**REPORT ON THE SURFACE WORK AND DRILLING CAMPAIGN  
ON THE MATACHEWAN PROPERTY,  
ALEXANDRIA MINERALS CORP.  
CAIRO TOWNSHIP, ONTARIO**

**For:**

ALEXANDRIA MINERALS CORP.

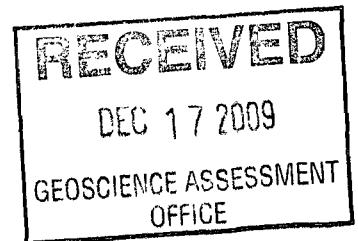

**Prepared By:**

Geneviève Boudrias, Geo, MSc.

Dr. Eric Owens, PGeo, PhD

Val-d'Or, October 20<sup>th</sup>, 2009

## SUMMARY

---

At the request of Dr. Eric Owens, President of Alexandria Minerals Corp and Mr. Eddy Canova, Vice-President of ALEXANDRIA MINERALS COPORATION ('Alexandria'), I was given the mandate to prepare a report on the January – March 2008 Drilling Campaign on the Matachewan Property, Province of Ontario, Canada.

Alexandria Minerals Corporation ("Alexandria") is a public Ontario registered company trading under the symbol "AZX" on the Toronto Venture Exchange (TSX) and on the Frankfurt Stock Exchange (symbol: "A9D") with corporate offices located at 100 Adelaide St. W, Suite 405, Toronto, Ont., M5H 1S3.

The Matachewan gold exploration property is located east of the town of Matachewan in the Matachewan Mining Camp, Ontario, Canada. The property is located 3 km east of two (2) past-producing gold mines, the Young-Davidson Mine and the Matachewan Consolidated Mine, which together produced 0.96 million ounces of gold at an average grade of 0.1 oz/t Au. Northgate Minerals Corporation has recently been actively building a new ore deposit at the Young-Davidson site, which now hosts Proven and Probable Reserves of 2.8 million ounces of gold, principally hosted in altered and deformed syenite, an important rock type in the location of gold deposits along the Kirkland Lake to Matachewan stretch of the Cadillac-Larder Lake Break.

Alexandria's property is located within the Abitibi Greenstone Belt, a prolific gold and base metal producer known for such mining camps as Timmins (Ont.), Kirkland Lake (Ont.), Noranda (Qc), Val-d'Or (Qc), and Chibougamau (Qc). The Abitibi is of Archean age, comprised primarily of metavolcanic and metasedimentary rocks intruded by mafic to felsic plutonic and hypabyssal dykes and batholiths. Shear zones and faults, significant in the localization of gold deposits, developed extensively during the geologic history of the Abitibi Belt. One of these, the Larder Lake – Cadillac Break, crosses the region in the Kirkland Lake and Matachewan camps, near which numerous gold deposits occur.

The Matachewan property is underlain principally by metavolcanic and sedimentary rocks and mafic to felsic intrusive rocks of Archean age and Proterozoic diabase dykes. The most prominent geologic feature in the region is the Larder Lake and Cadillac Break (LLCB) crossing the property in ENE direction.

Past exploration work on Alexandria's property indicates that alteration consists of green carbonate in mafic volcanics and red-orange potassic, hematitic, silicified, pyritized and fine quartz vein alteration in syenites, alteration styles that are comparable to that found at the Young-Davidson gold deposit. Furthermore, alteration and deformation is widespread on the property, extending a minimum of 0.5 kilometer north of the break. Historic exploration activities on the Carmax Property have included mapping, geochemical surveys, geophysics (Mag, IP), trenching and twelve (12) previously drilled holes. One of the WMC Company drill holes drilled west of the Carmax property confirms the presence of the LLCB shear zone north of the highway and at depth.

The 2008 diamond drilling program consisted in the drilling of three (3) holes (MAT08-06, MAT08-08 and MAT08-09) totalling 1,621.0 meters of NQ core. The drilling program commenced in January 2008 and was completed on March 2008. The purpose of these drill holes was to test strong IP chargeability anomalies and low Mag anomalies.

## **1.0 INTRODUCTION**

The Matachewan Property is located in the Matachewan gold mining camp, in the Province of Ontario, Canada (Figure 1). Alexandria Minerals Corp. has entered into an option agreement to explore and earn 50% ownership in the mineral rights of the Carmax property. This portion of Alexandria's property is located five (5) kilometers east of two (2) mines with historic combined production of 0.9 million ounces of gold, the Young-Davidson and Matachewan Consolidated mines. These mines are the subject of extensive work by Northgate Minerals Corporation, whose Young Davidson project now hosts Proven and Probable Reserves of 2.8 million ounces of gold.

From January 2008 to March 2008, Alexandria Minerals Corporation carried out a 1,621.0 meters drilling program by drilling three (3) holes located on three (3) separate claims (Figure 2 and Table 1). The drilling tested three (3) distinct geophysical targets (IP Chargeability anomalies) (Figure 5). This report summarizes the drilling program and its salient features.

## **2.0 DISCLAIMER**

The author referred to part of the Drill report "Drill report on the Matachewan Property, Cairo Township, Ontario" written by Mr. Eric Owens, 2005.

One of the authors has visited the property.

