SUMMARY

The Nemegosenda Lake Property (the Property) consists of seven patented mining parcels and 21 unpatented mining claims in Chewett, Collins and McGee Township, Porcupine Mining District, Ontario, Canada. The seven-patented parcels total 757.559 Hectares in area. The 21 unpatented claims total 2960.3 Hectares in area (total for the Property is 3718.06 Hectares).

The Property lies approximately 19 miles (30 kilometres) northeast of the community of Chapleau via Highway 101. The Property can be accessed via Nemegosenda Road that intersects Highway 101, and then via secondary or tertiary bush roads approximately 8 kilometres north of Highway 101.

The Property occupies the northeast corner of the Nemegosenda Lake Alkalic Complex (the Complex), which lies within the Kapuskasing Sub-province of the Superior Province of the Canadian Shield. The Complex is approximately circular and 6 kilometres in diameter. It consists predominantly of alkaline silicate rocks. Gneisses dominate the surrounding regional area.

In 2008, Sarissa purchased the Nemegosenda project and instituted a literature search and re-plot of all relevant data available in historic records. Sarissa subsequently retained an independent consultant to prepare a compliant 43-101 report in July of 2009, in which further exploration work, including diamond drilling, was recommended.

Niobium mineralization is the principal mineral of economic interest found within the Complex. Elevated rare earth elements and tantalum are also found, however the concentrations of these elements can be quite erratic. The historical exploration work of Dominion Gulf and the recent exploration work of Sarissa Resources have been focused on two areas of the Complex with significant niobium concentrations referred to as the Hawke (formerly the "D") and Southeast Zones. These zones are found in the northeast quadrant of the Complex.

Sarissa undertook a 2-hole diamond-drilling program from January 2010 to February 2010 to test the niobium mineralization occurring within the Southeast Zone. In particular, hole 83-10 was located to test the extreme southern portion of magnetic anomalies associated with the Southeast Zone that have yet to be drilled. Hole 81-10 was spotted to test the niobium results obtained in Dominion holes #33 and #35 in the central portion of the Southeast Zone.

The results of 81-10 show a high degree of reproducibility in niobium values compared to holes #33 and #35. This data provides further support of the reproducibility of niobium grades outlined by the historical of the Dominion work over the Southeast Zone.

Hole 83-10 intersected a high-grade zone of niobium from 182 to 285.5 metres down hole that returned 0.31% Nb₂O₅ over 103.5 metres. This result extends the known strike length of the Southeast zone approximately 300 metres further south from the previously known limit, and lends weight to the potential of the Southeast Zone to host substantial reserves of niobium.

The 2010 diamond drilling also confirmed that the Southeast Zone is host to anomalous values of Rare Earth Elements and tantalum, however the economic potential for these elements warrants additional investigation.

Further diamond drilling of the Southeast Zone is recommended to confirm and expand on the potential resource here. Prior to undertaking further work, a well cut, surveyed grid system with GPS stations taken at all turn-off points along the baselines should be established over the Southeast Zone. A north-south baseline orientation is recommended and should extend to the southern boundary of claim 20619 MG. If a cut grid is established, then consideration should be given to conducting a detailed total field magnetic ground survey.

INTRODUCTION AND TERMS OF REFERENCE

This report on the Sarissa Resources Inc. (Sarissa) Nemegosenda Alkaline Complex Property has been prepared generally following the standards outlined in National Instrument Policy 43-101 for the Canadian Securities Administration.

Mr. Warren Hawkins, P.Eng is the Exploration Manager for Sarissa. Mr. Hawkins, a qualified person under NI 43-101, has visited the property on numerous occasions over the past several months. Mr. Hawkins supervised the drilling work outlined in this report. The author is a Professional Engineer with over 15 years of mineral exploration experience.

The terms of reference for this report are to report the results of the diamond drilling work undertaken by Sarissa in January and February 2010 at the Nemegosenda Alkaline Complex Property (the Property) and to make recommendations for further work based on these drilling results.

