4-Corners Area, Kamiskotia Project
 Diamond Drilling of Jan - Feb 2010
 Hermann Daxl, M.Sc. 31 Dec 2010

Introduction

The present work concludes the orientation soil sampling I started in October 2006 and partially reported with T-5751 (400-series samples) and T-5809 (500-series), of the 4-corners area of Jamieson, Godfrey, Turnbull, Robb Townships. These clearly showed zinc-cadmium anomalies where such occurrences are known. Gold was too close to detection limits, although it sometimes agreed with minor known occurrences. The attached repeat analyses show several discrepancies.

Presently, on 15 - 23 Oct 2009, I took infill soil samples (601-675), and several rock samples (3012 - 3024), on claims 3010919, 3011003, 3012747, 3012748, 3012749, 4246485. On 14 - 17 Nov 2010 I collected decay samples (681-699) which are the recommended further exploration method for the region.

For background, on 19 July 2010 I took soil samples (701-725) of a 500 x 300m area 1.6 km West of Kamiskotia Lake within claim 4246485, where no mineral occurrence is known.

As previously, I did all work including sieving the samples myself, adhering to the same procedures and <150 micron sieve, except that I used the coarser <300 micron sieve for the 400 series, and by necessity for the decay samples.

Again all samples were analyzed by Activation Laboratories Ltd., the soils with aqua regia - ICP/MS (UT-1), which finally was found unreliable for gold, so that selected soils of 400 and 500 series, and all of 701-725 were redone with enhanced neutron activation 1D enh.

The decay samples 681-699 were analyzed by aqua regia - ICP/OES (1E3), as well as neutron activation 1 D enh which however next time should be done by Vegetation Code 2B in 1g vials, as with a 0.1 ppb Au detection limit this is more precise, and is best suitable for gold in decays. 1E3 may work for a few base metals but UT-1 or UT-2 is necessary for other elements such as Ag-Cd-Co-Pb-P-S.

Location

The areas lie in the regional Kamiskotia Gabbroic Complex, reportedly a tholeiitic intrusive overlain by the Kamiskotia Volcanic Complex of basalt and rhyolite. According to drill core I logged of the 4-Corners (T-5529, T-5615, T-5631, and 2.47250), the gabbro is quite variable and fine-grained, or more locally older epidotized medium-grained, but always with 2 to 5% laminated sometimes magnetic ilmenite-hematite which makes strong IP chargeability anomalies. The felsic units seem to be metamorphosed sedimentary rocks engulfed by the gabbro, sometimes with quartz-veins and associated gold-bearing pyrite cubes

in contact areas. More important are the quartz veins with much gold-bearing sphalerite, which make conspicuous Zn-Cd soil and decay anomalies, the latter also showing the gold more clearly.

The topography sampled ranges from hummocky outcrops, to variable sand and clay overburden with conifers and deciduous trees, to deep black muck in alder swamps. Such deep muck samples were kept separate now and values marked as humus (H) to show that cadmium values seem to be naturally higher in them as seen also in other areas, or they possibly are spread more widely by swamp water. This sheds doubt on the cadmium anomalies of the 500 series because I took the few samples at the black-green interface to clay.

Access to 4-Corners 20 km West of Timmins is simple from Highway 576 at 3km east of Kamiskotia Lake, or to claim 4246485 around Kamiskotia Lake to its southwest side and then from NAD83 452080E - 5378760N 1.6 km westward on a worsening wet dirt trail.

The recent location and element maps, sample descriptions and tables, and analyses, are part of this report.

Present Results

Previous Soil Sampling now outdated for Gold

The 601-675 series soil sampling of the attached element maps and sample list followed the same procedures and analyses as 400 and 500-series, sieved to <150 micron. The anomalies are described with the decay samples. According to test samples the gold values should have been 3 times as high. I marked the few samples of black deep swamp humus with H as a separate population. The elevated Ag and especially Cd may be normal in such deep muck, where background seems also somewhat higher for Cu-U, but lower for Pb.

Although the previous soil sampling of the enriched horizon worked well for zinc and especially its associated cadmium, values for gold are too close to detection limits for such material. Since the decay sampling described below shows zinc and cadmium also very well or even better, but also works especially well for gold for which in addition it allows especially low detection limits, it is now the preferred and also much simpler method for this area.

However, I could not prove whether either method works for copper, or in deep swamps, or for the many other elements resulting from the recommended analyses. The iron oxide of an enriched soil horizon should always scavenge elements, but it is usually only found in dry sandy locations, which does not seem to matter for decay samples as the present study included such locations as well

as shallow wooded swamps and others. An open mind for further research is necessary.