## **3.0 PROPERTY DESCRIPTION AND LOCATION**

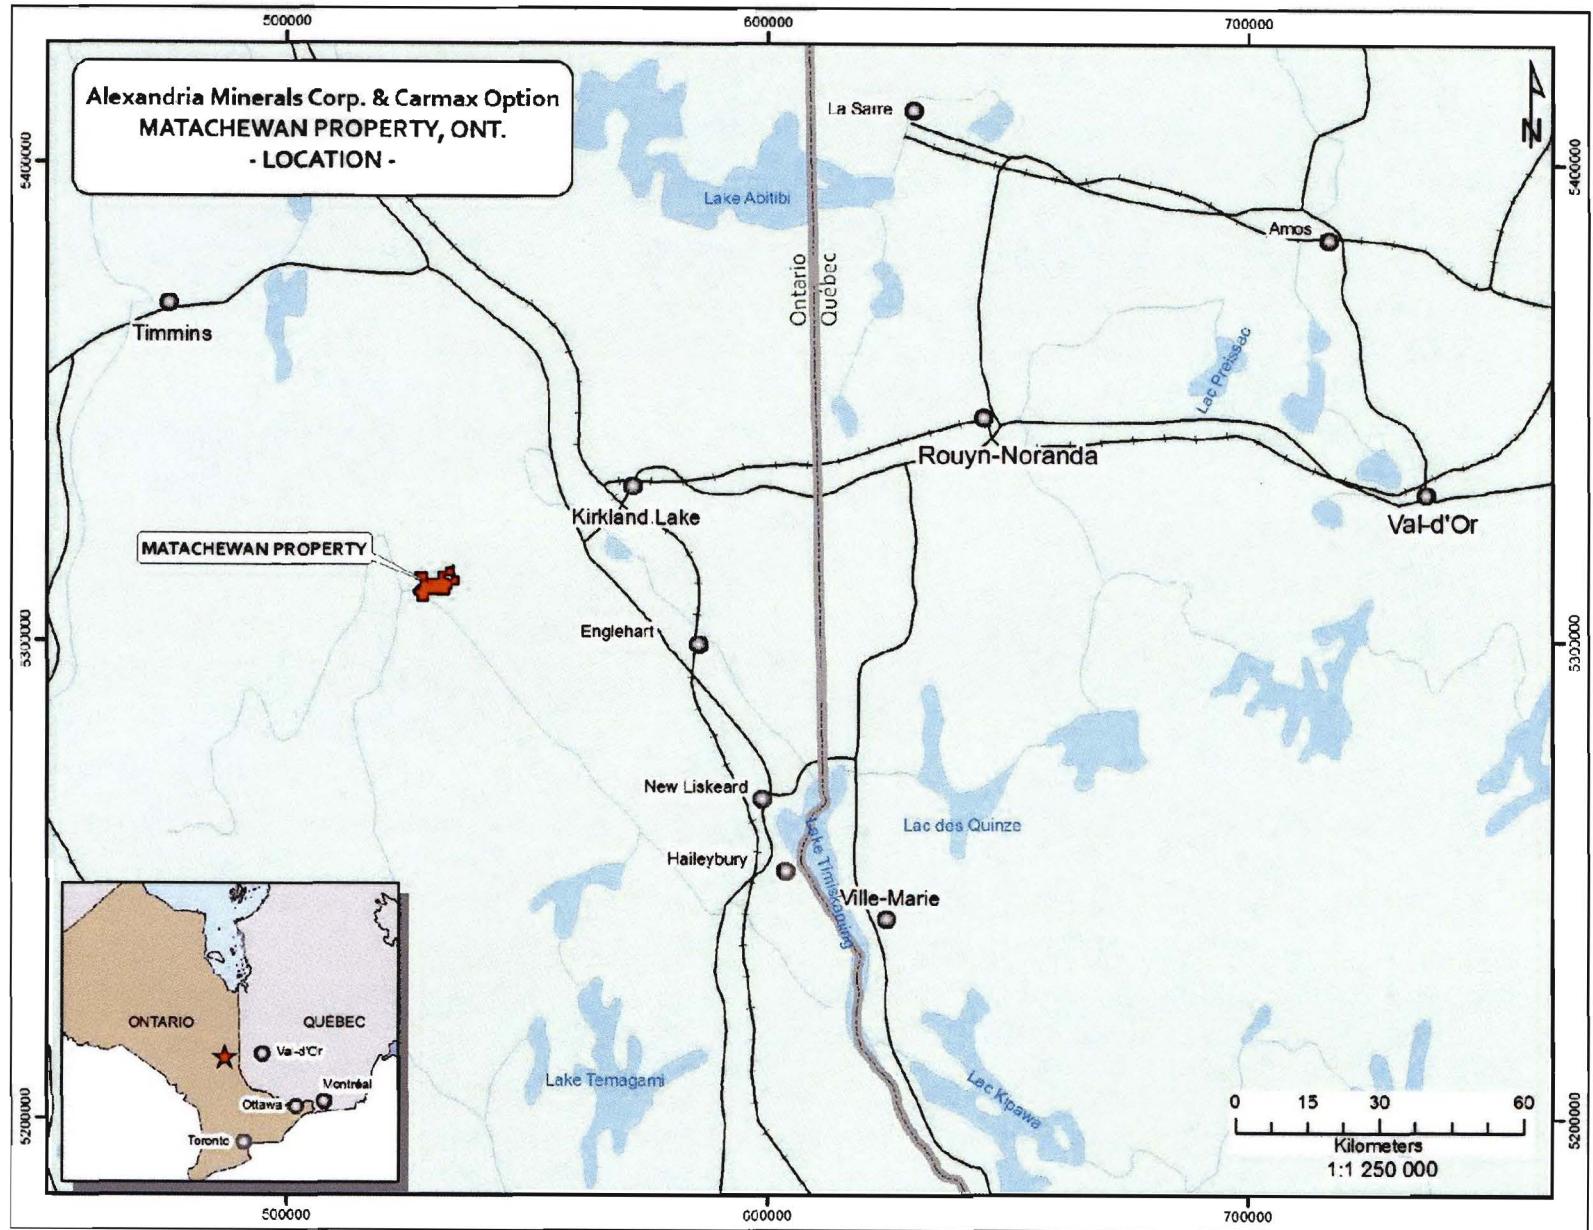

### **3.1 Property Location**

The property is in the Southern part of the Cairo Township in the mining district of Temiscaming, province of Ontario. The center of the property is located at 80°37'W and 47°55'N, a distance of 1.5 kilometers east of the town of Matachewan, Ontario (Figure 2). The property is covered by the NTS Sheet 41P/15 at a scale of 1: 50,000. The property borders the east side of the town of Matachewan and is further bounded on the west and south by the Montreal River.

### **3.2 Claims Status**

The property consists of thirty-five (35) Mining Titles owned by Alexandria. All the claims are in good standing (Figure 2 and Table 1) and verified on the web site of the Ministry of Northern Development and Mine ([http://www.mci.mndm.gov.on.ca/Claims/Cf\\_Claims/clm\\_clr.cfm](http://www.mci.mndm.gov.on.ca/Claims/Cf_Claims/clm_clr.cfm)) (Verified on July 6<sup>th</sup> 2009).

## **4.0 ACCESSIBILITY, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE AND PHYSIOGRAPHY**

### **4.1 Accessibility**

The infrastructure and accessibility is excellent as it is located on the east side of Matachewan, a community with a long mining tradition, and is bisected by Highway 66. Access to the Matachewan property from Toronto is made via HWY 11 to Kirkland Lake, then west 40 kilometers along HWY 66. There are regular flights into Timmins from Toronto several times daily, and Matachewan is a one and a half hour drive from the Timmins airport.

### **4.2 Climate**

The summer season stretches from May to October with temperatures in the pleasant 15 to 30° C range. Ideal ice conditions for winter drilling in the area are normally from early or mid January to the end of March.

### **4.3 Local Resources, Infrastructure and Physiography**

Any service requirements for field assistance can easily be obtained from the towns of Matachewan, Kirkland Lake and Timmins, Ontario. Such services as accommodations, field equipment, contractors (line cutting, geophysics and drilling) and technicians are available on a short notice. Custom milling in the area is also available at a number of producing mines in the Kirkland Lake area.

The property is bound on the west and south sides by the Montreal River. The topography on land is rolling with relief of 50 meters or less. Outcrop exposure in the area is good. The property has seven (7) small lakes and is dissected by the Whiskyjack creek on the east side and the Montreal River on the west and central parts of the property. A forest of jack pine, white pine, spruce, poplar and birch cover the property except where bog and muskeg exists.

Permitting for drilling or for mining is favorable due to the long history of mining in the area.

## **5.0 HISTORY**

This section is from the 2005 Owens report.

Exploration and production for gold has been carried out in the area for years and continues to be important. The areas with the most activity have been in the Kirkland Lake area along the CLLB or along parallel structures north of the break, through the syenite intrusives, and along splays off of these structures.