PROPERTY DESCRIPTION AND ACCESS

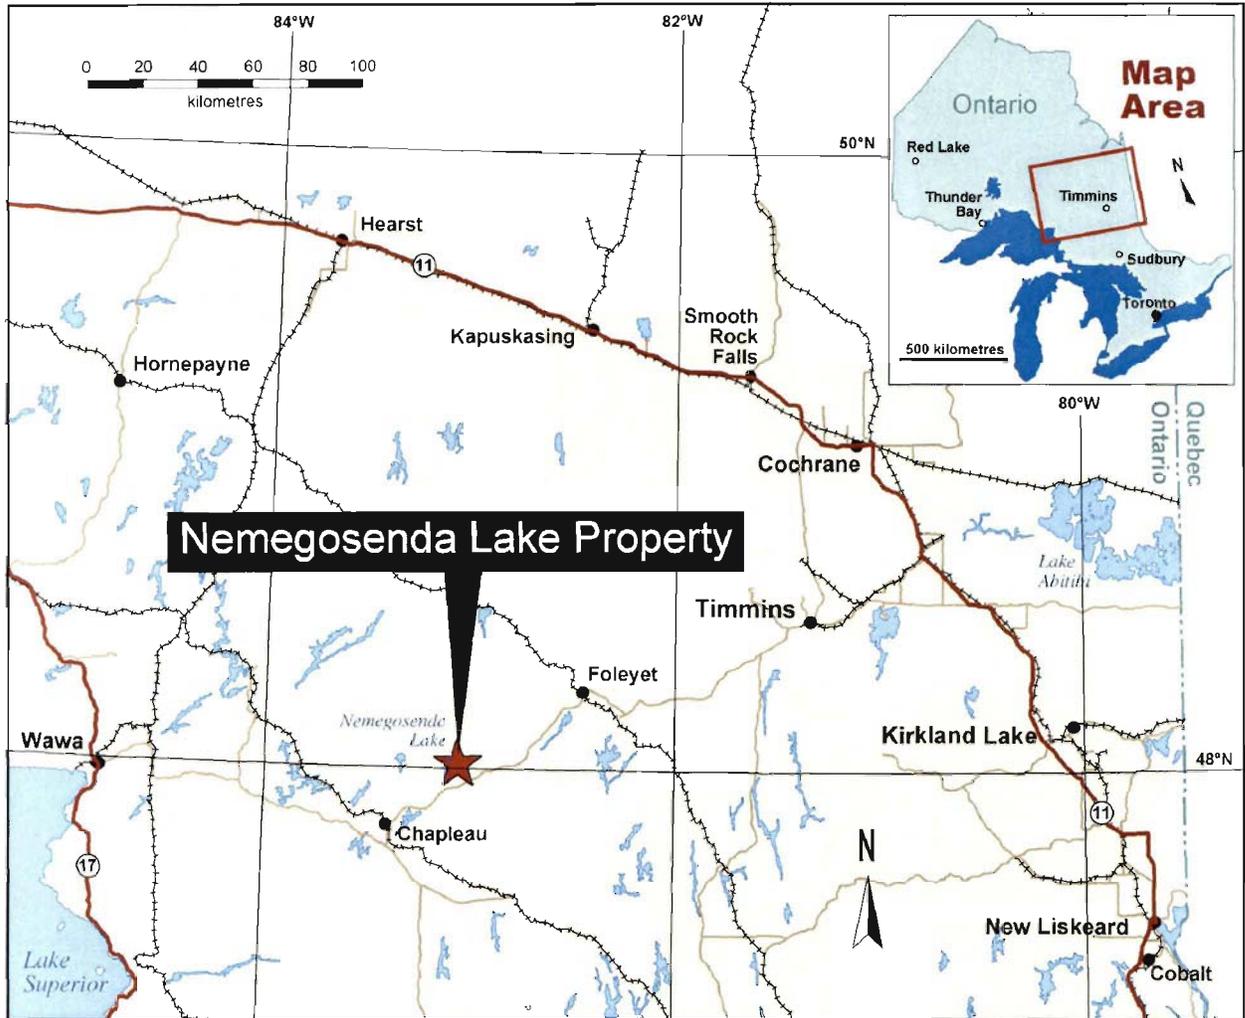

Property Status

The Nemegosenda Lake Property consists of seven patented mining parcels and 21 unpatented mining claims in Chewett, Collins and McGee Township, Porcupine Mining District, Ontario, Canada. The seven-patented parcels total 757.559 Hectares in area. The 21 unpatented claims total 2960.3 Hectares in area (total for the Property is 3718.06 Hectares). Chewett is an organized Township; therefore the patented mining claims have been surveyed and are described in Lots and Concessions. Collins is an unorganized Township and has no Lots or Concessions; hence the patented mining claims are designated with numbers. Table 1 provides a list of the mining claims that comprise the property.

Figure 1
 Sarissa Resources Inc.
 Nemegosenda Lake Property
 Northeastern Ontario
Location Map

The Universal Transverse Mercator (UTM) NAD 83, Zone 17 co-ordinates for the centre of the property is approximately 345000 E and 5329000 N.

According to records provided by Sarissa management, Sarissa owns 100% of the claims comprising the Property

Accessibility, Climate, Local Resources and Infrastructure

The property lies approximately 19 miles (30 kilometres) northeast of the community of Chapleau via Highway 101. The property can be accessed via Nemegosenda Road that intersects Highway 101, and

then via secondary or tertiary bush roads approximately 8 kilometres north of Highway 101. The complex is found along the east-shore of Nemegosenda Lake.

The most convenient access to the property is via boat from the lodge at the southwest corner of the property, or using all-terrain vehicles along logging roads. Much of the logging roads have now been overgrown with vegetation and/or blocked with beaver dams making access via four wheel drive truck difficult at this time. At present there are no facilities or infrastructure (railroads or hydro lines) at the property.