Trust only Decay Samples for Gold

Of the 24 re-analyses (A11-0165) of selected 400 and 500 series soil samples to verify gold by neutron activation enhanced (1D enh) to a 2ppb Au lower limit in packed 1-g vials, gold was confirmed only in sample 537 with 11 ppb Au, which is sample 437 of silty sand along strike of ZnV1. Gold results of 0.5 g aliquots by aqua regia - ICP/MS (UT-1-0.5g) are therefore unreliable as also concluded in other areas, because gold tends to collect in the plastic tube and releases at random, even if test samples are placed only at the end of a batch. However, several such gold anomalies actually fit occurrences, so that one cannot trust 1 D enh either, probably because values in soils are too close to the detection limit of <2ppb Au.

Decay samples are the top 0 - 6 cm of humus after scraping aside loose debris, moss and green vegetation. The exposed felt of tiny rootlets, dead leaves, encrustations and mould, without any black soil or sediments, is easy to sample, quite standard almost anywhere, and has given the highest values of gold over gold-bearing veins at the Dayton showing, the McEnaney Resource, the Highway Gold showing just north of highway 576 here (T-5631, T-5751), and also shows gold occurrences here. In addition to higher gold content, decay samples allow the lower detection limit of only 0.1 ppb Au by neutron activation - vegetation code 2B pressed into 1-g vials, because they are basically vegetation.

Decay samples are not described individually because they hardly vary throughout, and all were taken in wooded areas, but annotations on analyses were necessary. Maps of the present decay samples 681 - 699 and their elements are attached. Strong zinc-cadmium anomalies occur where expected, and their associated gold also shows despite the 1D enh analyses which in future should be Code 2 B for its lower detection limit. Please refer to the enclosed plan with the drill holes CP-10-12 to 15 to correlate anomalies with occurrences.

Decay samples also show strong zinc and cadmium anomalies here by aqua regia - ICP/OES of 0.5 g aliquots (1E3), but aqua regia - ICP/MS Ultratrace 2 (UT-2 - 0.5g) is recommended because of the additional elements including P and S, and the necessary lower detection limits for Ag-Cd-Co-Pb, and others.

Decay samples 687 -688 indicate the gold showing up-slope, whereas the previous soil anomalies by UT-1 could not be repeated by 1 D enh. Sparse particles in silt could be blamed, but they would hardly occur in decay, as a 10 x 10 x 1 micron gold flake in a 1 g aliquot would approximate 1 ppb Au.

The anomalous gold in decay 682 - 683 of 6 and 23 ppb Au by 1 D enh, with Cd but no Zn by 1E3; and Cd-Fe-Pb but no Au-Zn in enriched sand 614 - 618 by UT-1, may be due to aplite and deuteritic dikes with gold-bearing pyrite intersected at 112m 15CA in CP-10-12. Two faults and a change in magnetism of the gabbro also occur below the area. A 2-m thick massive magnetite dike at 135m downhole, and traces of gold below to 217m were also intersected.

The drilling map also shows the intersections of the set of quartz veins with gold-bearing sphalerite in CP-10-15 under weak Ag-Cd-Zn-Pb-Fe anomalies in clay or sand of the 600-series soil samples.

The background in decay samples is somewhat higher for cadmium, lead, and maybe sulfur, than in soil samples, but the few anomalous values for zinc and cadmium are similar in soils. Copper may not work, but gold so far <143 ppb Au makes much stronger true anomalies in decay than in soils, which therefore can be differentiated from vague statistical anomalies or drifting analyses.

Decay Sampling Procedure

Scrape aside loose debris, moss, and green vegetation, at three spots to expose the maze of rootlets, dead vegetation with encrustations and mould, where there still is no black humus or other soil. From 0 - 6 cm grab a fistful at each of the three different spots. Dried below 60C, and rolled with a bottle to liberate encrustations, this will usually yield the necessary 2g sieved onto paper with a <300 micron plastic coffee filter available in stores.

8-g briquettes of a macerated whole dry samples gave lower but still recognizable values, however, the goal is to sample the encrustations not the vegetation debris, following the hypothesis that the elements are left like efflorescence on brick after the water evaporates or is taken up by the tiny rootlets.