The Matachewan area has had a history of mineral exploration and prospecting going back to 1916. The Young-Davidson was discovered in 1916 by Jack Davidson and the Matachewan Consolidated was discovered shortly after by Sam Otisse. After intensive sampling of the Young-Davidson Property, production commenced in 1934 at a rate of 500 tons per day. The mine was shut in 1956, having mined 6,128,272 tons of ore containing 585,690 oz of Au (0.10 oz / t Au) and 132,000 oz of Ag. The Matachewan Consolidated mines started production in 1934 at a rate of 85 tons per day.

The mine was shut in 1954 with 3,535,200 tons of ore mined containing 370,427 oz of Au (0.11 oz/t Au) and 133,710 oz of Ag. Recent exploration and metallurgical work has been carried out at the Young Davidson and Matachewan Consolidated mines in an effort to determine the feasibility of bringing them back into production. The Stancorp Mine located just 300 meters west of HWY 566, and 5 kilometers west of the Matachewan property, has several pits and trenches along mineralized quartz veins within syenites cutting Timiskaming sedimentary rocks. Assays run as high as 0.52 oz/ton Au and 1.08 oz/ton Ag.

Several gold mines in the Kirkland Lake district have operated since the early 1900's producing millions of ounces of gold along the same LLCB.

In 1995, WMC carried out a drilling program to confirm the presence of the LLCB structure. Three (3) holes were drilled and one (1) of the holes (95-3) intersected a 21 meters wide, highly altered, carbonatized and fuchsite altered section of the break with more than 5% fine pyrite. A mineralized quartz vein of 0.05 meter with pyrite, chalcopyrite and galena assayed 9.70 g/t Au. Shortly after, WMC dropped the ground.

In 2005, between October 6 and October 16, Alexandria carried out, a diamond drilling program of 754.4 meters with five (5) drill holes. The holes were located on five (5) separate IP geophysical targets and associated shear zones. A number of weak anomalous gold and silver values were obtained along some of these shear structures and weak signatures of VMS type mineralization was observed at a basalt and rhyolite contact.

The drilling was performed by Forage M Lafrenier Inc. from Nedelec (Temiskami), Quebec with two (2) – twelve (12) hour shifts, drilling 754.4 meters in eleven (11) days with one down day and ten (10) actual drill days. The technician on site supporting the drilling program was Sylvain Brousseau from Service Exploration.

## 6.0 GEOLOGICAL SETTING

The geological section is taking from the Owens, 2005 report.

### 6.1 Regional Geology

The Matachewan property is in the south central part of the Abitibi Belt in the Canadian Shield (Figure 3). The Abitibi Belt consists, in general, of Archean supracrustal sequences of volcanic rocks and interbedded sedimentary rocks, intruded by plutonic rocks. The volcanic-sedimentary sequences occur in four principal depositional cycles, each cycle of which begins with komatiitic (high magnesium) or tholeiitic volcanic activity.

This activity is followed by volcanic cycle evolution to more intermediate and felsic volcanism. Furthermore, there is an evolution from tholeiitic-dominant volcanic activity in the earlier cycles evolving to calc-alkaline and alkaline dominant magmatic activity in later cycles.

Figure 3. Regional Geology.