The Dominion Gulf adit is found along the east shoreline of Nemegosenda Lake, and is presently covered by a metal gate.

Physiography

The property relief can be described as gently rolling. Bedrock outcroppings are generally scarce, and are generally found along the shoreline of Nemegosenda Lake. There is a steep slope along the east shoreline of the Nemegosenda, within the property boundary. Areas within the property not already logged are covered with dense stands of cedar, birch, juniper, pine and alder brushes. The field season generally extends from May to November, depending on snowfall.

GEOLOGICAL SETTING OF THE NEMEGOSENDA COMPLEX

The Property occupies the northeast corner of the Nemegosenda Lake Alkalic Complex, which lies within the Kapuskasing Sub-province of the Superior Province of the Canadian Shield. This sub-province is a northeast striking horst consisting of rocks metamorphosed to upper amphibole to granulite facies rank. Faulting associated with this regional structure likely controlled the location of the Nemegosenda Lake Alkalic Rock Complex (the Complex).

The Complex is approximately circular and 6 kilometres in diameter. It consists predominantly of alkaline silicate rocks. Gneisses dominate the surrounding regional area. There is no evidence of other intrusive masses in the surrounding area except similar carbonate-alkaline complexes, possibly some gabbro, and diabase dikes.

Detailed geological information for the complex is limited to parts of the north and east flanks where historical diamond drilling was concentrated. The remaining portion of the complex is generally described based on surface mapping and interpretation of geophysical surveys.

The alkaline complex may be divided into two main units, the syenite core and the metasomatic aureole. The syenite core is approximately 5 kilometres in diameter. It is composed of a number of distinct rock types that are leucocratic and differ in texture and in their proportions of alkali feldspars, nepheline, biotite, and soda pyroxene and amphibole.