Mobile metal ions may also favor this top 0 - 6cm, especially since <143 ppb Au was found there but no gold was detected in the other soil horizons, not even in the enriched sand, nor the black swampy muck, nor in the horizon suggested by the MMI-method, at the Dayton showing. This rules out that the gold is scavenged by the iron oxides of the enriched horizon, although one would expect that, because it could not be that all gold gets removed by tree roots below.

In this second hypothesis the trees take up the gold deeper down and it is contained in the decayed leaves and needles. The wide-spread anomalies would speak for that, however, there were hardly any leaves or needles under the frequent moss. In this case the method would work only in forests. It has not been tested in open swamps yet.

This decay sampling method has shown gold values up to 143 ppb spread over 100m across the 5-m wide Dayton showing. It has already been taught at Queens University in 1987 as the only method to find real gold anomalies. It is now also proven to work for Zn-Cd, but a small copper deposit under a 10m cedar swamp did not make an anomaly.

Samples should be taken at selected spots, with GPS location, rather than on a grid. A worthwhile deposit should show on approximate 50m nodes. Detailed sampling and evaluation is then necessary for each anomalous result. Since the medium will always be the same, notes need to be taken only of special situations or reasons for selecting the spot. Therefore I have not described the samples individually, but merely plotted the values, and annotated the analyses.

Two types of analyses will be necessary, neutron activation - vegetation code 2B on 1-g packed vials, with a detection limit of 0.1 ppb Au, for gold; and aqua regia - ICP + ICP/MS Ultratrace 2 - code UT-2-0.5g on 0.5g aliquots, even to cover the basic anomalies. The list price was \$21.50 and \$26.50 respectively for these two analyses, if sieved samples are submitted.

Comparison with Kam-West

Soil samples 701 - 725 from inside claim P4246485 sieved to <125 micron were analyzed by Ultratrace 1, which is aqua regia - ICP/MS - UT-1-0.5g, and 1D enh neutron activation on 1 g vials to verify >2 ppb Au. Sample 716 first was 5 ppb Au, was rerun as <0.5 ppb Au by UT-1 and <2ppb Au by 1D enh, and its gold is therefore considered due to the test pulp run before it.

Sample 708 of 783 ppb Ag is from varved clay at 70-100cm depth. Sample 709 of 49 ppb Ag at 10m south is from enriched varved clay at 20-30cm depth. The surface is 10cm sand without humus. A sparse particle of silver could be assumed, although sample 723 of 143 ppb Ag nearby is also in deep clay.

Sample 718 with anomalous 6 ppb U (uranium), 167 ppm Ce (cerium), 19 ppm Pr (praseodymium), 71 ppm Nd (neodymium), 178 ppb Ag, is from 80cm depth of thick packed black clay, abruptly overlying beige wet clay, in a wet gully with muscovite? sloping eastward. Such values are similar in tonalite of CP-10-14. Such uranium is quite common in black muck, but here it is packed.

The area is of similar geology as the 4-corners area, which was confirmed by the similar soil background of the many elements. The similar lead values which at times seemed anomalous when 10 - 16 ppm Pb at 4-corners, are therefore considered normal , which explains why no lead was encountered in drilling there.

New gold-bearing outcrop sampled

My follow-up on the cluster of gold anomalies of the 500-series soils sampled in 2008, revealed a 3m wide gold-bearing shear zone cleaved 285/70 at 455931E - 5376623 N, with values of chip samples <352ppb Au. However, no mineralization was found in the further CP-10-13 drill hole. Re-runs of the soils, and further soils northward, were not anomalous in gold, probably due to poor calibration in mass spectrometry as the 3 test analyses were only a third of known values. The later two decay samples 687 -688, and 683 - 682 northward, were anomalous despite the low values in the small outcrop. No conductor was found with the Beep Mat during rock sampling.

Please refer to the attached sample descriptions, analyses, and map.

Conclusions and Recommendations

This finishes the soil orientation sampling of the gold and zinc-gold occurrences of the 4-Corners area started in Oct 2006. As explained in previous reports no geophysics could be relied on, not even for gold-bearing pyrite which is non-conductive in CP-07-7, at 62 - 65 m. This left only soil sampling as exploration method, which was successful for zinc and especially associated cadmium, but still not reliable for gold.

Since gold occurs here separately in gold-bearing pyrite, chalcopyrite, and especially sphalerite, the only suitable method that detects even these minor gold occurrences, namely decay sampling as described above, should be extended over the wider area. It is also even better suitable for zinc-cadmium, is simpler to carry out, and may even work in the swamps as per the Dayton gold showing.