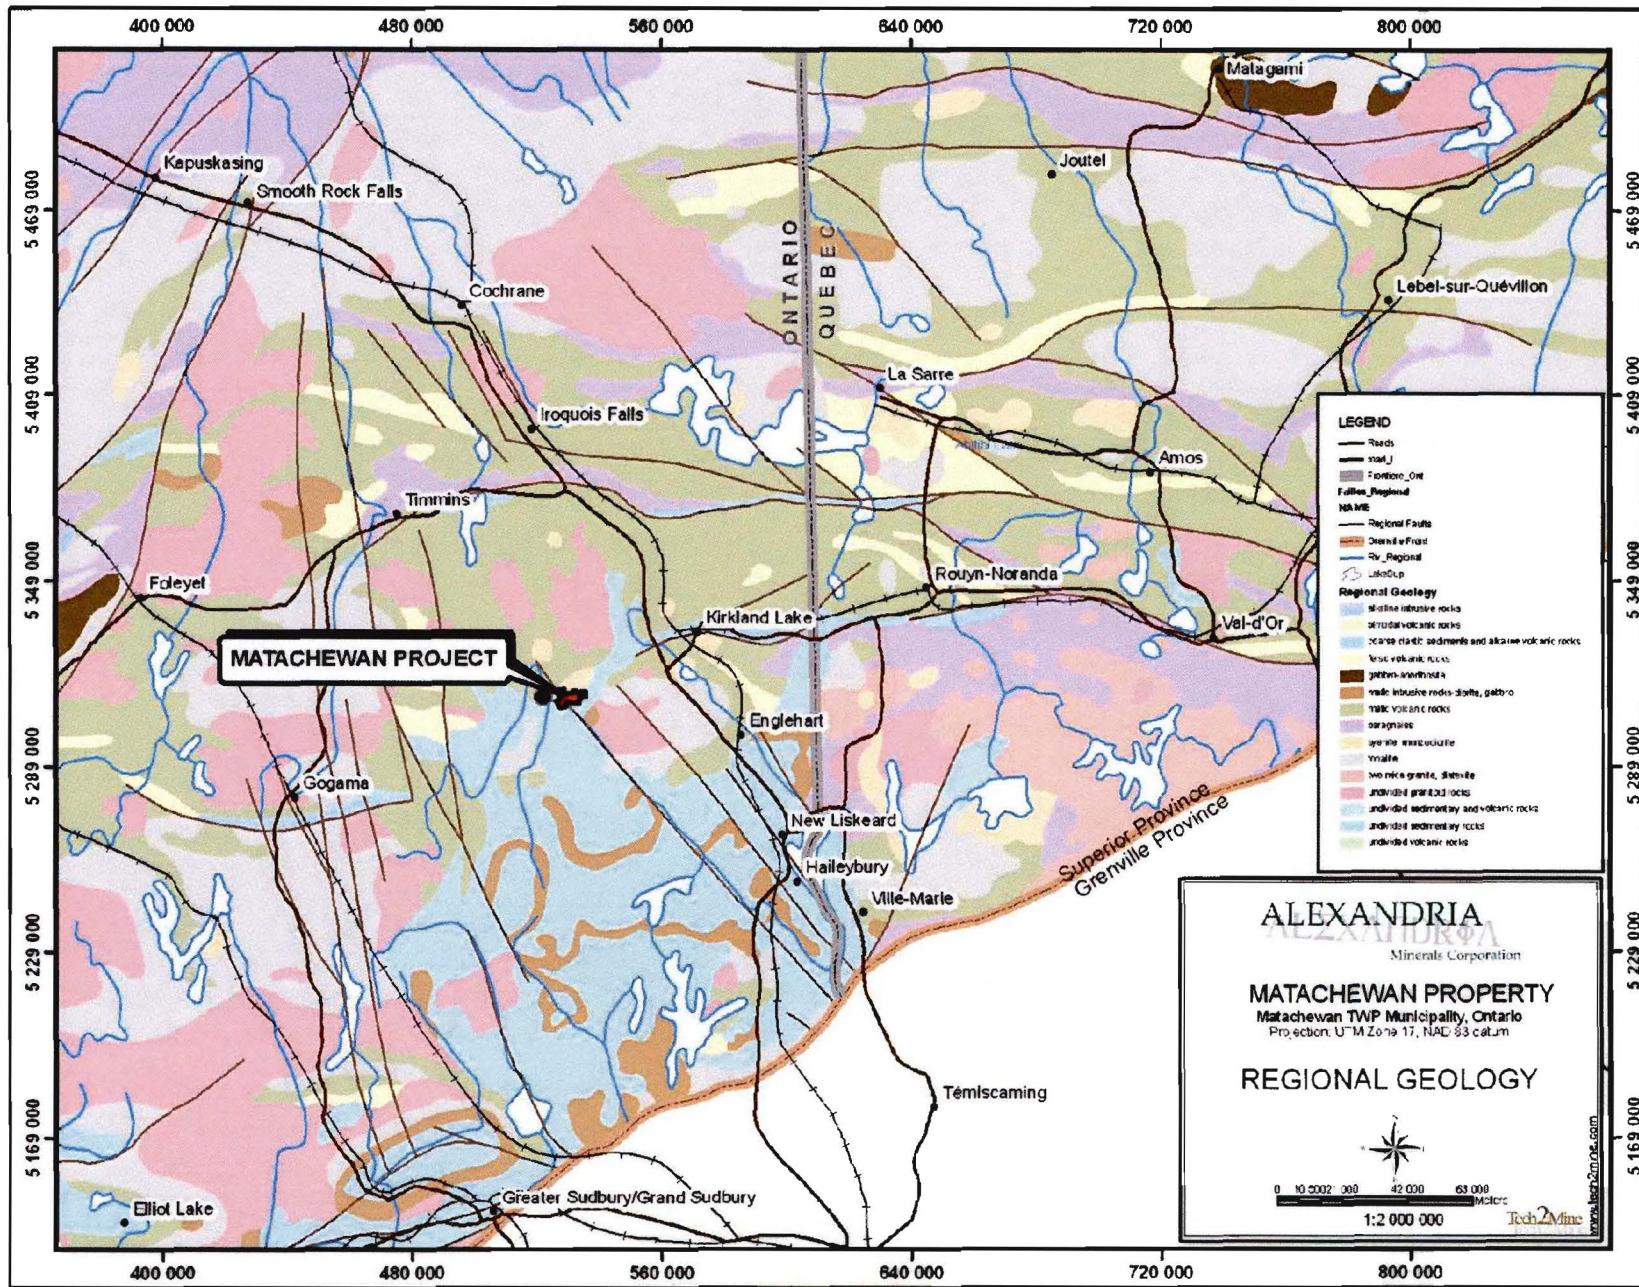

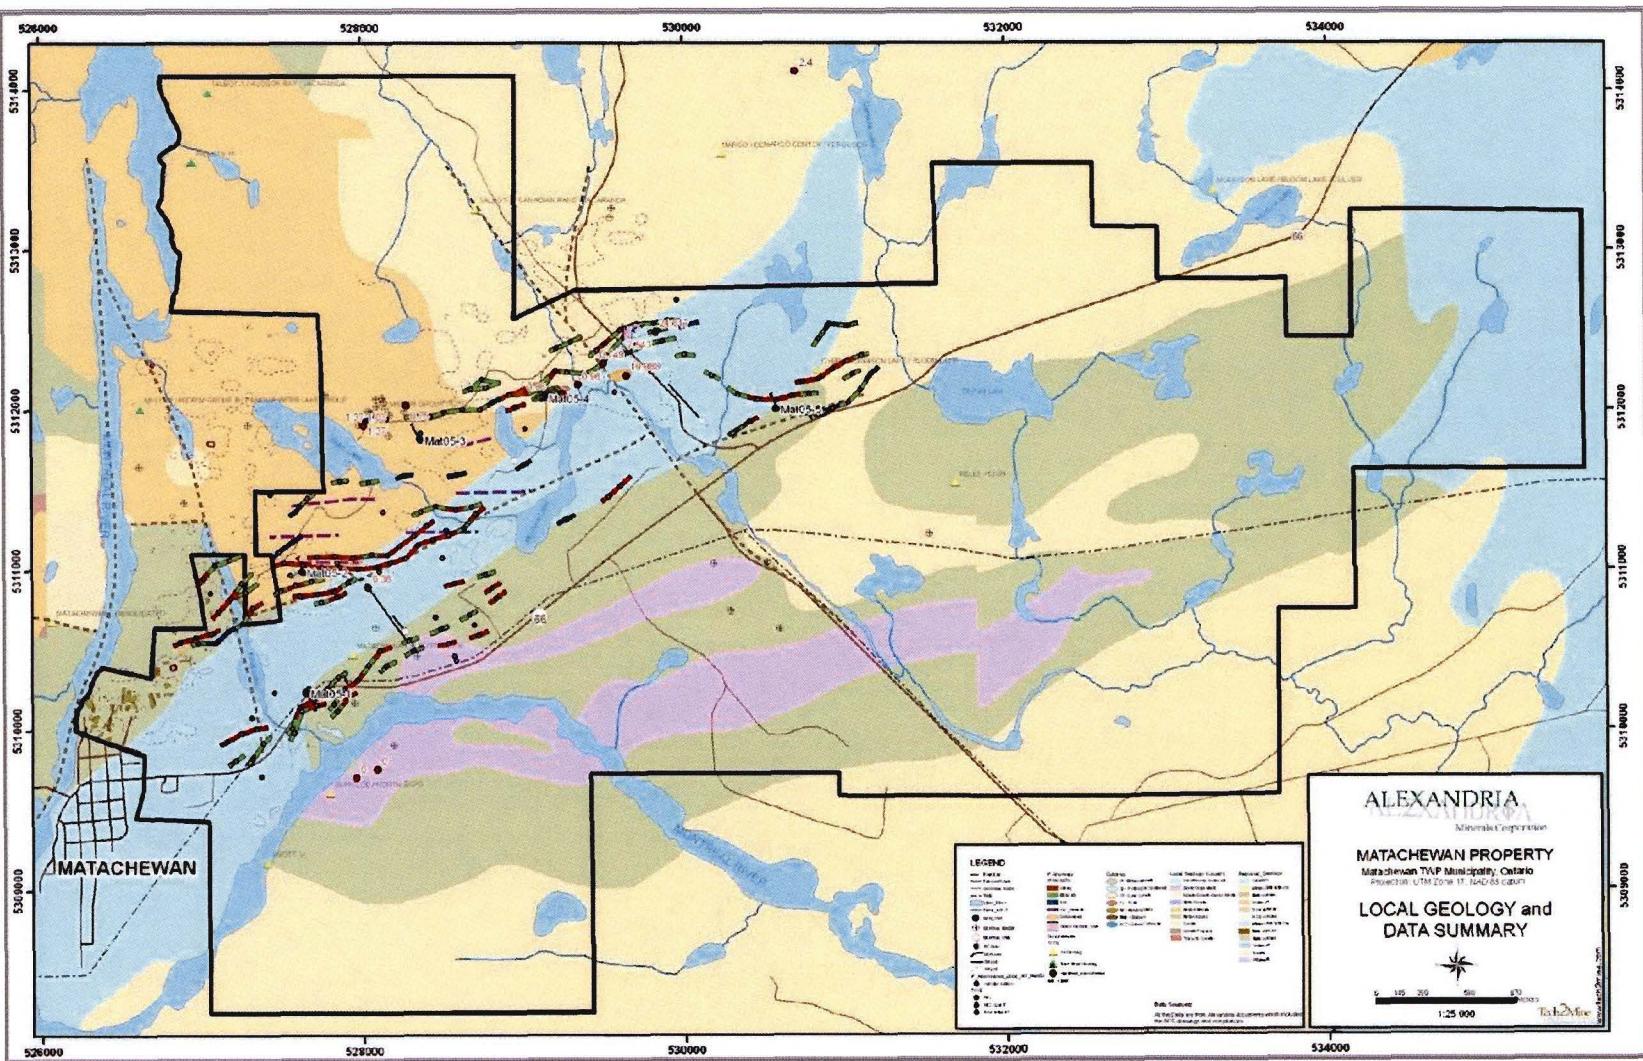

Figure 4. Local geology and Data Summary.

The supracrustal sequences have been intruded by plutonic rocks ranging in composition from ultramafic and mafic to intermediate and felsic. The age of these intrusions varies from early, syntectonic to late, post-tectonic. Early intrusions are commonly related to their host volcanic rocks (eg. co-magmatic), whereas late intrusions may be non-related to the surrounding rocks. Intrusive bodies may be small and parallel to, or cross-cutting, layering in the supracrustal rocks, or form large stocks and batholiths around which the layering trends.

Deformation in the Abitibi Belt is manifest by folds, shear zones, and faults and their related rock fabrics. At least two (2) major deformation episodes resulted in regional folds of distinct styles and orientation. Major shear zones ("breaks") form lens-like packages of rocks on the order of several tens of kilometers long, elongate roughly east-west. Supracrustal sequences are unified within each lens, and may or may not be related to rocks in adjacent packages.

The region is cut by two (2) or more distinct ages of Proterozoic diabase dykes trending northeast and north-northwest.

## **6.2 Local Geology and Property Geology**

The Matachewan area is underlain by a series of Archean mafic to intermediate volcanic rocks, and overlain by tightly folded sedimentary rocks of the Temiskaming Group (Table 3). These Archean units are cut by mafic and felsic intrusives which in turn are intruded by diabase dykes.

The units are all overlain by a series of flat lying Cobalt sediments. Late diabase dykes, Proterozoic in age, cut all of the units.

## **6.3 Structural Geology**

The area has undergone two (2) stages of deformation characterized by folds of distinct styles, and two (2) or more stages of shear zone development and fault activity. The first deformation is expressed by folding (F1) with axial planes oriented NE-SW. The schistosity developed with F1 has been deformed by the second stage of folding (F2), oriented E-W with subvertical crenulation cleavage.

The main shears in the zone are part of the Cadillac - Larder Lake Break (CLLB) shear system. Numerous shear zones and faults cross cut the area. Shear and sub-shear zones are oriented 55° to 65° and dipping steeply to the south (CLLB) and subparallel structures trend at 70° dipping steeply to the south. The CLLB shear zone extends through the property for at least 71.4 kilometers and the subparallel shears trend for at least 3.57 kilometers and may have widths of 10 to 60 meters.

## **6.4 Surficial Geology**

Glacial till covers much of the area. Previous drilling on the lake within the property has shown that overburden may be up to 65 meters in thickness. The eastern part of the property is also covered by overburden. The area was covered by the Labrador sector of the Laurentide Ice Sheet. Trends of surficial glacial features in the general area are SW to SSW.

## **6.5 Economic Geology**

Two (2) principal types of gold mineralization have been exploited in the Matachewan Camp. At the former Matachewan Consolidated Mine, three (3) kilometers west of the Property, early production was from a system of irregular orebodies consisting of a series of flat-dipping quartz stringers and adjacent altered, mineralized volcanics and/or tuffs. Gold occurred free within the quartz stringers and in pyrite in the stringers and adjacent wallrock. This type of ore averaged about 0.16 oz/ton gold.

