wapekeka burial site (FLJj-1) located on the ancient shoreline of a small inland lake near Big Trout Lake (Hamilton 1991; 2004). The dates from this burial site demonstrate unequivocally that people occupied the northern forest some 7,500 years ago. Furthermore this site illustrates that archaeological sites are associated with

landscape features that were formed during the early Holocene and may not necessarily be directly related to current water bodies or shorelines.

Method

With the aforementioned limitations in mind the archaeological potential is determined for each of the proposed drill areas and described as high, medium or low. The assignment of these levels is meant to characterize the area of the drill site not only the specific drill site location and is based on the information that is currently available.

- **Low potential** is assigned to an area that is more than 150 meters from a current water body (lake, river, stream), is not located on or within 30 meters of a break in slope nor are there any geographic features (i.e. eskers) that might be associated with past human activity. Given the lack of association of the low potential area to geophysical and hydrological features the probability of an archaeological site being located in this area is considered to be low.
 - **Low-medium potential** is assigned to areas that fall just outside of the medium potential criteria. For example if the area is 40 meters from a break in slope or it is 160 meters from a current body of water then this classification might be appropriate.
- **Medium potential** is assigned to an area that is associated with at least one significant landscape feature such as a break in slope (within 30 meters), within 150 meters of a current water body or the area is near a physiographic feature such as an esker or ridge. There is some probability of an archaeological site being located in a medium potential area based on the available information.
 - **Medium-high potential** is assigned to areas that fall just outside of the high potential criteria. For example if the area is 60 meters from a water body this classification might be appropriate.
- **High potential** is assigned to areas that are within 50 meters of a water body. High potential is also associated with the occurrence of multiple significant landscape features such as within 30 meters of a break in slope, within 150 meters of a current water body or it is associated with a physiographic feature such as an esker or ridge. A high potential area has a significant probability of possessing an archaeological site.

These categories are meant to provide guidelines for assigning archaeological potential. In situations where proposed drill sites fall just outside of the above described criteria some flexibility to the assigned criteria should be expected.

Area 1

Proposed drill site	1-3	Low potential
Proposed drill sites	1-1, 1-2,	Low-medium potential
Proposed drill sites	1-4, 1-5, 1-6	Medium potential

The area around the proposed drill sites 1-1 and 1-2 has low to medium archaeological potential (Figure 2). These drill sites are within 30 meters of a break in slope but well away from the current water body. The proposed drill site 1-3 has low potential since it is well away from a break in slope or a current water body. The proposed drill sites 1-4, 1-5 and 1-6 are on the west edge and run parallel to the break in slope just south of the east arm of Freure Lake. These proposed drill sites are therefore located in an area of medium potential. It is possible that this contour represents the ancient shoreline of this water body and therefore this location has medium archaeological potential.

Figure 2. Proposed drill sites Area 1

Area 2

Proposed drill sites	2-2a², 2-2b, 2-3, 2-4	Low potential
Proposed drill site	2-1	High potential

The proposed drill sites 2-2, 2-2b, 2-3, 2-4 are located in an area that has a low potential for archaeological resources since they are greater than 150 meters from the small inland lake and they are not associated with a break in slope (Figure 3). The proposed drill site 2-1 is on a break in slope and is approximately 70 meters north of the water body. This location may be associated with an ancient shoreline. This location has a high archaeological potential.

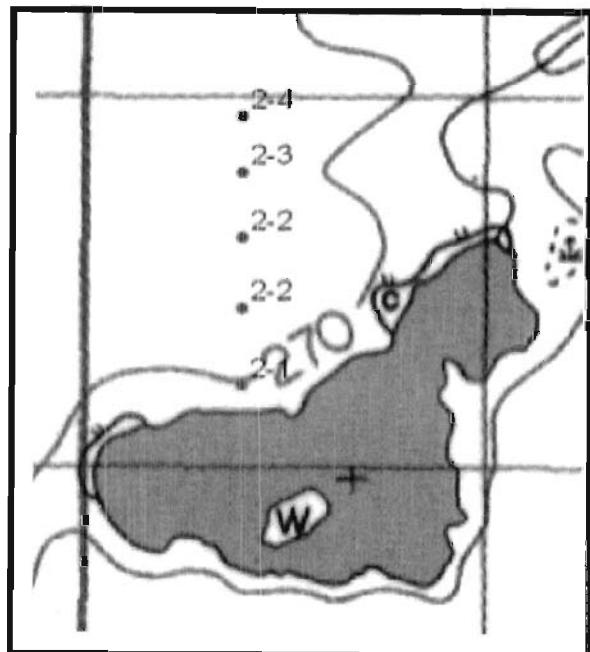

Figure 3. Proposed drill sites Area 2

² There are two drill locations labeled 2-2.
The location at E440396 N5812432 is labeled 2-2a.
The location at E440396 N5812622 is labeled 2-2b

Area 3 and 4

Proposed drill sites 3-1, 3-2, 3-3, 3-4, 3-5, 3-6, 3-7
Proposed drill sites 4-1, 4-2, 4-3, 4-4

Low potential
Low potential

The proposed drill sites in Areas 3 and 4 are located in an area that is not associated with any physiographic or hydrological features that are associated with archaeological sites (Figure 4).

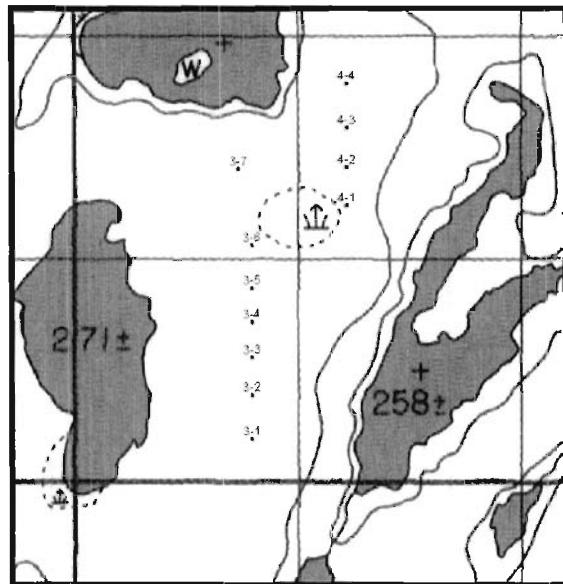

Figure 4. Proposed drill sites Areas 3 and 4

Area 5

Proposed drill sites 5-1, 5-2, 5-3, 5-4 **High potential**

The proposed drill sites in Area 5 are just east of a small lake and stream (Fig 5, 6). This lake system has been identified as a summer and winter travel route by Aboriginal informants from Wawakapewin and Kasabonika First Nations (Figure 5) (Kayahna Tribal Area Council 1985). These distant communities likely were traveling along these routes to and from Lansdowne House, located on

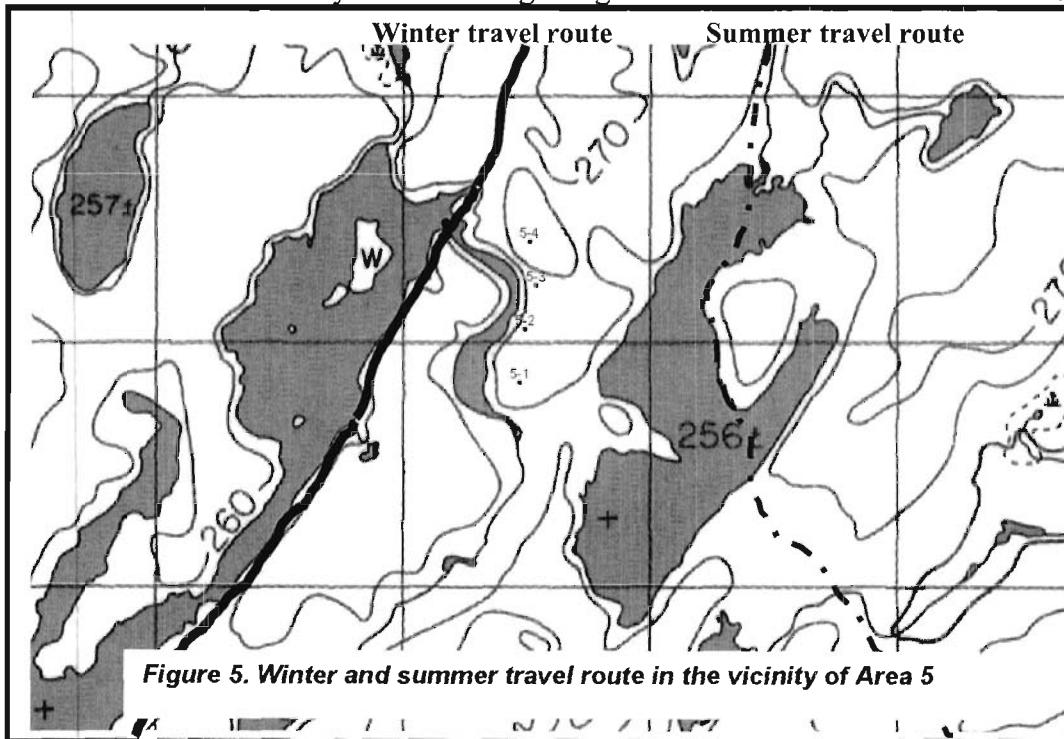

Figure 5. Winter and summer travel route in the vicinity of Area 5

Attawapiskat Lake. However none of the more local communities of Webequie, Nibinamik or Neskantaga First Nations participated in the Kayahna land use study, so their more intensive use of the study area is not represented in this published source.