The rocks of the metasomatic aureole may be divided into three groups; the syenite core contact zone, surrounded by the pyroxenitic zone, and the red alkaline fenite zone on the outside.

The red alkaline fenites are the oldest rocks present. They are found on the north and adjoining parts of the west and east flanks adjacent to the fenitic/metasomatically altered gneisses. They mark a zone of hydration and oxidation.

The pyroxenitic zone consists of crystalline pyroxene-rich rocks and represents a zone of dehydration and reduction. The pyroxene is either superimposed on the red alkaline fenites, or with orthoclase, forms a rheomorphic type occupying openings in, or replacing, fractured and brecciated fenitic rocks.

The syenite contact zone represents the transition from the fenitized rocks of the metasomatic aureole to the granitoid-textured rocks of the syenite core. Towards the core, this zone shows a marked increase in alkali feldspar, biotite, and nepheline, and a marked decrease in soda pyroxene and pyrochlore.

Intersecting the rocks of the metasomatic aureole there is a wide range of rock types occupying and replacing breccia zones. These zones are chiefly composed of magnetite, apatite, biotite, alkali feldspar, and calcite, with one or two of these minerals dominating particular parts of a breccia zone. Specific types of these rocks have been called jacupirangite, biotite-feldspar pegmatites, and sovites.

Carbonate veins and late mafic dikes cut all rock types.

Aeromagnetic data indicates that the general regional trend of the gneissic country rocks is northeast. Near the alkaline area, the strike of the rocks tends to parallel the rim of the complex and dip inward.

Foliation in the fenitized rocks encircles the intrusive core and dips steeply inward. Breccia zones with varying types of mineralization such as the jacupirangites, biotite-feldspar pegmatites, and the sovitic rocks, are also found along linear zones or masses elongated parallel to the circular outline of the complex. There is also some evidence of ring-like magnetic zones in the intrusive core. One drill hole determined that these rings are due to magnetite in fractured and brecciated zones.

The magnetic data indicate several faults cutting and shifting, in particular the rocks of the metasomatic aureole. Generally the magnetic strength and pattern are distinctly different across these magnetic interruptions, indicating vertical movement with a change of rock types.

Niobium mineralization is the principal mineral of economic interest found within the Complex. Elevated rare earth elements and tantalum are found within the complex, however the concentrations of these elements can be quite erratic. The historical exploration work of Dominion Gulf and the recent exploration work of Sarissa Resources have been focused on two areas of the complex with significant niobium concentrations referred to as the Hawke (formerly the "D") and Southeast Zones. These zones are found in the northeast quadrant of the Complex. Niobium mineralization in these zones is found predominantly within the fenitized rocks of the outer margin of the metasomatic aureole. These zones are associated with magnetic highs as outlined in the historical airborne and ground geophysical surveys completed by Dominion Gulf.

SUMMARY OF PREVIOUS EXPLORATION AND DEVELOPMENT WORK

Dominion Gulf Company completed an aeromagnetic survey over the area in 1954 in which a large anomaly was identified. Staking was begun in February 1955, and a total of 196 claims were staked.

Subsequently, detailed geological and ground magnetic surveys were completed. Initial prospecting and mapping in the area proved the presence of alkaline rocks that were radioactive and locally contained appreciable amounts of niobium. By the fall of 1956, 68 holes had been completed totalling 35,306 feet of diamond drilling. Drilling was concentrated in two main areas of high magnetic response, the 'D' Zone (now known as the Hawk Zone) and the 'Southeast' Zone. These zones are located in pyroxenitic and malignitic rocks that are found along the margin of the complex. Limited exploration work was done on the remaining area of the complex. In 1958, an adit was driven 580 feet in the D Zone to obtain a bulk sample for metallurgical extractions tests, which reached the pilot-plant stage in 1959.