The second type of ore produced there and at the neighbouring Young-Davidson Mine was from fractured, mineralized syenite porphyry with quartz occupying the fractures and most of the gold occurring with pyrite. The porphyry appears to be metasomatically altered where quartz, albite, and calcite have been introduced, and occurs within the sediments a short distance north of the sediments-volcanics contact. These types of orebodies contains larger tonnages but at lower gold grades.

Gold mineralization has been found at several different locations on the Property during the various episodes of surface exploration. Much of this past work is not recorded. Notable quantities of copper mineralization have often been recorded with gold. Notable concentrations of other minerals such as asbestos, barite, and molybdenite have also been found in the Matachewan area.

The area east of the Webb Lake and across to the northeast of Moyneur Lake carries the best indications of economic gold mineralization on the Property. This area covers a strike length of over two (2) kilometers. The host lithology is primarily variously sheared and altered metasediments intruded by numerous small syenitic bodies. Gold mineralization accompanies pyrite and chalcopyrite. Appreciable thicknesses of low-grade gold mineralization were intersected in Minorex drilling near Webb Lake. The RC drilling by Pamour in 1983, northeast of Moyneur Lake, may indicate higher grades of similar type gold mineralization.

The next most promising situation is the CLLB beneath the Cobalt Group in the central part of the Property. The sole hole to pierce this structure intersected encouraging gold mineralization on 2.5 kilometers of otherwise untested strike length. The sub-Cobalt geology is largely unknown, but is in part comprised of variolitic komatiitic basalt. The sub-Cobalt magnetic highs in the vicinity of Moyneur Lake may be indicative of syenitic intrusions flanking the CLLB.

The area from line 5000E eastward across the St. Paul Lake area and to the eastern Property boundary is prospective for syenite-mobilized gold mineralization in shears hosted by metavolcanics and metasediments. This East End Area features several subsidiary shears of the CLLB and, in combination with syenitic intrusives; these may form favourable loci for gold mineralization.

## **7.0 EXPLORATION**

No exploration work other than drilling was executed during this period.

## **8.0 DRILLING**

Drilling on the Matachewan property was performed between the months of January and March 2008. Three (3) holes were drilled on the Matachewan Property (Figure 2 and 4) following up on IP Chargeability anomalies and Low mag anomalies.

Table 2 below lists the three drill holes with their respective locations, length, orientations and objectives.

Drilling was executed by Forage Orbit-Garant from Val-d'Or and was drilled with NQ core size for a total of 1,621.0 meters. Drill logs and the assay certificates are in the Appendix I & II respectively and the drilling holes sections are in Appendix III.