The drill sites 5-1, 5-2, 5-3 and 5-4 are within 150 meters of the shore of a bay and small stream draining west into the unnamed lake. The proposed drill sites 5-2 and 5-3 are within 30 meters of the rise in elevation and within 50 meters of the stream (Figure 6). The association of these proposed drill sites with the winter travel route, their proximity to the stream and the location of 5-2 and 5-3 next to the break in slope gives this area a high archaeological potential.

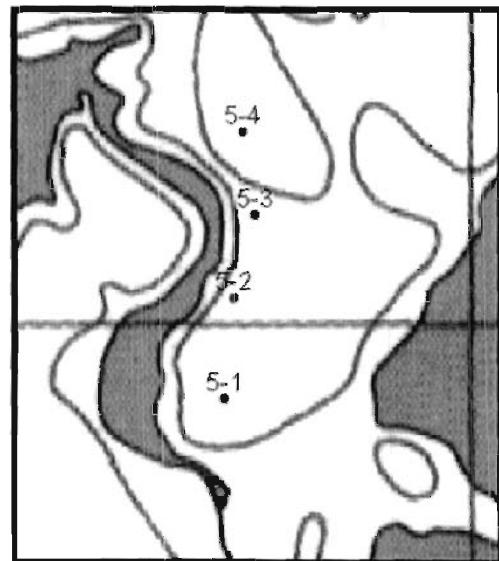

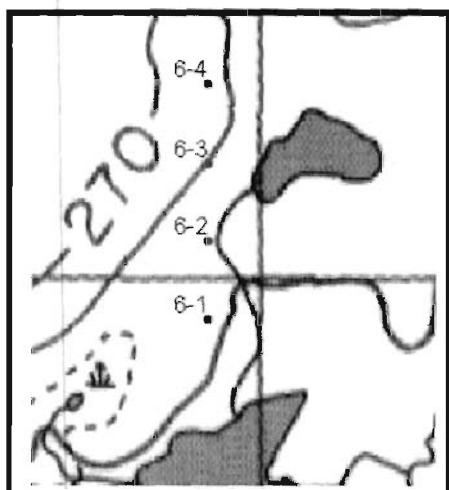

Figure 6. Proposed drill sites Area 5

Area 6

Proposed drill site	6-4	Low-medium potential
Proposed drill site	6-3	Medium potential
Proposed drill site	6-1 and 6-2	High potential

The proposed drill site 6-1 is approximately 60 meters west of a break in slope and within 150 meters of a small stream (Figure 7). The proposed drill site 6-2 is less than 30 meters from a small stream. The proposed drill sites 6-1 and 6-2 therefore are in an area of high archaeological potential.

The proposed drill site 6-3 is located on a break in slope, which is an area of medium archaeological potential. The drill site 6-4 is approximately 50 meters from the break in slope and over 150 meters from the current water body. I have assigned this location low-medium potential since it is just outside of the medium criteria.

Figure 7. Proposed drill sites Area 6

Recommendations

1. Ideally, traditional knowledge should be collected and assessed to supplement the archaeological and map data prior to the start of drilling operations at all of the sites in areas 1 to 6. For the current study area, a community meeting and/or interviews with some key community Elders about activities in the study area would assist in clarifying how the land and resources were used. This would serve to build into the heritage assessment a level of knowledge that currently does not exist.

systemic and detailed collection of the traditional knowledge by Neskantaga First Nation and the surrounding communities should be considered a priority for land and resource management.

2. I would recommend that an archaeologist visit a winter drilling operation to view the process and clarify what, if any impact it might have on archaeological sites. This will be important for determining what actions need to be taken at drill sites that are in all of the levels of potential but particularly those in the medium to high category.

3. In the absence of traditional knowledge about the study area and direct knowledge about the impact of winter drilling the following recommendations are offered regarding the proposed drill sites.

- a) Winter drilling operations can proceed at the drill sites located in low potential areas if the community agrees with the assigned potential for drilling at these sites. This includes drill sites 1-3, 2-2a, 2-2b, 2-3, 2-4; all drill sites in Area 3 and all drill sites in Area 4. This recommendation could be revised in light of additional information regarding traditional knowledge or geomorphic data.
- b) Recommendations for winter drilling operations in low-medium or medium potential will benefit from an archaeologist's review of the winter operations to assess the level of impact to the ground surface. This will allow the archaeologist to determine the level of risk of subsurface damage and thereby refine the recommendations for the low-medium potential areas.
 - a. If it is determined that winter drilling operations has minimal impact³ on the surface and subsurface ground the drill sites in the low-medium potential areas then drilling operations can proceed at locations 1-1, 1-2 and 6-4. If more than minimal impact is observed, it is recommended that the low-medium potential areas be treated similar to the medium potential area (see next).
 - b. Winter drilling operations should not proceed at the drill sites located in the areas medium potential. This includes drill sites 1-4, 1-5, 1-6 and 6-3.
 - Option 1. These drill sites be moved to a low potential area if possible.
 - Option 2. A Stage 2 field assessment occur after the ground has thawed before drilling at these locations.

These recommendations could be revised in light of additional information regarding traditional knowledge or geomorphic data.

- c) Winter drilling operations should not proceed at the drill sites located in the areas identified as having medium-high or high potential. This includes drill sites 2-1, 6-1, 6-2; and all drill sites in Area 5. An archaeologist should conduct a Stage 2 field assessment after the ground has thawed and before drilling activities occurs at these locations. This recommendation could be revised in light of additional information regarding TEK or geomorphic data. The observation of winter drilling operations could also result in the revision of this recommendation.

³ Minimal impact means that the frozen ground surface is not altered in any way at or in the vicinity of the drill sites as a result of operations and that the subsurface impact is limited to the size of the drill hole.

This Stage 1 investigation is intended to provide Superior Diamonds Inc with recommendations regarding the best practices for the protection of archaeological/heritage resources at the thirty proposed drill site locations. Given the limitations of the existing information from which these recommendations were developed and in anticipation of the development of a more substantial database, revisions to these recommendations may be appropriate.

VI. Summary and Recommendations	14

I. Introduction

In February of 2008, Dr. Linda Larcombe (White Spruce Archaeology) was retained by Northern Superior Resources Inc. (formerly Superior Diamonds Inc.) to provide a preliminary Stage 1 heritage impact assessment of the winter drilling operations that are occurring in five areas in the traditional land use area of Neskantaga First Nation (Figure 1).

Thirty potential drill sites in five areas north of Neskantaga First Nation were assessed for archaeological potential based on available mapped information. A phase 1 report was prepared for this preliminary work (see Phase 1 Report) and as a result of this preliminary work it was determined that drill operations in a limited number of locations needed to be relocated out of areas of medium to high archaeological potential. This recommendation was acted upon by Northern Superior Resources Inc and the drill holes in Area 5 were moved to comply with the recommendations. It was also recommended in the Phase 1 Report that an archaeologist views the winter drilling operations at the time of operation and subsequently conducts a post impact assessment in the spring/summer to fully review the process.

Hamilton and Larcombe therefore visited a drill site in Area 2 during in February 2008 and determined that based on the observations that could be made at that time; the winter drill operations would likely have little impact on archaeological sites. These findings are detailed in the Phase 2 Report. It was again recommended that a post impact assessment of Area 5 be conducted in the spring after the drilling was complete and the ground surface was accessible and visible for inspection to confirm that the extent of impact was minimal. Reported here is the current Phase 3 part of the project which focuses on assessing the impact of winter drilling operations on two drill sites in Area 5 (Can-08-16 and Can-08-17) in June of 2008 to complete the stage one portion of this work.

**Figure 1. Study area north of Neskantaga First Nation.
(Map sheet 43D5 Wa pitotem).**

In addition to this primary task, two other areas were assessed for their archaeological potential. The first area is known locally as “Copper Point” on Rowlandson Lake. Some sediment sampling and mineral exploration will begin in this area this summer. Mr. Leo Moonias from Neskantaga First Nation identified this point of land as the location of a number of old camps. Northern Superior Resources Inc. therefore requested a Stage I investigation of this area, which is located in the eastern portion of their claim block. The second area that was assessed is south of Mameigwess Lake on an unnamed lake, east of drill Area 5. In February 2008, Mr. Moonias identified a location at the north end of a small-unnamed lake at the mouth of a small stream/river as an area of significance. This location was visited to investigate the nature of the site with regards to its archaeological potential. Although these locations were not part of the original scope of work for this Stage 1 assessment it was considered prudent to assess these two additional locations for archaeological potential at this time.