There is no need to cut lines, so that \$50,000 per square kilometer is estimated for decay sampling, which would find a deposit, if there is one.

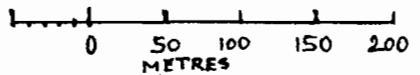

Respectfully submitted,

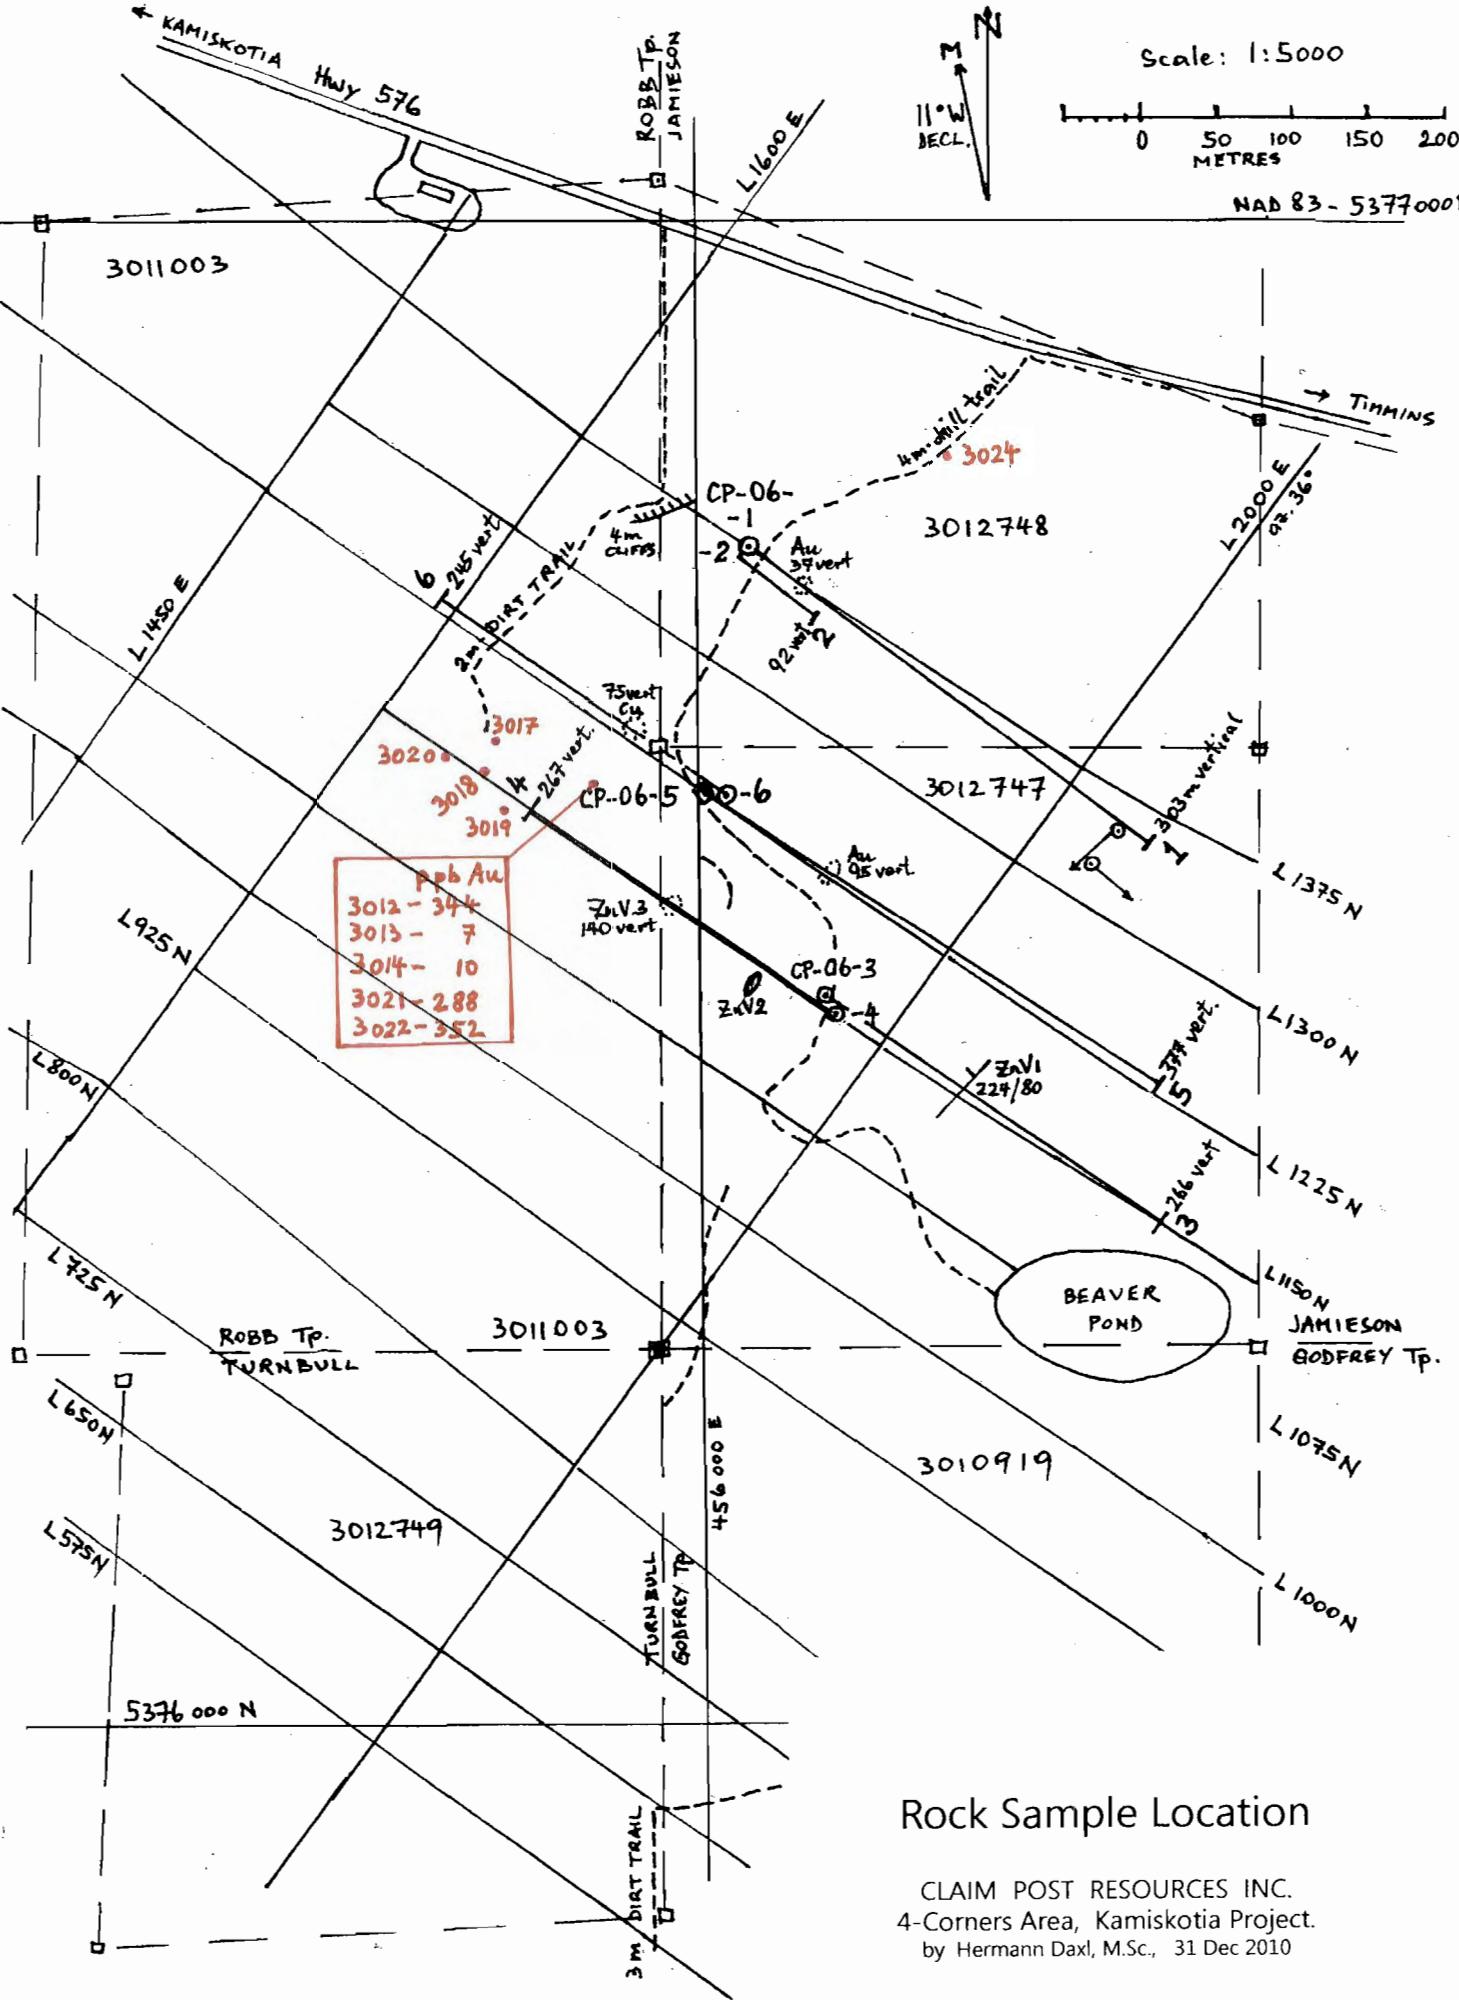

Timmins, 31 March 2011

Sample descriptions

Sample Location
NAD83 17U

3012, 3013 455931 E - 5376623 N (see also 3014, 3021, 3022)

At 3m wide ankeritized shearzone cleaved 285/70? in gabbro at east base of 100m outcrop area. Soil samples of 2008 show gold anomalies here.

8 % <1cm quartz-ankerite veins according to brown weathering, with trace of calcite and 1cm beige halo, crosscutting rock cleavage.
2 % pyrite as <1cm groups in fine-grained medium-green-gray brown-dotted (ankeritized?) gabbro with brown weathering crust. Nonmagnetic, no fizz by 10% HCl.

3012: 344 ppb Au, no Pt, no Pd.

3014 at 3012

3 % <1cm quartz-ankerite veins, 1 % pyrite, else similar to 3012.

3015 454382 E - 5378355 N (see also 3016)