Hole	Local Line	Local Station	UTM E	UTM N	Claim	Length (m)	Azimuth (°)	Dip (°)	Reason
MAT-08-06A	1700	100	527768.5	5310696.7	1200215	648.0	335	-50	South of MAT-05-2 drilling shear, contacts and IP anomalies.

Total Length:								1,621.0	meters

**Table 2.** 2008 Drilling Holes location and specifications, on Alexandria Matachewan Property.

Drill hole **MAT-08-06A** intersected greywackes, conglomerates, basalts, gabbros, ultramafics, monzodiorites, aphanitic syenites (or trachytes) and black chlorite - graphite units and with extensive shearing and mylonitization. The basalts and gabbros are frequently cut by carbonate - chlorite veinlets, and the conglomerates, monzodiorites and aphanitic syenites are often altered with hematite. The units are mineralized with traces to 3% disseminated pyrite and stringers of pyrite. Units that are more extensively altered in dark chlorite and with the presence of graphite have up to 5% pyrite present. Assay results indicate anomalous gold values up to 0.297 g/t Au over 1.5 m at a depth of 396.0 m within monzodiorites. A number of anomalous gold values occur between the depth of 348.0 m to 406.5 m grading between 0.115 g/t Au to 0.297 g/t Au (See Table 3).

Hole ID	From (m)	To (m)	Au g/t Avg	Width(m)
MAT-08-06A	348.00	350.5	0.15	2.5
MAT-08-06A	393.0	394.5	0.13	1.5
MAT-08-06A	396.0	397.5	0.297	1.5
MAT-08-06A	402.0	403.5	0.13	1.5
MAT-08-06A	405.0	406.5	0.115	1.5

**Table 3.** Bests results of Hole MAT-08-06A.

The second drill hole, **MAT-08-08**, intersected basalts, ultramafics, gabbros, monzodiorites, monzonite and black chlorite - graphite schists of which some of the units are partly sheared and mylonitized. A length of 34.1 meters of highly sheared units occurs at 375.2 m to 409.3 m, with high hematite, chlorite and carbonate; they may represent in part deformed – altered mafic volcanics, volcaniclastics, lapilli tuffs, conglomerates and/or blocks or tectonized – hydraulic breccias. Chlorite, carbonate, hematite and epidote are common. The pyrite content varies between 0.5% to 2%, especially in the deformed sections. The anomalous intersections presented below occur in sheared and mylonitized monzonites, ultramafics, and basalts respectively, containing 1% to 2% pyrite.

Hole ID	From (m)	To (m)	Au g/t Avg	Width(m)
MAT-08-08	92.0	93.5	0.154	1.5
MAT-08-08	101.0	102.5	0.13	1.5
MAT-08-08	260.0	261.5	0.155	1.5

**Table 4.** Bests results of Hole MAT-08-08.

Drill hole **MAT-08-09** intersected basalts, intermediate to mafic lapilli tuffs, gabbros, monzodiorites, monzonites and carbonate - chlorite schists. These lithological units are locally sheared and mylonitised, which tend to be sections that have anomalous gold grades (See Table 5). The deformed sections and intrusive contacts contain chlorite, carbonate, hematite, epidote and occasionally sericite. The pyrite content varies from 0.5% to 3% pyrite. The highest gold assays are presented on Table 5, with the section beginning at 368.0 m hosting anomalous grades at 0.12 g/t Au over 10.5 m tectonized and brecciated intermediate to mafic tuffs.

Hole ID	From (m)	To (m)	Au g/t Avg	Width(m)
MAT-08-09	23.0	24.5	0.11	1.5
MAT-08-09	90.5	92.0	0.103	1.5
MAT-08-09	324.5	326.0	0.12	1.5
MAT-08-09	335.0	336.5	0.21	1.5
MAT-08-09	368.0	378.5	0.12	10.5

**Table 5.** Bests results of Hole MAT-08-09.

## 9.0 SAMPLING METHOD AND APPROACH

Sampling method for this exploration program is considered to be appropriate and accurate.

## 10.0 SAMPLE PREPARATION, ANALYSES AND SECURITY

For the 2008 drilling program, the core sampling protocol was established by Eric Owens of Alexandria Minerals Corporation and verified by Mr. Eddy Canova. Once the drilling core was extracted, the sampling method was as follows:

- 1) Core was washed with water and a brush;
- 2) Before logging commenced, pictures of the core boxes were taken in its entirety;
- 3) Once the geology and location of the samples were described, the geologist oriented the core, marked the start and end of the sample directly onto the core with a coloured wax crayon while the core is still intact in the core box, allowing consistent sampling.
- 4) The core is generally sampled over regular intervals varying between 30 cm minimum and 150 cm maximum;
- 5) Samples are measured to the nearest tenth of a centimeter, but sample intervals have to coincide with major lithological boundaries;

- 6) A sample tag, especially made of waterproof paper and legible ink, is placed at the start of the sample interval. Each sample number is unique and entered in the database, a distinct series is used (11001 to 11362);
- 7) Standard tags are inserted by the geologist into core boxes;
- 8) Samples were split with a hydraulic splitter in a core shack. Samples were split in half, lengthwise, using a diamond core saw (or split) in order to provide witness samples;
- 9) Half the sample, top half, (assay sample) is placed separately in a plastic bag tied with a plastic ribbon. The other half returns to the box according to its original position in the core box and retained for future reference;
- 10) In the case of "grinded core", samples are taken by hand with a scoop and a representative part is kept in the core box;
- 11) The other identical sample tag is stapled into the core box with a dymo tag with the sample number at the beginning of the marked sample interval;
- 12) Each canvas sample transport bag has 25 samples. The request form specifies the name of the laboratory, the person making the request, the date, the sample series, assaying method, the units for the results to be reported (g/t Au), the analytical method and any other special instructions;
- 13) One CRM sample was introduced within each batch of 24 core samples. The CRM sample introduced from Rocklabs Jar No. 82499 with the values of gold equal to 8.367 ppm Au and silver equal to 17.64 ppm Ag;
- 14) The bags are prepared for shipment to the laboratory with a work order sheet filled and included in the first bag;
- 15) Each bag of 25 samples are tied with a "tape" to seal the bags, these are ready to be shipped to the laboratory.

## **11.0 DATA VERIFICATION**

The author did not take any samples to verify the assay data.

## **12.0 INTERPRETATION AND CONCLUSION**

The Matachewan Property has a favorable geological environment in terms of gold potential. Classical Archean environments include structural deformation in the form of fault and shear zones, as manifest by the Larder Lake Cadillac Break and related faults, the presence of pre- to syntectonic intrusive rocks, and metamorphic grade. Furthermore, regional-specific geological characteristics, such as the presence of quartz-poor intrusive rocks, such as syenite, and the Archean volcanic-sedimentary boundary, both of which are related to gold deposits in the Matachewan to Kirkland Lake region, indicate a positive environment.

Exploration data, and geologic and geophysical evidence on the Matachewan property support the conclusion that the environment is consistent with attempting to discover a gold deposit: the location along strike with the 2.8 million ounce Young Davidson gold deposit; anomalous to high grade gold values in drill core and at the surface; strong IP anomalies; widespread alteration similar to that at Young Davidson.