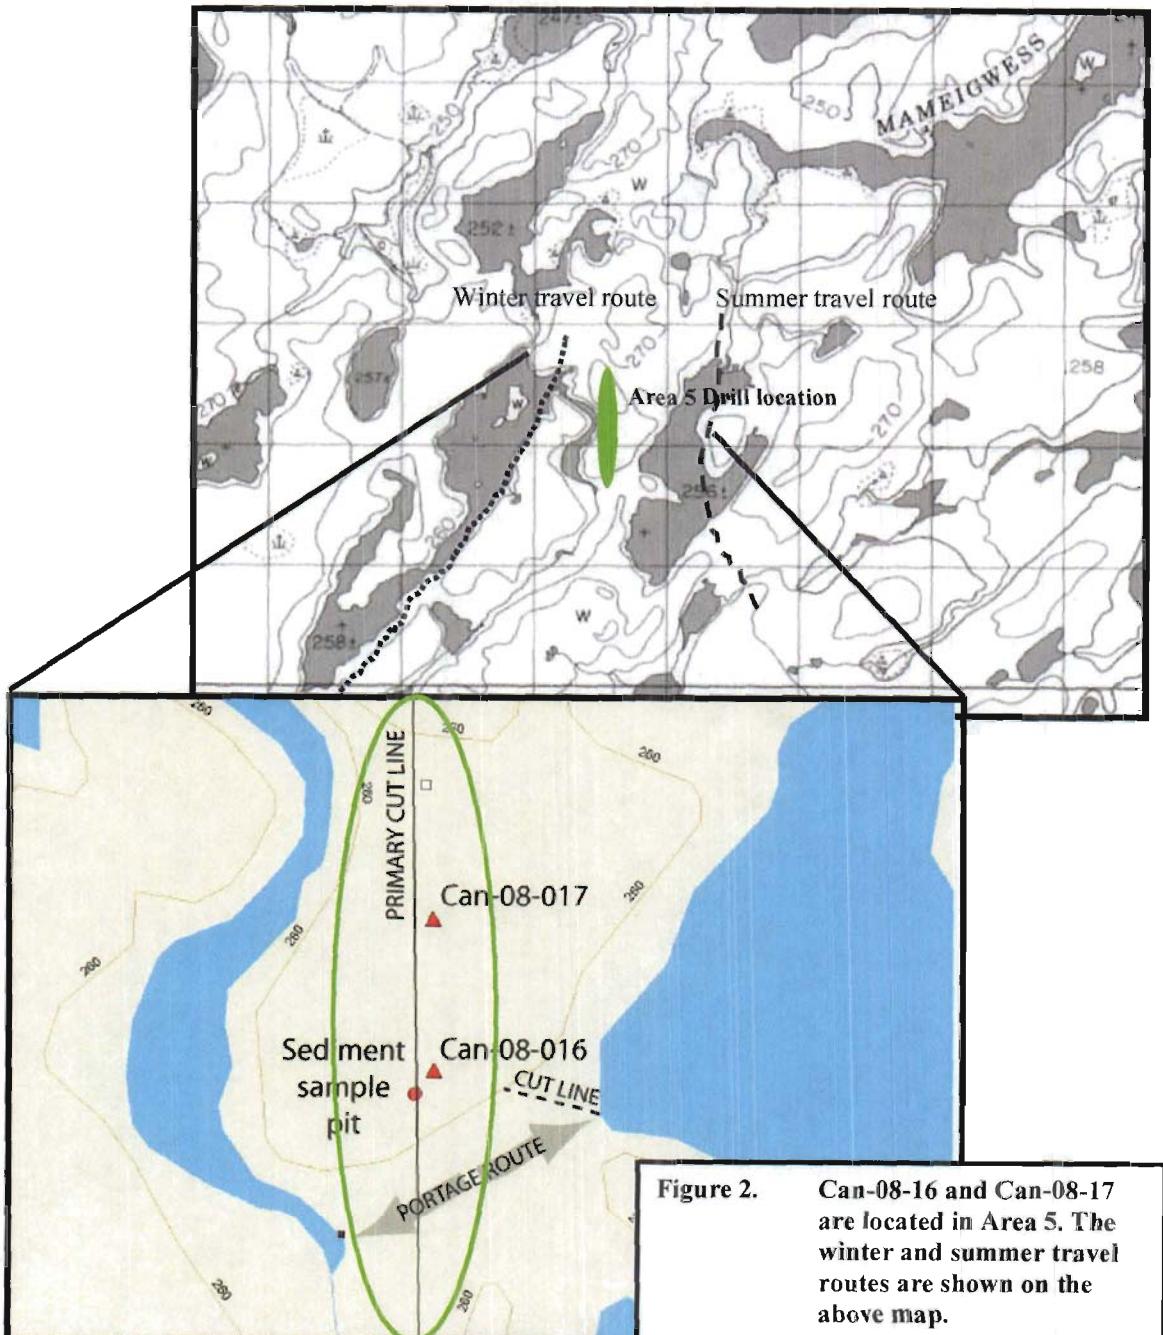

As part of the initial Stage 1 work, it was recommended that more detailed and structured traditional knowledge regarding land use and occupancy should be collected and assessed to supplement the archaeological and map data prior to the start of drilling operations at all of the sites in all areas. A minimal amount of land use information had been collected by Northern Superior Resources Inc. from Mr. Moonias. In addition, some mapped data that had been collected and digitized by Dave Mackett. This information was made available to Dr. Scott Hamilton by Dennis Forbes. For the current study area, a community meeting and/or interviews with some key community Elders about activities in the study area would assist in clarifying how the land and resources are used presently and how they were used within living memory and from oral tradition. This would serve to build into the heritage assessment a level of knowledge that currently does not exist. A systemic and detailed collection of the traditional land use data by Neskantaga First Nation and the surrounding communities should be considered a priority for land and resource management.

All of the above work was conducted with in partnership with Dr. Scott Hamilton (Lakehead University) who has been retained by Neskantaga First Nation to oversee cultural resource management work in their traditional land use area.

II. Post impact assessment of winter drilling operations in Area 5

Area 5 is south of Mameigwess Lake on a ridge between two unnamed water bodies (Figure 2). The Kayahna land use and occupancy study identified a winter and a summer travel route that extend the lengths of these two unnamed water bodies. Furthermore Mr. Moonias had indicated that a portage route exists across the ridge between connecting the eastern most unnamed lake to a small tributary of the western unnamed lake. The location of the drill sites (Can-08-16 and Can-08-17) on this ridge put them in proximity to a medium-high area of archaeological potential and to a documented travel route.

The winter drilling was conducted using the Hydracore gopher drill. The drill which sits on an aluminum table which supports the rig and motor approximately 10-20 cm above the packed snow. Lines were cut through the forest during the winter to access the drill locations and to place water lines from the drill to the closest body of water. The drill sites and the cut lines in this area were visited in June 2008.

1. DH5-1 (Can-08-016) (NAD 83 16U 0443599E 5812083N)

Drill Site DH5-1 was located in a black spruce forest with minimal under storey and a moss base on line (0443598 (NAD 83)). An 11m X 12m area was cleared during the winter (Figure 3). The location of the drill platform on which the Hydracore Gopher drill was clearly visible on the surface of the ground as a result of the clay seepage from the drill operation. The surface of the ground was minimally compressed from the weight of the drill rig and the operators. The core hole (approximately 10 cm in diameter) was flooded. Otherwise, the drilling technique did not disturb any of the subsurface surrounding strata.

Figure 3. Drill site Can-08-16. Area that was beneath the drill platform is slightly compressed.

2. DH5-2 (Can-08-017) (NAD 83 16U 0443599E 5812275N)

Figure 4. Drill site Can-08-17. Log frame used to support the Hydracore Gopher drill.

DH5-2 was located in a mature black spruce forest with no under storey and a sphagnum moss base (Figure 4). A 12 m X 12 m area had been cleared a number of the trees were used to form a log base on which the drill rig had been positioned.

Suspending the platform in this manner over top of the mossy base was likely required to stabilize the drill platform

and it also resulted in less compression of the soils beneath the platform. There was also a small amount of clay seepage from the drilling operation. No subsurface disturbance was noted except for the core hole.

3. Survey lines and water lines

A number of cut lines were identified in Area 5 all of which had been cleared in the winter (Figure 5). The trees and under storey had been cut 20-30cm above the ground surface in the winter along the primary line of sight for the datum line for locating and accessing the drill sites. Secondary lines for the water hoses were visible and we tracked one cut line to the water's edge. The cut lines were inspected in June to assess the extent of surface and subsurface disturbance. The winter clearing activities that are used to construct the primary sight lines and the lines for water access did not result in erosion or disturbance of the surface of sub surface soils along these lines. This activity therefore would have little or no impact on buried archaeological remains.

Figure 5. Primary cut line (0443598E NAD 83)) (top left). Flagged stake at DH5-5 on the primary cut line (top right). Secondary cut line for water access (bottom).

4. Sediment sampling

A sediment sampling test pit was located next to the primary cut line at (16U 044357E 5812054N (NAD 83)). The pit (approx. 30 cm diameter) was dug at an angle into the soil to a depth of approximately 50 cm where the glacial till was exposed (Figure 6). This sampling pit was located on top of the north-south trending height of land between two water bodies. Mr. Moonias had indicated that a travel route (likely a winter route) crossed this height of land from one water body to other. The sampling pit was likely north of the portage route.

If this type of pit were located at an archaeological site it would disturb, artifacts, features and the site integrity. However, in our discussions with Scott Parsons (geologist with Northern Superior Resources Inc.) the priority locations for the sediment sample pits are not associated with eskers or till plains and they are typically dispersed 100 meters (or more) apart. The risk for encountering an archaeological site would be low in this region.

III. Rowlandson Lake

Copper Point is located on a large peninsula on the west side of Rowlandson Lake and is vegetated predominately with black spruce, poplar and red dogwood along the shoreline. Areas of the point were less well drained and had moss cover over standing water. According to the map provided by Mr. Mackett, Mr. Moonias identified the peninsula just to the south of Copper Point as the site of some unspecified types of camps and mining camps in a previous interview (Figure 7). Northern Superior Resources Inc. expressed some interest in exploring this area and were aware that considerable amounts of mining activity had occurred on this point of land in the past.

Figure 6. Sediment sampling pit just off of the primary sight line 0443598E (NAD 83).