All along west-side of roadcut where are about 5% dikes or stockwork 3016, no signals from Beep Mat BM4+. Excludes rocks of east side which are quite different massive finer somewhat magnetic black pyroxenite without dikes.

1 % <1mm pyrite cubes, grouped or disseminated, in dark green, coarse-grained pyroxenite, which is the wallrock to the dikes of 3016. Nonmagnetic, no fizz, fresh.

3016 at 3015

Granitic or quartz-K-feldspar-epidote, white-pink-green pegmatite <5cm thick dikes, with minor attached pyroxenite wallrock 3015. Nonmagnetic, no fizz, fresh.

3017 455867 E - 5376652 N (L1175N - 1670E)

Loose talus likely from low in cliff near trail, possibly a contact or fault.

5 % quartz-epidote veins, <1 % pyrite as selvage of veins or as fine-grained clusters. Dark green-gray pyroxenite, medium-grained, nonmagnetic, minor fizz of veins, fresh.

3018

455860 E - 5376630 N

On slope to southwest just west of soil gold anomaly. 3cm quartz-vein 165/35, other quartz-vein 20/80 crossing it. Somewhat brown weathered ankeritized ? outcrop.

30% quartz veining in dark green-gray aphanitic mafic, possibly a chilled gabbro contact. Nonmagnetic, locally minor fizz, barren.