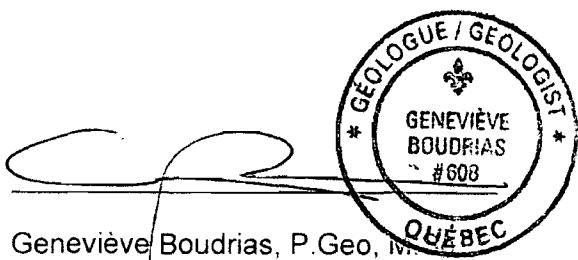

## 13.0 RECOMMENDATIONS

It is recommended that a program of 2000 m of drilling be setup to further follow up some of the anomalous gold mineralization values especially obtained in the previous drill holes MAT05-1,2,3,4, MAT08-6, and 9 along sheared sediments, volcanics and syenites and at the sediment – syenite sheared contacts. Further to the east, drill holes MAT05-5 and MAT-08-08 penetrated highly sheared – mylonitized volcanics in contact with syenites and this may be a favorable gold mineralizing environment.

## 2009 PROJECT BUDGET

Program Description	Depth - Quantity	Unit Cost /m	Estimated Cost
Diamond Drilling	2,000	63.25\$*	126,500 \$
Assaying	1,000	30\$*	30,000 \$
Geologist (1)	1.5	90,000	11,250 \$
Technician (1)	1.5	70,000	8,750 \$

## 14.0 DATE AND SIGNATURE PAGE

### CERTIFICATE OF QUALIFICATION

I, **Geneviève Boudrias, P.Geo. M.Sc.**, do hereby certify that:

1. I am a consultant geologist with office at 113, rue des Sapins, Val-d'Or, J9P 4R4, Canada.
2. I graduated with a Master degree in Geology from the University of Quebec at Montréal in 2002.
3. I am a member of the "Ordre des géologues du Québec (OGQ)", member # 608, of the Quebec Mining Exploration Association (AEMQ).
4. I have worked as a geologist for a total of 7 years.
5. I am responsible for the preparation of the report titled "Report on the 2008 drilling campaign on the Matachewan Property, Cairo Township, Ontario." and dated July 2<sup>nd</sup>, 2009. I have not visited the subject property.
6. I have not had prior involvement with property that is the subject of the Report.
7. I am independent of the issuer (Alexandria Minerals Corp.).

Dated this 20<sup>th</sup> day of October, 2009.

Geneviève Boudrias, P.Geo. M.Sc.

## CERTIFICATE OF QUALIFICATION

I, Eric Owens, P.Geo., PhD., do hereby certify that:

1. I am a geologist currently employed as President of Alexandria Minerals Corporation with an office at 100 Adelaide St. West, Ste 405, Toronto, ON, M5H 1S3, Canada.
2. I graduated with a PhD degree in Geology from the University Western Ontario in 1991.
3. I am a member of the "Association of Professional Geoscientists of Ontario (APGO)", member # 175, member of the Society of Economic Geologists, and of the Prospectors and Developers Association of Canada.
4. I have worked as a geologist for 35 years.
5. I am responsible for the factual and correct presentation of the report titled "Report on the 2008-2009 drilling campaign and mapping programme on the Matachewan Property – Carmax Option, Cairo Township, Ontario" and dated September 10<sup>th</sup>, 2009. I have visited the subject property.
6. I am not independent of the issuer (Alexandria Minerals Corp.).

Dated this 20<sup>th</sup> day of October, 2009.

Eric O. Owens, P.Geo, PhD.

MAT-08-6	549.90	563.90	I2J		2.10 Diorite	grey - green	md				HB	0-2		72	553.9	67	QZ-Cl-CB	3.0	1.5	1.5	1.5															1	1	Diorite; grey-green; partly massive; partly foliated; medium grains; moderate alterations of carbonate and chlorite. The unit contains 3.0% of quartz-chlorite-carbonate veinlets and 0.1 % of pyrite. Contains relict of xenoliths composed mainly of fragments of chlorite.
MAT-08-6	563.90	565.80	M25		14.25 Mylonite	green	fi			HB				87	565.8	70	CB-CL-QZ	3.0	1.5	1.5	1.5														0.1	0.1	Mylonite; green; partly foliated; partly brecciated; partly fractured; fine grained; weak alterations of carbonate, hematite and chlorite. This section the so-called agglomerate. The section include 3% of quartz.	
MAT-08-6	565.80	568.00	I2J		2.10 Diorite	grey	co					2		70	570.1	72	QZ-Cl-CB	2.0	1.0	1	1														0.1	0.1	Diorite; grey; partly massive; partly foliated; coarse grains of plagioclase; weak alterations of carbonate and chlorite. The unit contains 2.0% of quartz-chlorite-carbonate veinlets and 0.1% of pyrite.	
MAT-08-6	568.00	570.10	M8 (I3A)		14.08 sheared gabbro	dark grey-green	fi-md					2		72	572.8	65	QZ-Cl-CB	3.0	1	1															0.1	0.1	Sheared gabbro; dark grey-green; foliated; fine to medium grains; weak alterations of hematite and chlorite. The unit contains 3% of quartz-carbonate-chlorite late veinlets and trace of pyrite. Strong.	
MAT-08-6	570.10	572.10	M25		14.25 Mylonite	grey-green	fi					2		65	576.6	65	CB-CL-QZ	2.0	1	1															0.4	0.4	Mylonite; grey-green; fine grains; foliated; weak alterations of hematite and chlorite. The unit contains 2% of carbonate-chlorite-quartz veinlets and 0.4% of pyrite. Strong magnetism provoked by magnetite.	
MAT-08-6	572.60	577.50	I2H		2.08 Monzodiorite	grey-red	fi-md					2		65			QZ-Cl-CB-HE(CP)	2.0	1	1															0.4	0.4	Monzodiorite; grey; foliated; fine to medium grains; moderate alteration of hematite; weak alteration of quartz-chlorite. The unit contains 2.0% of quartz-chlorite-carbonate-hematite (CP) veinlets and 0.4 % of pyrite. Millimetric veinlet of chalcopyrite-carbonate-chlorite parallel to the major foliation. Strong magnetite provoked by magnetite.	
MAT-08-6	577.50	578.80	M25-M8 (I2H)		14.25 Mylonite-schist and some monzodiorites	grey - green	fi(md)					0-2						QZ-Cl-CB	2.0	1.0	1	1													0.4	0.4	Mylonite and some monzodiorites; grey-green; fine to medium grains; foliated; medium alteration of hematite; weak alterations of carbonate-chlorite-biotite-silification. The unit contains 2.0% of quartz-chlorite-carbonate veinlets and 0.4 % of pyrite. Strong magnetism provoked by magnetite.	
MAT-08-6	578.80	583.70	I2H		2.08 Monzodiorite	grey	fi-md				CL-CB-QZ				584.4	73	QZ-Cl-CB	2.0		1	1														0.4	0.4	Monzodiorite; grey; partly massive; fine to medium grains. Strong alteration of hematite; moderate alteration of silification and weak alteration of chlorite. The unit contains 2.0% of quartz-chlorite-carbonate veinlets and 0.4 % of pyrite. Irregular magnetism.	
MAT-08-6	583.70	584.85	M25-(I2H)		14.25 Mylonite and some monzodiorites	reddish green	fi(md)	FD	CL-CB-QZ		0-2	73			QZ-Cl-CB	2.0	2.0	2	2														0.4	0.4	Chlorite-carbonate - hematite schist -mylonite; reddish green; fine to medium grains; including some short sections (maximum 20 cm) of massive reddish green monzodiorite. The sections shows medium alteration of hematite-carbonate-chlorite; weak silification and possible biotitisation; 2% of quartz-chlorite-carbonate late veinlets and 0.4 % of pyrite.			
MAT-08-6	584.85	592.50	I2D or V2D		2.03 Syenite or trachyte	red-grey to red	fi(md)					0-2	AP				QZ-Cl-CB	3.0	1.0																2	2	Syenite or trachyte; grey-red to red; massive; fine to medium grains; strong alteration of hematite; weak alterations of quartz and carbonate. The unit contains 3.0% of quartz-chlorite-carbonate veinlets and 2.0% of pyrite. Mainly massive; strong hematitisation; 3 % of late quartz-carbonate-veins and 2% of pyrite. Irregular magnetism provoked by magnetite and pyrrhotite.