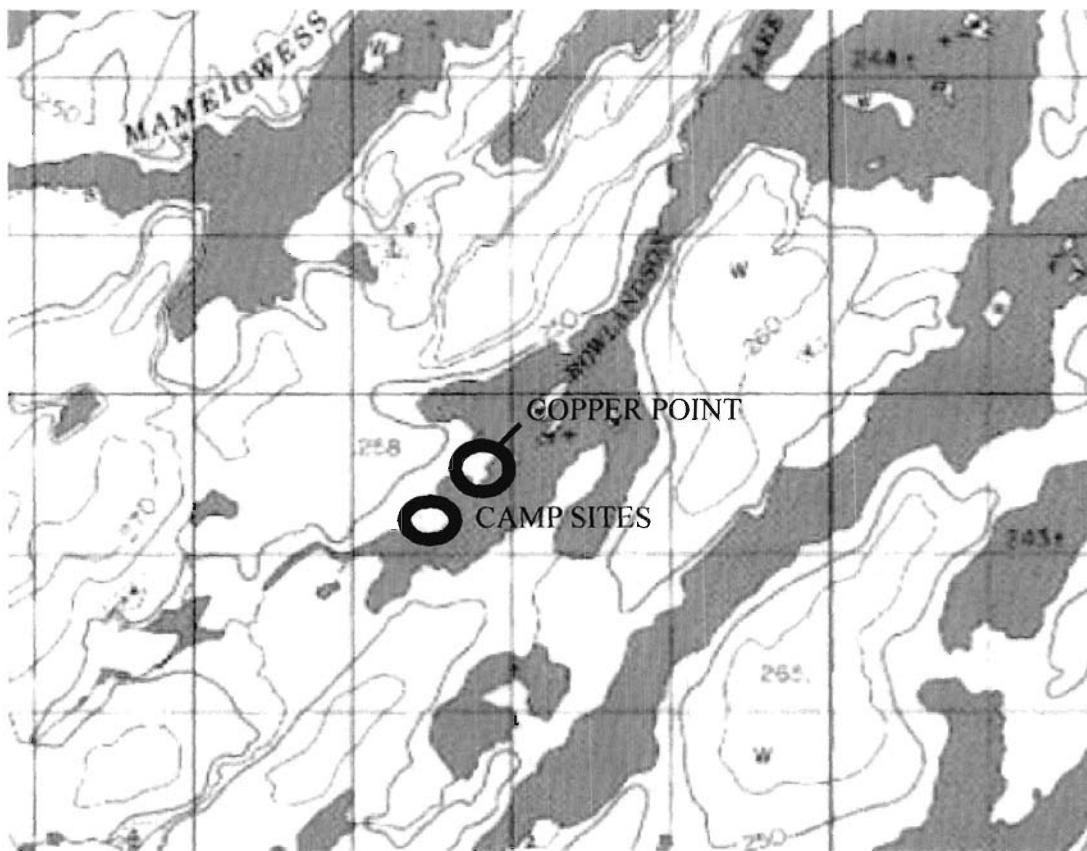

Figure 7. Location of Copper Point and the location identified by Mr. Moonias as the location of several camps.

The area was examined for the presence of archaeological materials using pedestrian survey and shovel test pits. Shovel test pits were each approximately 50 cm square and were excavated to a depth at which glacial deposits were uncovered. The test pits were located away from the mining camp structural features to retain that site integrity and to explore for archaeological remains representing non-industrial land use activities. The structures, geological and mining activity features were measured, photographed and UTM coordinates were recorded using GPS units.

1. Copper Point Mine Site (FcIw-1)

Evidence of the remains of four buildings and tin can middens associated with non-contemporaneous mining camp activities were located on the point of land referred to as Copper Point (Figure 8). The site measures approximately 500m X 200 m.

a. Structure 1 (16 U 0447799E 5812650N (NAD 83))

The remains of a log foundation measuring approximately 6m X 6m was located within 5 meters of the waters edge just northeast of the helicopter landing site (Figure 8 Structure 1).

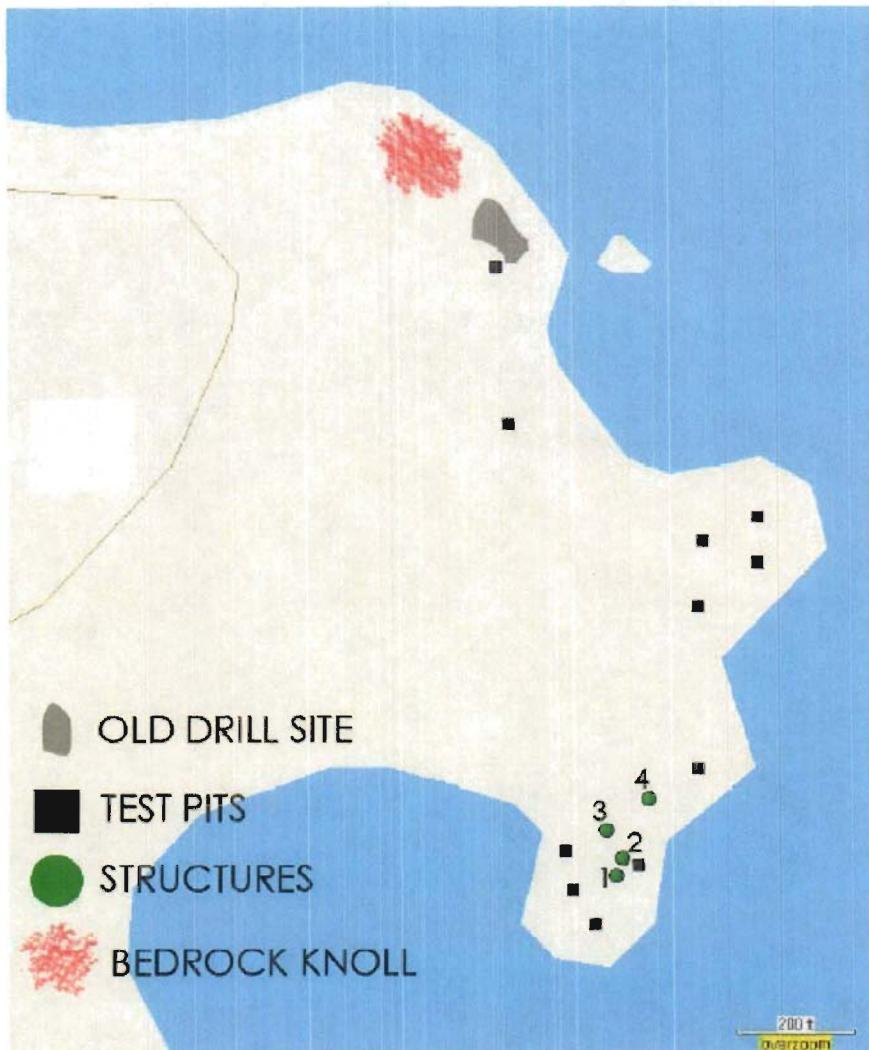

Figure 8. Copper Point Mining Site (FcIw-1) on Rowlandson Lake.

The structure was likely the foundation of a prospecting tent with a canvas top and likely represents one of the older camps at this location (ca. 1940's). Along the south wall of the foundation a square, poured cement block was found underneath a stove pipe with roof flashing (Figure 9). The nails in the flashing were modern-type round nails. A refuse midden of small tin cans was found southeast of this structure, within one meter of the waters edge.

b. Structure 2 (16U 0447789E 5812660N (NAD 83))

Just behind this feature (northwest) was a 5m X 3m structure built into the ground and lined with upright logs (Figure 8 Structure 2). The structure had been built into the ground and soil was mounded on the exterior surfaces of the walls (Figure 10). It appears that the roof of the structure is collapsed. No cultural materials were found in the structure. It is suspected that this structure may have been used as a storage cellar for food.

No cultural refuse was found on the surface of the ground in association with this feature.

Figure 9. South wall of structure 1 (top photo). Looking west. Chimney and cement base on south wall (bottom photo). Looking north.

c. Structure 3 (16U 0447796E 5812684N (NAD83))

The remains of a large building (see Figure 8 Structure 3) were found to the northwest of these first two structural features. The log foundations of structure 3 measured approximately 11m X 11m (Figure 11). Next to the north wall of this structure sections of piping were found. The piping may have functioned to provide radiant heat to the building. Another section of tubing was found in the western portion of the foundation. This camp likely represents the remains

Figure 10. Storage feature built into the ground and constructed with up right logs. Looking west.

Figure 11. Structure 3. Remains of the south foundation. Looking east.

of a more modern (post 1950's) structure. No other cultural materials were found in association with this structure.

d. Structure 4 (16U 0447827E 5812711N)

A small log structure (approximately 2m X 2m) was located to the east of the larger struc-

Figure 12. Structure 4. Remains of a small building. Looking east.

ture 3 (Figure 8 Structure 4 and Figure 12). No debris or refuse were found in association with this feature. The function of this small structure is unknown.

FcIw-1 (Copper Point Mining Site) is comprised of these four structural features that are located within a 200m square area on the point. Shovel test pits were excavated to assess the location for the presence of sub-surface pre-contact components. The test pits were all negative. This site is an example of early industrial mining activities in northwestern Ontario. No artifact materials were found in the test pits in the vicinity of the structures. The site is therefore likely a single cultural component and may be limited to surface materials and the remains of four structures.

This is the first archaeological site recorded within the region covered by the Borden area described by FcIw (a 16 km x 16 km area).

2. Bedrock exposure with copper showing (16U 0447737E 5813026N (NAD 83))

North of the Copper Point Mining Site (FcIw-1) an old drill site was located in the vicinity of a bedrock exposure showing considerable oxidization (Figure 13). This knoll has been exten-

Figure 13. Bedrock exposure with copper showing.

sively investigated for mineral content. Shovel test pits were excavated on the approach to the bedrock exposure and to the northwest. No subsurface remains were recovered. Southwest of this exposure an old drill site was located (0447748E 5812985N (NAD 83)). A cache of drill rods and a core case were found in a cleared area measuring approximately 10m X 10m (Figure 14).