According to the available historical reports downloaded from the Ontario Ministry of Natural Resources Assessment File database, there is no evidence of staking or prospecting in the area prior to Dominion Gulf's activities in 1955.

The ground magnetic data proved valuable in the historical exploration work at the Property, particularly in identifying trends of the higher-grade niobium bearing zones in the Southeast Zone. In particular, Dominion drill hole #35 intersected 0.32% niobium over a considerable width. This drill hole intersects a magnetic anomaly and therefore highlights the importance to drill testing other anomalies within the Southeast Zone.

G.E. Parsons, a noted geologist specializing in alkaline complexes in the Superior region of Canada, supervised the exploration work and prepared numerous reports summarizing the fieldwork of Dominion Gulf in the in the late 1950's and early 1960's. Based on the work completed by 1961, Parsons calculated a mineralized reserve of some 20 million tons grading 0.47% Nb₂O₅ for the D Zone. These reports are currently available for review through the Ontario Ministry of Mines and Northern Development database and are referenced in this report.

Approximately 2,900 metres of drilling was completed on the Southeast Zone, in which highly anomalous niobium, yttrium and rare earth elements concentrations were detected by semi-quantitative analyses.

In 1987, Musto Explorations Ltd. (Musto) undertook exploration work that concentrated on the Southeast Zone as they were investigating the reported occurrence of rare earth concentrations in this area of the complex. Musto re-assayed several holes from the Southeast Zone stored on the Property, the results of which confirmed the results obtained during 1955/1956 programs. Musto also completed 475 metres of trenching in 12 separate areas of the Southeast Zone to sample and confirm the near surface exposure of niobium in the area.

In 1991, Placer Exploration competed re-plotting of the D and Southeast Zones. In 2008, Sarissa purchased the Nemegosenda project and instituted a literature search and re-plot of all relevant data available in historic records. This work lead to the drilling of a 14-hole confirmation series of drill holes within the D Zone. Sarissa subsequently retained an independent consulting firm to prepare a compliant 43-101 report in July of 2009, in which further exploration work, including diamond drilling, was recommended for both the D and Southeast Zones.

Work By Government Agencies or Academic Agencies

R. P. Sage, as part of an Ontario Geological Survey project begun in 1974 to study alkalic rock complexes in Ontario, produced a report entitled "Geology of Carbonatite – Alkalic Rock Complexes in Ontario: Nemegosenda Lake Alkalic Rock Complex – District of Sudbury, 1987". This report provided detailed geological analysis of the Nemegosenda Complex based on the work of Dominion Gulf/Parsons and on detailed field mapping that Sage himself completed. The OGS report included detailed petrographic and geochemical analyses. The fieldwork and interpretations of Parsons were largely confirmed by the detailed work of Sage and the OGS.

OGS geochemical analyses included major and trace element analyses of whole-rock samples, normative minerals (CIPW and alkalic) for whole rock samples, and average chemical compositions of lithological units. Ninety-six samples were collected from outcroppings along the edge of Nemegosenda Lake (both on and off of Sarissa's property), and from Dominion Gulf drill cores. As expected, many of these samples were elevated in niobium (up to 6,000 parts per million in a core sample collected from the D Zone). Of particular note, four core samples from Zone D, the Breccia Complex and Zone G were elevated (up to 0.5%) in rare earth's lanthanum (La), neodymium (Nd) and cerium (Ce). Analyses for uranium and tantalum were not performed in the OGS study.

WINTER 2010 DIAMOND DRILLING WORK

Sarissa undertook a 2-hole diamond-drilling program from January 2010 to February 2010 to test the niobium mineralization occurring within the Southeast Zone on the Property. In particular, hole 83-10 was located to test the extreme southern portion of the ground magnetic anomalies associated with the Southeast Zone that have yet to be drilled. Hole 81-10 was spotted to test the niobium results obtained in Dominion holes #33 and #35 from the central portion of the Southeast Zone. Hole 82-10 has yet to be drilled as it was intended as a second twinning of holes #33 and #35, however upon review of the 81-10 results it was determined to be not necessary. Sarissa intends to drill Hole 82-10 in another location at a future date.