MAT-08-9	73.2	74.5	I2H	14.24 Cataclastic - brecciated (monzonite or dacite or trachyte)	Pinkish to greenish white	fi to co			4% FRAg; FR (FO)		70	2		CbQz	1	2	1											0.2	Cataclastic - brecciated dacite or trachyte; pinkish to greenish white; partly fractured; partly foliated; fine to coarse grains; moderate alteration of carbonate; weak alterations of hematite and chlorite. The unit contains 1% of quartz-carbonate veinlets and 0.2% of pyrite. The unit contains 4% of clasts-diameter > 1.0 cm.					
MAT-08-9	74.5	79.5	M24 (I2F or V1D or V2D)	14.24 Cataclastic - brecciated (monzonite or dacite or trachyte)	Pinkish to greenish white	fi to co			FR; clasts; (FO)		68			CbQz	1	2	2											0.5	Mylonite-cataclastic dacite or trachyte; pinkish to greenish grey; partly fractured; partly foliated; fine to medium grains; moderate alterations of carbonate and chlorite; weak alteration of hematite. The unit contains 1% of carbonate-quartz late veinlets and 0.5% of pyrite. The unit exhibits 15 % of clasts-diameter > 1.0 cm. Fragmentations come from mainly transposed folds found within older carbonate-quartz (hematite) and anastomosed foliations but other sources may be possible.					
MAT-08-9	79.5	84.8	M25- M24 (I2F or V1D or V2D)	14.25 Mylonite - cataclastic - breccias (monzonite or dacite or trachyte)	Pinkish to greenish grey	fi (md)			MA; clasts	60				CbQz	1	2	1											0.3	Brecciated monzodiorite - trachyte or possible lapilli tuff or conglomerate wacke (debris flow; avalanche ?); pinkish to greenish grey. The unit shows from 1 to 25 % of polygenic clasts > 1.0cm within massive; fine to coarse grains groundmass. Cleavage or foliation observed from this unit is relatively weak; the unit contains some stretched fragments but rounded and angular clasts up to 7cm are mainly observed. The unit shows locally some granulometric changes (varying 2mm to 3.0cm) suggesting primary gravitational deposits (beds) or secondary ascending fluidisation layerings which may be different from the habitual cleavage found within the drilled hole. Fine- grained material such as ash tuff or shale is missing. This brecciated section shows moderate alteration of carbonate; weak alterations of chlorite-hematite. The unit contains 1% of carbonate-quartz-epidote late veinlets and 0.3% of pyrite, locally disseminate as coarse cubic grains.					
MAT-08-9	84.8	102.5	M25 (V1D or V2D) - T4? or TL?	14.25 Mylonite (dacite or trachyte) - tectonic breccia or possible lapilli tuff	Pinkish Greenish grey	Fit to co																						0.3	Mylonite-cataclastic dacite or trachyte; pinkish to greenish grey; partly fractured; partly foliated; fine to medium grains; moderate alterations of carbonate and chlorite; weak alteration of hematite. The unit contains 1% of carbonate-quartz late veinlets and 0.3% of pyrite, locally disseminate as coarse cubic grains.

The unit contains 2% of carbonate-chlorite (quartz-pyrite) veinlets and 0.5% of very fine pyrite. Same unit than 419.5 to 422.0 but the porphytic feldspaths here show zonal phenocrysts which contains slight alteration of chlorite-hematite.			
MAT-08-9	434.3	441.9	I2J	2.1	Diorite	reddish green	coarse	FD	HB (BO)	(PO)	MA		45	CB-CL	2		1	1												0.5	0.5 Cleavage at 434.33. Cataclasite-mylonite - breccias observed within diorite and chlorite-carbonate schist. The entire section shows variable tints of green; is partly brecciated; partly foliated; locally massive. The massive diorite exhibits fine to coarse grains; strong alteration of chlorite; moderate alteration of carbonate; weak alterations of hematite-sericite. The unit contains 15% of carbonate-chlorite (local quartz-pyrite) veinlets and 0.5% of pyrite. The matrix of the brecciated part is filled by green to dark green chlorite and some veinlets and veins of carbonate. The chlorite observed within some chlorite-carbonate schist may be sheared matrix. Locally magnetic (magnetite, pyrothite ?).

**CERTIFICATE VO08010972**

Project: MATACHEWAN

P.O. No.: MAT-08-6A (B)

This report is for 5 Drill Core samples submitted to our lab in Val d'Or, QC, Canada on  
30-JAN-2008.

The following have access to data associated with this certificate:

EDDY CANOVA

ERIC OWENS

**SAMPLE PREPARATION**

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter

## CERTIFICATE VO08032859

Project: MATACHEWAN  
P.O. No.: MAT-08-08 (B)

This report is for 17 Drill Core samples submitted to our lab in Val d'Or, QC, Canada on 19-MAR-2008.

The following have access to data associated with this certificate:

EDDY CANOVA

ERIC OWENS

## SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

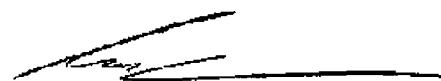

## ANALYTICAL PROCEDURES

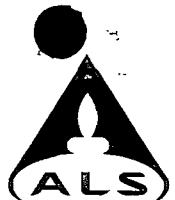

ALS CODE	DESCRIPTION	INSTRUMENT
Cu-AA45	Trace Cu-Aqua Regia Digestion	AAS
Zn-AA45	Trace Zn - aqua regia/AAS	AAS
Au-AA23	Au 30g FA-AA finish	AAS
Ag-AA45	Trace Ag - aqua regia/AAS	AAS

To: ALEXANDRIA MINERALS CORP.  
ATTN: EDDY CANOVA  
1273, 5E RUE  
VAL-D OR QC J9P 4A1

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.