Figure 14. Old drill site. Core casing in the foreground and drill rod in the background.

IV. Portage Route (NAD 27 16U 442945 5812810)

Mr. Moonias had noted that a location on the north shore of a small unnamed lake was a significant area (Figure 15). This location is at the mouth of a small stream (approximately 500m long) which connects to another unnamed lake to the north. These small lakes are connected to Mameigwess Lake through a series of small streams and lakes. This area was probably used quite extensively by peoples from Kassibonica, Wabodin, and Big Trout as a summer portage route or winter corridor between the two small lakes. The area consists of rocky outcrops and a boulder field.

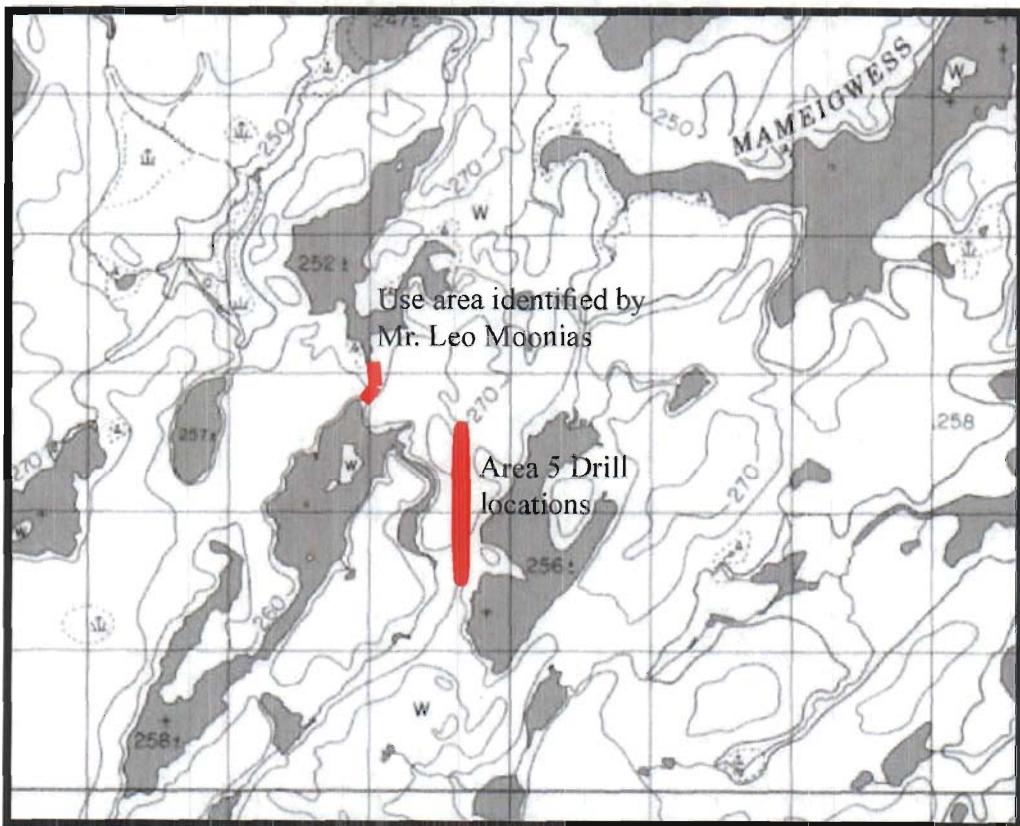

Figure 15. Area of interest identified by Mr. Leo Moonias in relation to drill Area 5

The corridor likely had numerous washouts from high water levels and thus, there is very little surface sediment which would hold any archaeological remains. It was thought there might be remnants of a camp or a small structure at this location however, no evidence of any habitation was found. Considering the environment surrounding the stream (muskeg), it is unlikely a camp would be located within 50m of the stream corridor.

V. Traditional land use study data collection

It was intended that a workshop would be held with five to eight land and resource users and Elders from Neskantaga First Nation to collect land use information for Northern Superior

Resources Inc. claim blocks to the north and west of the community. Our contact person for the workshop was Mr. Alex Ostamas. Mr. Ostamas arrived back in the community on Monday but was unavailable until Tuesday. We spoke briefly to Mr. Ostamas at that time and he told us that there was an important community meeting that afternoon and a workshop would therefore not be possible that day. He suggested that we aim for Thursday for a workshop and that he would contact key community members. Ron Avery introduced Dr. Hamilton and I to Mr. Leo Moonias and we arranged to conduct an interview with him for Wednesday afternoon. Maps had been prepared by Dr. Hamilton so that we could code and mark locations directly onto a series of 1:50,000 maps sheets. The interview was digitally voice recorded. White Spruce Archaeology subsequently digitized the map information that was provided to us by Mr. Moonias at this interview. The originals and the digitized versions of the maps were turned over to Dr. Scott Hamilton who forwarded the information on to Neskantaga First Nation.

VI. Summary and Recommendations

The winter drill operations of Northern Superior Resources Inc. were reviewed in February of 2008 and a post impact assessment was conducted in June. The drilling operations include the clearing of trees and under storey during the winter to construct sight/datum lines, and cores are removed using the portable Hydracore Gopher drill. The drill is positioned on an aluminum frame either directly on the cleared, snow packed ground or positioned on a wood frame which supports it above the ground. The drill is moved between drill sites using a helicopter.

- In light of this assessment it is recommended that no further archaeological investigations are necessary for the winter drill operations in the Northern Superior Resources Inc.'s claim blocks located north of Neskantaga First Nation.

Sediment sampling pits could potentially damage archaeological sites however the locations of these pits are not typically located in areas of medium or high archaeological potential.

- It is recommended that sediment sampling pits be kept well back (20 meters) from the edges of water bodies (streams, rivers, lakes) wherever possible.

The mining camp on Copper Point has been assigned an archaeological site designation and has been assigned a Borden number (Fclw-1). Mining exploration and winter drilling operations will not significantly impact this site.

- It is recommended that no further archaeological work is required for this location at this time.

The traditional land use and occupancy workshop that was anticipated to occur during our week at Neskantaga could not be arranged at that time. A limited amount of information was collected from Mr. Moonias and has been digitized and returned to the community.

- It is recommended that following Mr. Alex Ostamas and Mr. Moonias rec-

ommendations, residents of Summer Beaver be contacted regarding traditional land use and occupancy of the region west of Freure Lake and north of Spero Lake (the western claim blocks).

APPENDICES

Appendix A Laboratory Certificates of Analysis

1.0 INTRODUCTION

Trow Associates Inc. (Trow) was commissioned by Northern Superior Resources Inc. (Northern Superior Resources), to conduct an environmental values inventory in the general vicinity of their diamond drill exploration program, termed the Ti-pa-haa-kaa-ning Gold Project, approximately 30 kilometres north of the Neskantaga First Nation Community, also known as Lansdowne House, Ontario (Figure 1).

The investigation was carried out for due diligence purposes to establish baseline environmental information (i.e. prior to development), post-drilling sampling to determine drill program effects on water quality and First Nation traditional use patterns within the exploration area. This report presents the results of our laboratory program, the findings of our wildlife field investigation and a summary of the First Nation land use inventory.

1.1 Site Description

The centre of exploration is located approximately 30 km northeast of Lansdowne House, Ontario. The location of the property is shown on Figure 2, Drill Site Locations. The exploration site is accessible only by helicopter from the community of Lansdowne House which has a maintained airport.

There is no history of industrial development in the immediate exploration area apart from commercial tourism outpost camps which exist to the north on Mameigwess Lake and to the south-west on Wagabkedei Lake, both of which are outside of the zone of diamond drill exploration (Figure 3). The Ministry of Natural Resources (MNR) has no indication of sensitive areas within the drilling location as indicated through their Natural Resource Values Information System (NRVIS) shown in Figure 3. The values information typically includes natural resource parameters such as sensitive species habitat, bald eagle nests, woodland caribou calving sites, fish spawning locations, and economic development such as commercial camps, trap lines and canoe routes, to name a few.

A winter road right-of-way is situated roughly 9 km south of the exploration area and connects the First Nation Communities at Fort Hope, Lansdowne House and Webequie. The origin of the winter road is off of Highway 599, just north of Pickle Lake, Ontario.

First Nation traditional use, described as fishing, hunting and trapping, occurs throughout the area of exploration. The distribution of these activities is described in more detail in Section 5, First Nation Traditional Land Use. There are no trapper's cabins in the area of interest.

The lands that are presently slated for exploration total an area of approximately 132.8 km² as shown on Figure 2. The general area consists mainly of small lakes, creeks and lowlands, of which many remain unnamed. There is a prominent ground moraine situated immediately to the south-south west of the mining claims, but drilling activity is currently scheduled for the northern part of the claims block.

The most significant drainage feature is the Attawapiskat River, which flows from west to east and located approximately 30 km to the south. Much of the topography can be described as fairly low lying and well vegetated (Photograph 1) as is typical of the Hudson Bay Lowlands.

1.2 General Limitations

This report has been prepared for and is intended for the use of the client, Northern Superior Resources Inc. The contents of this report may not be reproduced in whole or in part, or used or relied upon in whole or in part by any other party for any purpose whatsoever without the expressed written consent of Trow. Any use which another third party makes of this report, or any reliance on or decision made based on it, is the sole responsibility of such third party and Trow accepts no responsibility for any damages of any kind or nature whatsoever, suffered by any other third party as a result of decisions made or actions based upon this report. The findings are relevant for the date(s) of our site visit(s) and should not be relied upon to represent conditions of other dates.