The two holes totalled 646 metres of which all was assayed. Both holes were drilled at an inclination of -45 degrees. 81-10 was drilled at an azimuth of 110 degrees to a depth of 230 metres and was collared at (UTM co-ordinates Zone 17) easting 345588 and northing 5319012. 83-10 was drilling at an azimuth of 45 degrees to a depth of 416 metres and was collared at easting 345565 and northing 5318355. 81-10 is located within patented claim 20534 MG, and 83-10 is located within patented claim 20619 MG.

The results of 81-10 show a high degree of reproducibility in niobium values compared to holes #33 and #35. This data provides further support of the reproducibility of niobium grades outlined by Dominion Gulf and Musto Exploration over the Southeast Zone, and the reserve estimate of the independent consultant which estimated 20 million tons grading 0.35% Nb₂O₅.

Hole 83-10 intersected a high-grade zone of niobium from 182 to 285.5 metres down hole that returned 0.31% Nb₂O₅ over 103.5 metres. This result extends the known strike length of the Southeast zone an estimated 300 metres south from the previously known limit, and lends weight to the conclusion of July 2009 43-101 independent consultant's report that the Southeast Zone has the potential to host substantial reserves of niobium.

The author, Mr. Warren Hawkins, spotted the drill hole collars for this program. Mr. Hawkins also completed the logging of the core.

SAMPLE METHOD AND APPROACH

Quality Control and Assurance for all sampling during the 2010 winter diamond drilling program by Sarissa was under the direction of Mr. Warren Hawkins, P.Eng, Geological Engineer and Exploration Manager for Sarissa. Core samples were collected from the drill site and transported back to a secure core shack onsite. Mr. Hawkins logged each core box, noting rock types and alteration. The core was then halved by diamond saw with the sample half packaged in sealed heavy weight polyethylene bags, and scintillometer readings taken and recorded.

Sarissa geological consultants delivered core samples to Swastika Laboratories of Swastika, Ontario and AGAT Laboratories of Mississauga, Ontario. Samples sent to Swastika Laboratories were crushed and prepared for testing, and forwarded for analyses to Assayers Canada of Vancouver, B.C. Samples sent to AGAT Laboratories were processed entirely onsite.

SECURITY

From the time the samples are cut in the core shack where one half of the core is taken, bagged, tagged and sealed with security seals, a Chain of custody form and Lab Requisition sheet is filled out on every forty samples sent in to the Lab for analyses. The sample are placed in larger sugar bags and subsequently sealed with security seals and shipped by one of the company's personnel directly to the Lab's receiving dock whereupon samples are counted, catalogued and documentation given. The procedure (requisition) slip is included with each batch of samples and the lab processes these in the order of receipt. At the time of receipt, the samples are kept in a locked secured area until they can be processed and once analysis is completed the pulps and rejects for each sample is kept separately in a dry, secure area for return to the client. Most labs are bonded and carry insurance in cases of fire and theft. Each sample has an identifier number and can be located within hours if the client requires further analysis or reproducibility by another lab for backup.

DATA VERIFICATION

Alternating duplicate and blank samples were inserted into the sample split core sample series every 10 samples. A review of the duplicate and blank analytical results showed minimal variation from the expected result. In addition, laboratories undertook repeat analyses of pulp from random samples from each sample batch. A review of these analyses also showed good reproducibility.

INTERPRETATIONS AND CONCLUSIONS

The results of the winter 2010 program have yielded the following conclusions:

- A high degree of reproducibility in niobium values was obtained between the historical niobium values of the Dominion Gulf and Musto Exploration and the results obtained by Sarissa over the Southeast zone.