This report is intended to provide "pre-operational and post-operational (completion of drilling)" water quality data for several lakes in and around the area designated for exploration (approximately 30 km northeast of Lansdowne House) as well as important wildlife information, as described herein. It is based on the authorized scope of work of the Environmental Survey proposal by Trow and reported herein. Our conclusions regarding the site are based on observations of existing site conditions and specific chemical analysis. Professional judgement was exercised in gathering and interpreting the information obtained and in the formulation of the conclusions.

Conclusions regarding the condition of the site do not represent a warranty that all areas within the site are of the same quality as those sampled.

Substances could also exist in forms not indicated by the analytical testing conducted. Additionally, the scope of work was based, in part, on rules and regulations that we understand to be current or expected at the time of the work. Changes in regulations, interpretations and/or enforcement policies may occur in the future. Such changes could be reflected in the degree of remediation actually required, if any, at the time of the action.

All reports, field data, notes, laboratory test data, calculations, estimates and other documents which are communicated by Trow to the client or third parties, are instruments of service and will be retained by Trow. These records will be stored in our files for a period of 10 years following submission of the final report, during which time they will be made available to the client, at all reasonable times, for review.

Trow has conducted the services reported herein in a manner consistent with that level of care and skill ordinarily exercised by members of the profession currently practising in the same locality and under similar conditions as this project. No other representation, expressed or implied, is included or intended in this document.

2.0 METHODOLOGY

Prior to the commencement of field work, preliminary discussions and correspondence between Trow (Mr. Randy Wepruk) and Northern Superior Resources (Mr. Ron Avery, P.Geo) confirmed the locations of surface water sampling as well as the logistics of the field work.

In order to assess the “pre-operational” environmental quality of several lakes in the general area of exploration, a water quality sampling program was conducted on February 17, 2008. The field program was carried out under the continuous supervision and direction of Trow field technical staff. Northern Superior Resources made arrangements to provide an assistant, Mr. Rod Sakanee, who is a member of the Neskantaga First Nation Community. Mr. Sakanee is also a local trapper in the area of the exploration drilling.

To facilitate the water sampling and wildlife survey, the client provided access to an Astar AS-350 helicopter. The surface water assessment consisted of the collection of six (6) downgradient and two (2) background surface water samples (Figure 4). The samples were collected by first advancing a hole through the ice, followed by the filling of pre-cleaned bottles provided by the laboratory.

In order to assess the “post-operational (completion of drilling)” environmental quality of lakes as sampled previously, an additional round of water sampling was conducted on June 25, 2008. The field program was carried out under the continuous supervision and direction of Trow field technical staff. Due to open water conditions the sampling methodology was modified to allow for water collection. The samples were collected by lowering a 20 litre food grade plastic pail into the water at the sample sites from a hovering helicopter. Bottles were subsequently filled from the pail, which was rinsed thoroughly with site water before samples were collected.

Surface water samples (including a blind duplicate sample) were sent via courier in a secure cooler under chain of custody to Maxxam Analytics Inc., a CAEAL certified laboratory in Mississauga, Ontario.

The traditional land use activities inventory consisted of pre-flight consultations with Mr. Leo Moonias, a community elder who has spent the majority of his life in the immediate area, and Mr. Sakanee, the local trapper who operates in the exploration sites and adjacent area. It was understood that these two individuals spoke for the entire First Nation Community’s interests. Mapping of the specific traditional activities was accomplished from the air.

Wildlife surveys followed the most recent recommendations from the Ontario Ministry of Natural Resources (MNR) Northwest Science and Information Branch. Transect lines flown west to east and spaced 4 km apart were flown over the study area. It was determined that a raptor nest survey could be accomplished at the same time given the large number of lakes and creeks in the drilling area. First Nation community members participated in the helicopter flights. Several side trips off designated transect lines were undertaken to record specific items that they believed to be of importance. Flights were primarily on February 16, 2008 with final completion on February 18, 2008. To assist with interpretation of the wildlife survey, it is noted that the last snowfall prior to the survey, was on February 11, 2008, four and six days before the transect flights were completed.

3.0 WATER QUALITY

3.1 Surface Water Conditions

The surface waters can generally be described as clear, which is to be expected from an ice covered lake with little to no water movement in the winter months to create turbidity. A similar assessment was made during the follow-up June open water sampling event.

3.2 Water Quality Guideline Selection

For the purposes of this report the surface water analytical results (Table 1) have been referenced to the Provincial Water Quality Objectives (PWQO). However, as water nearest DS608 is currently being sourced for consumption by First Nation members during resource harvesting campaigns, the data are also being referenced to the Ontario Drinking Water Standards (ODWS).

3.3 Water Sample Analytical Results

The results for the surface water samples submitted for analysis are provided on analytical reports in Appendix B and are summarized in Table 1. Note that only the detectable petroleum hydrocarbons and volatile organic compounds appear in Table 1, as all other parameter analysis results were below laboratory detection limits. The reader is referred to Appendix A, which contains the Certificates of Analysis for all parameters tested.

Chemical analyses were conducted by Maxxam Analytics Inc., a CAEAL-certified independent laboratory. Although we have reviewed the results in the context of our expectations, Trow cannot warrant the accuracy of these data.

For QA/QC purposes, Trow collected a blind duplicate sample at BG 1 08 (labelled BG 3 08) during both sampling events for the full surface water parameter list. In general, there is good agreement between duplicate results (i.e. +/- 25%).

Grab sample DS 4 08 experienced field collection difficulties during the February 2008 sampling event in that the entire water column was frozen. Multiple attempts were made to find sufficient water depth to allow a sample to be collected that was not high in sediments, but no such spot could be found. Results of the water analysis reflected the sample taken as demonstrated by elevated levels of turbidity, total suspended solids (TSS), ammonia, aluminum and iron. During the follow-up sampling event in June, 2008 this was not an issue and results better reflected a normal northern Ontario boreal lake with TSS, aluminum and iron below PWQO and ODWS levels.

3.4 Water Quality Discussion

For the purpose of this investigation BG 1 08 and BG 2 08 can be assumed as background. The downgradient results appear to closely resemble background with a few minor fluctuations.

The results of the lake water chemical analyses revealed only minor exceedances of a limited number of surface water (PWQO) criteria. The exceedances of iron and aluminum at three locations are still considered to be normal with respect to typical northern Ontario lakes and do not represent adverse or impacted conditions.

The detection of trace petroleum products trichloroethylene, ethylbenzene and xylenes is not expected, however, the results are two orders of magnitude lower than the PWQO criteria. Possible sources for these compounds are from the gasoline powered ice-auger used to bore through the ice, plastic pale (summer sampling event), helicopter exhaust downwash while sampling from a hover position or lab error. The elevated values of aluminum and iron at DS 4 08 during the February, 2008 sampling event are most likely biased high as a result of high suspended solids (TSS), as the acid preservative added to the water sample in the field would have served to extract more metals than are normally present in the water. This has been confirmed during the June, 2008 summer sampling event as the results more closely match the remaining sampling locations, including background samples.

Comparison of the results from the sample site DS608, where drinking water is collected during camping activities, to the ODWS has revealed two common exceedances, colour (5 TCUs) and hardness (80 to 100 µg/L). Both of these parameters are considered as aesthetic parameters and highly variable among surface water bodies. Surficial geology contributes to both colour and calcium carbonate content, which is also described as hardness. The results do not represent any water quality impact as a result of the exploration drilling activities and, in fact, indicates water quality that can be considered as acceptable potable water.

The overall chemical composition of the various lakes appear to be similar in the area of the undertaking as well as to be closely inline with other northern Ontario boreal lakes. This observation holds true during both winter and summer and indicates that the Northern Superior Resources drilling program of 2007 and 2008 were performed without contributing to any adverse changes in water quality.

4.0 WILDLIFE EVALUATION

4.1 Featured Wildlife Species

The Ministry of Natural Resources (MNR) approach to wildlife management is to designate specific species as the target organisms, along with their required habitat, to guide any activities that are proposed in certain areas. This is particularly useful in the southern parts of Ontario where Sustainable Forest Licences (SFL) are in operation to govern timber harvest and renewal activities. Northern Superior Resources mining claims, north of the Lansdowne House area, do not fall within a SFL.

The drilling location does, however, lie within the area of Ontario designated to be managed for woodland caribou and wolverine (G. Racey, MNR, personal communication). This is important to be aware of due to the habitat management implications that likely would be used to guide large scale industrial development proposals, such as a mine.

4.2 Woodland Caribou Survey

No woodland caribou were seen from the transect survey nor was there any evidence of tracking in the snow cover. There had been four days since the last snowfall prior to the survey date, so had there been any animals within the exploration area they would have left some indication. A reasonable explanation as to why the area was void of caribou sign is addressed below in Section 4.3.

4.3 Wildlife Habitat Description

Habitat management considerations are the primary method of featured species management. Both woodland caribou and wolverine reside primarily in mature forest cover, with sufficient available winter habitat being the most important component. The general area north of Lansdowne House demonstrates a fire-generated ecosystem, which is not all that uncommon in the northern Boreal Forest. (Figure 5, Photograph 2).

The habitat mosaic (different age classes of stands determined by fire history) must continually supply winter requirements. Caribou travel, or migrate, on a seasonal basis to gain access to the specific tract of land that provides the necessary requirements. In this regard, as different fires mature, and new fires burn new areas, the distribution of caribou changes from decade to decade. The time between a fire, and the regeneration of the forest to provide suitable winter habitat in this part of Ontario, would be approximately 60 to 80, or more, years.

The Landsat satellite image of the specific mining claims and exploration sites show that recent fire history has removed most habitat that would be considered suitable as winter habitat for woodland caribou and wolverine. The date of the satellite image is either 1999 or 2000, so the fire event evident in Figures 5 and 6 would suggest that this area burned approximately 20 years ago.

Forest fires are the usual events that cause early succession growth and this young forest regeneration is more suitable for moose as opposed to woodland caribou (Photographs 3 and 4). In a general sense, habitat characteristics that support moose are usually exclusive to woodland caribou, which do not usually use an area as winter habitat for approximately 70 years post fire.

4.4 Nest Survey

Given the recent burn of the exploration area, there were few large trees in which raptors would normally build a nest. The only bald eagle nest that was seen was upon immediate departure from the Lansdowne House airport on Attawapiskat Lake, 30 km away from the mining claims.

4.5 Wildlife and Habitat Discussion

No sensitive species appear in the area, however, an elder related a story of a wolverine sighting several years ago at the north end of Attawapiskat Lake, 15 km south of the mining claims area. Wolverines are far ranging furbearers who maintain a very large home range, so travel through the area would not be an unusual event. Drilling activities should not cause them concern.

Neither woodland caribou nor tracking evidence were seen during the transect flights in February, 2008. This absence may be explained by the relatively recent forest fire that burned most of the exploration area about 20 years ago. As the forest matures, it would be possible to host caribou in the future, but at the moment, the mining claim area does not represent sensitive winter caribou habitat.

Moose densities appear high given that there are several large historic forest fires in the general region.

5.0 FIRST NATION TRADITIONAL LAND USE

5.1 Trapping and Hunting

First Nation consultation began with a general discussion regarding traditional uses within the mining claims and then specific drill site locations. It can be said that there is clear use of the mining claim area by the local community throughout the calendar year. More precise locations of these activities were mapped with two community members on board the Astar helicopter.

Hunting activities are seasonal and include moose, waterfowl and snowshoe hare (Figure 7). It would appear that specific individuals from the community are the major providers of meat. Of interest is the close parallel between the fire distribution in the exploration mining claims and the locations where they indicated that moose hunting was important. Moose hunting areas will change over time as fire disturbs other areas, but at present, the exploration area functions as a relatively close source for moose hunting activities.

The specific drill locations generally fall within some prime hunting locations. The drill sites and line cutting will enhance the hunting arrangements due to forest regeneration in those disturbances.

Two hunting locations are of a more permanent arrangement in that the existing habitat is more stable. Spring waterfowl hunting occurs at a specific location in the northeast section of the claims area (Figure 7). With a combination of spring thaw and marsh (food) lowlands, the area of waterfowl hunting draws a larger group of community members on a consistent basis. This area is also used in the fall to intercept birds migrating south. A traditional camping site is located a short distance to the south of the prime waterfowl hunting spots (Figure 8).

Snowshoe hare hunting occurs in a specific low lying area that is adjacent to a stand of black spruce, which is relatively resilient to fire disturbance. No exploration drilling work is scheduled for this area at this time (Figure 7).

There are no trapping cabins within the exploration area with the closest one belonging to Mr. Rod Sakanee situated to the east of the mining claims. His greatest activity is located to the south west of the drill rig locations but still falls within the group of claims (Figure 7). A small area in the northeast corner of the claims, where the species trapped are beaver and muskrat, is near the drill operations. Most trapping activity for these species of fur bearers is the late fall, when the drill rigs are not operating, so conflicts should be minimal.

5.2 Travel

First Nation Community members travel throughout the exploration area (Figure 9). There are long-established trails, used throughout the year, that provide access to traditional activities like fishing, hunting and trapping. At the moment, there are no drilling activities proposed that would appear to be in conflict with the use of these traditional travel routes.

5.3 Fishing

Lakes within the exploration area provide warm water fisheries, where walleye, whitefish and northern pike represent the target harvest species. There are no trout or salmonid species in the immediate exploration area.

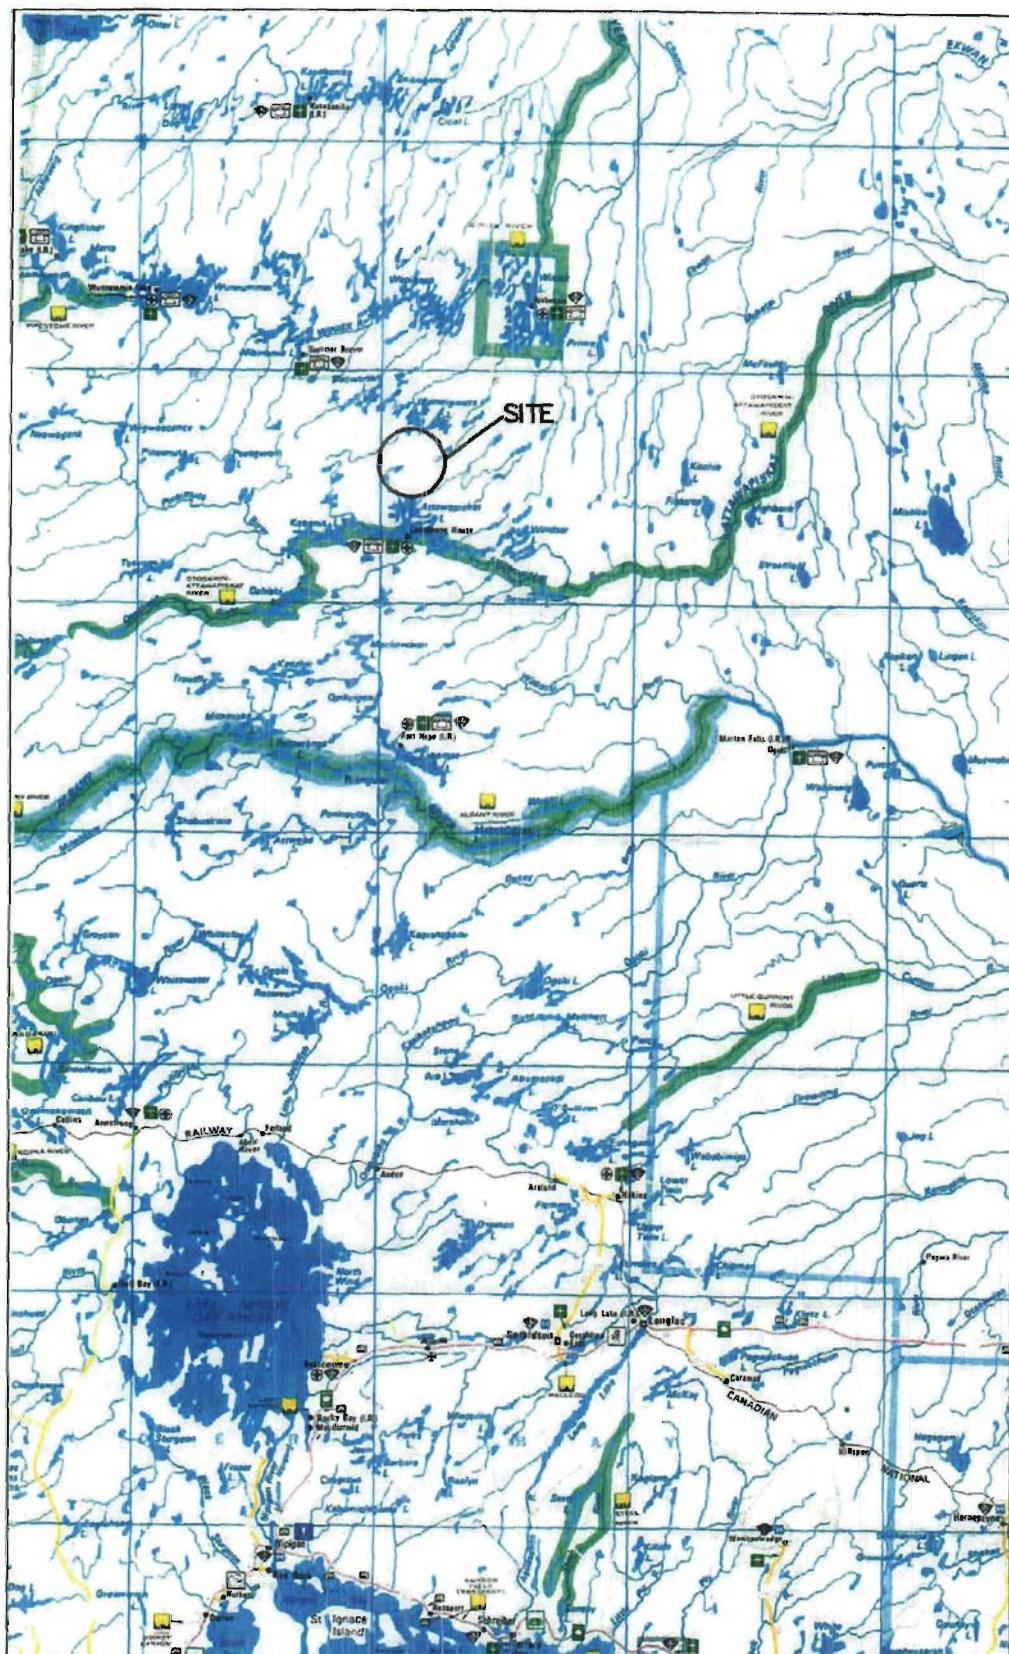

Fishing appears to be an activity of many community members and their entire families (Figure 10). Likely restricted to the open water season, fishing camps are established on lakes that provide the desired fish species (Figure 8). The current drill sites, all operating on land, would not appear to have an affect on any lake ecosystem.