- Drilling results have extended the known area of niobium mineralization for the Southeast zone a further 300 metres to the south of the previous known limit.
- There is now substantial reason to believe that independent preliminary resource estimate for the Southeast Zone of 20 million tons grading 0.35% Nb₂O₅ can be substantially increased.
- The Southeast Zone is host to anomalous values of various Rare Earth Elements and tantalum, however the economic potential for these elements warrants additional investigation.

RECOMMENDATIONS

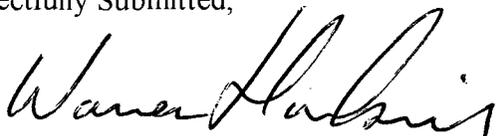

Further diamond drilling of the Southeast Zone is recommended to confirm and expand on the potential resource here. Prior to undertaking further work, a well cut, surveyed grid system with GPS stations taken at all turn-off points along the baselines should be established over the Southeast Zone. A north-south baseline orientation is recommended and should extend to the southern boundary of claim no. 20619 MG.

There is an untested magnetic high at the south end claim no. 20619 MG in which further diamond drilling is warranted.

In particular, diamond drilling should be systematically along the established grid system, with 45 degree angled “cross-over” to confirm historic drill results and to aid in determining dip of the geological formations here.

If a cut grid is established, consideration should be given to conducting a detailed total field magnetic ground survey as the data from the previous ground survey is more than 50 years old. Readings should be collected over 25 metre intervals, and a base station set up to correct for diurnal variations.

Respectfully Submitted,

Warren Hawkins, P.Eng

STATEMENT OF QUALIFICATIONS

I, Warren Hawkins, of 33 University Ave #1307, Toronto, Ontario, do hereby certify that:

I have been a registered professional engineer with Professional Engineers Ontario since September 1991.

I am a graduate of the University of Waterloo with a BAsC in Geological Engineering, 1989.

I have worked in the exploration industry in various technical capacities since 1982, and as a Geological Engineer from April 1989 until September 1994, and from April 2005 until the present.

I am the author of this report on the Nemegosenda Lake Property located near Chapleau, Ontario, researched assessment and related data and supervised the diamond drilling work at the Nemegosenda Lake property in January and February 2010.

I am not aware of any material fact or material change related to this report that is not reflected in the technical report.

Dated in Toronto, this 12 Day of July, 2010

A handwritten signature in black ink that reads "Warren Hawkins". The signature is written in a cursive style with a large, looping initial 'W'.

Property Name:	NEMEGOSENDA Property	Grid Coordinates:	N/A	Core Stored At:	Chewett Twp. Core Shack
Locality Name:	Southeast Zone, Chewett Twp., Ont.	East:	N/A	Logged By:	W. Hawkins (logged Jan.31-Feb.4 2010)
Claim #:	20619 MG	North:	N/A	Drilled By:	L. Salo of Shinning Tree Ont.
Hole #:	83-10	Bearing:	N 45 degrees E	Acid Test EOH:	-42 degree
UTM:	Zone 17	Inclination:	-45 degrees	Sample Type:	Split Core - Diamond Saw
Easting (m):	345565	Proposed Length:	200 m	Drill Start:	Jan. 11, 2010
Northing (m):	5318355	Total Length:	416 m	Drill Finish:	Jan.22, 2010
Elevation:	390 m	Core Size:	NQ	Page:	1 of 9

Notes: DDH 83-10; 93 boxes of core; Amph - amphibole, Bt - biotite, Carb. = carbonate Cc - calcite, Chl - chlorite, Cpx - chalcopyrite, Ep - epidote, Fspar - feldspar, Hem - hematite, specular Hem - metallic hematite as opposed to brick red powdery looking hematite, Kspar - potassium feldspar, Mt - magnetite, Plag - plagioclase, Pyx - pyrite, Qtz - quartz, Ser - sericite; DTCA - Degrees To Core Axis; cps = counts per second (GR-135 scintillometer)