6.0 SUMMARY

Neskantaga First Nation Community has developed many traditional land uses in the general area. They have learned to capitalise on the moose hunting opportunities that result from forest fire activity in the exploration area, but the presence of drilling activity should not compromise their success. Waterfowl hunting and snowshoe hare hunting occur on a seasonal basis but in specific areas not directly associated with current drilling operations. Fishing is a traditional activity that is concentrated in specific lakes throughout the area of exploration.

Water quality exceedances of PWQO and ODWS criteria were very few and relatively minor in both winter (pre-drilling) and summer (post-drilling) sampling events. The exceedances are attributable to either natural conditions or sediment in the samples (winter). The data also show that no exceedances are attributable to the drilling activities. Therefore, the drilling program has had no impact on the water quality.

General Notes for Table 1

1. PWQO: Provincial Water Quality Objectives (PWQO), MOE (updated February 1999). Exceedances indicated in **bold** type face.
 2. ODWS: Ontario Drinking Water Standards (ODWS), MOE (June, 2003). Exceedances indicated underlined type face.
 3. All results are in mg/L unless otherwise stated.
 4. The surface water results of BG 3 08 in Table 1 are a blind duplicate of BG 1 08 (during both sampling events).
 5. DS 4 08 (February results) included lake bottom sediments that may have reacted with acid preservative to dissolve additional metals than would otherwise not be present.
 6. Based on hardness (mean range of 20-150 µg/L) the acceptable concentration of lead was determined using a hardness of 80 µg/L and equalled 0.003 µg/L.

Volatile Organic Compounds in Water	4	N/A	2008/02/21	CAM SOP-00226	EPA 8260 modified

* RPDs calculated using raw data. The rounding of final results may result in the apparent difference.

(1) Values for calculated parameters may not appear to add up due to rounding of raw data and significant figures.

Your Project #: F-08106
Site: LANSDOWNE HOUSE
Your C.O.C. #: 67322-01

=====
Maxxam has procedures in place to guard against improper use of the electronic signature and have the required "signatories", as per section 5.10.2 of ISO/IEC 17025:2005(E), signing the reports. SCC and CAEAL have approved this reporting process and electronic report format.

For Service Group specific validation please refer to the Validation Signature Page

Total cover pages: 2

RDL = Reportable Detection Limit
 QC Batch = Quality Control Batch

Maxxam Job #: A816432
Report Date: 2008/02/27

Trow Associates Inc
Client Project #: F-08106
Project name: LANSDOWNE HOUSE
Sampler Initials:

Package 1	0.7°C
Package 2	1.3°C

Each temperature is the average of up to three cooler temperatures taken at receipt

GENERAL COMMENTS

The BTEX results used for the F1-BTEX calculation were obtained from Headspace-GC analysis.

Sample X25980-01: Chloride, Sulfate and O-phosphate: Due to colour interferences, sample required dilution. Detection limits were adjusted accordingly.

Results relate only to the items tested.

QC Standard = Quality Control Standard
SPIKE = Fortified sample

Validation Signature Page**Maxxam Job #: A816432**

The analytical data and all QC contained in this report were reviewed and validated by the following individual(s).

EWA PRANJIĆ, M.Sc., C.Chem, Scientific Specialist

MEDHAT RISKALLAH, Manager, Hydrocarbon Department

SUZANA POPOVIC, Supervisor, Hydrocarbons

Maxxam has procedures in place to guard against improper use of the electronic signature and have the required "signatories", as per section 5.10.2 of ISO/IEC 17025:2005(E), signing the reports. SCC and CAEAL have approved this reporting process and electronic report format.

Package 1	0.7°C
Package 2	1.0°C
Package 3	0.3°C

Each temperature is the average of up to three cooler temperatures taken at receipt

GENERAL COMMENTS**F1-BTEX Analysis.**

The BTEX results used for the F1-BTEX calculation were obtained from Headspace-GC analysis.

Results relate only to the items tested.

NC = Non-calculable

RPD = Relative Percent Difference

QC Standard = Quality Control Standard

'PIKE = Fortified sample

1) The recovery in the matrix spike was not calculated (NC). Because of the high concentration of this analyte in the parent sample, the relative difference between the spiked and unspiked concentrations is not sufficiently significant to permit a reliable recovery calculation.

Validation Signature Page**Maxxam Job #: A869534**

The analytical data and all QC contained in this report were reviewed and validated by the following individual(s).

MAMDOUH SALIB, Analyst, Hydrocarbons

TROY CARRIERE, B.Sc., C.Chem, Scientific Specialist

MEDHAT RISKALLAH, Manager, Hydrocarbon Department

Maxxam has procedures in place to guard against improper use of the electronic signature and have the required "signatories", as per section 5.10.2 of ISO/IEC 17025:2005(E), signing the reports. SCC and CAEAL have approved this reporting process and electronic report format.

Vinyl Chloride	ug/L	<0.2	0.2	1550881

 RDL = Reportable Detection Limit
 QC Batch = Quality Control Batch

Maxxam Job #: A869534
 Report Date: 2008/07/08

Trow Associates Inc
 Client Project #: F-08106
 Project name: LANSDOWNE HOUSE

VOLATILE ORGANICS BY GC/MS (WATER)

Maxxam ID		Z58310		
		2008/06/25		
	Units	DS408	RDL	QC Batch
p+m-Xylene	ug/L	<0.1	0.1	1550881
o-Xylene	ug/L	<0.1	0.1	1550881
Xylene (Total)	ug/L	<0.1	0.1	1550881
Surrogate Recovery (%)				
4-Bromofluorobenzene	%	91		1550881
D4-1,2-Dichloroethane	%	104		1550881
D8-Toluene	%	100		1550881

RDL = Reportable Detection Limit
 QC Batch = Quality Control Batch

Maxxam Job #: A869534
Report Date: 2008/07/08

Trow Associates Inc
Client Project #: F-08106
Project name: LANSDOWNE HOUSE

Package 1	0.7°C
Package 2	1.0°C
Package 3	0.3°C

Each temperature is the average of up to three cooler temperatures taken at receipt

GENERAL COMMENTS

F1-BTEX Analysis.

The BTEX results used for the F1-BTEX calculation were obtained from Headspace-GC analysis.

QC Batch	Parameter	Date	Matrix Spike		Spiked Blank		Method Blank		RPD		QC Standard	
			% Recovery	QC Limits	% Recovery	QC Limits	Value	Units	Value (%)	QC Limits	% Recovery	QC Limits
1554124	Total Copper (Cu)	2008/07/07	92	80 - 120	110	80 - 117	<1	ug/L				
1554124	Total Iron (Fe)	2008/07/07	94	80 - 120	114	80 - 120	<100	ug/L				
1554124	Total Lead (Pb)	2008/07/07	100	80 - 120	107	80 - 120	<0.5	ug/L				
1554124	Total Magnesium (Mg)	2008/07/07	NC(1)	80 - 120	114	80 - 120	<50	ug/L				
1554124	Total Manganese (Mn)	2008/07/07	96	80 - 120	111	80 - 120	<2	ug/L				
1554124	Total Molybdenum (Mo)	2008/07/07	107	80 - 120	110	82 - 117	1, RDL=1	ug/L	9.8	25		
1554124	Total Nickel (Ni)	2008/07/07	94	80 - 120	111	81 - 117	<1	ug/L				
1554124	Total Potassium (K)	2008/07/07	97	75 - 125	109	75 - 125	<200	ug/L	8.2	25		
1554124	Total Selenium (Se)	2008/07/07	102	75 - 125	114	82 - 118	<2	ug/L				
1554124	Total Silicon (Si)	2008/07/07	88	75 - 125	102	67 - 140	<50	ug/L				
1554124	Total Silver (Ag)	2008/07/07	100	80 - 120	111	80 - 120	<0.1	ug/L				
1554124	Total Sodium (Na)	2008/07/07	NC(1)	75 - 125	106	75 - 125	<100	ug/L				
1554124	Total Thallium (Tl)	2008/07/07	102	80 - 120	108	80 - 129	0.05, RDL=0.05	ug/L				
1554124	Total Tungsten (W)	2008/07/07	106	75 - 125	105	81 - 123	<1	ug/L				
1554124	Total Uranium (U)	2008/07/07	109	80 - 120	108	82 - 120	<0.1	ug/L				
1554124	Total Vanadium (V)	2008/07/07	101	80 - 120	113	82 - 118	<1	ug/L				
1554124	Total Zinc (Zn)	2008/07/07	97	80 - 120	113	80 - 120	<5	ug/L				
1554124	Total Zirconium (Zr)	2008/07/07	110	75 - 125	110	84 - 118	<1	ug/L				
1554373	Mercury (Hg)	2008/07/07	105	75 - 125	106	84 - 113	<0.1	ug/L	NC	25		

N/A = Not Applicable

NC = Non-calculable

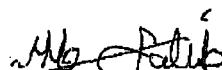

RDL = Reportable Detection Limit

RPD = Relative Percent Difference

(1) - The recovery in the matrix spike was not calculated (NC). Because of the high concentration of this analyte in the parent sample, the relative difference between the spiked and unspiked concentrations is not sufficiently significant to permit a reliable recovery calculation.

Validation Signature Page**Maxxam Job #: A869534**

The analytical data and all QC contained in this report were reviewed and validated by the following individual(s).

MAMDOUH SALIB, Analyst, Hydrocarbons

TROY CARRIER, B.Sc., C.Chem, Scientific Specialist

MEDHAT RISKALLAH, Manager, Hydrocarbon Department

Maxxam has procedures in place to guard against improper use of the electronic signature and have the required "signatories", as per section 5.10.2 of ISO/IEC 17025:2005(E), signing the reports. SCC and CAEAL have approved this reporting process and electronic report format.