3019

455873 E - 5376609 N (L1150N - 1705E)

At south-east end of cliff az. 145 from 3018 along L1150N. Down is southwest.

8 % <1cm quartz vein with very minor ankerite and without halo, locally <1 % 1mm pyrite cubes disseminated in wallrock. Fine-grained green-gray gabbro, ankeritized as per 5mm brown weathering crust. Nonmagnetic, no fizz.

3020

455836 E - 5376645 N (L1145N - 1650E)

Small knob south of L1150N, east of trail.

10% 12mm thick quartz-vein with minor ankerite. <1 % disseminated 1mm pyrite cubes in green-gray fine-grained gabbro which is ankeritized as per 5mm brown weathering crust. Nonmagnetic, some fizz only near veins.

3021

at 3012

4 % thin 1mm veinlets of quartz-ankerite-calcite locally containing much chalcopyrite. These veinlets have no halo and crosscut the 1% thicker veins described under 3012. Trace pyrite in gabbro wallrock.

288 ppb Au, no Pt, no Pd. Rerun pulp by Actlabs: 262 and 397 ppb Au, no Pt, no Pd.

3022

at 3012

1 % <1cm quartz-ankerite veins, trace pyrite, else similar to 3012.

352 ppb Au, no Pt, no Pd.

3024

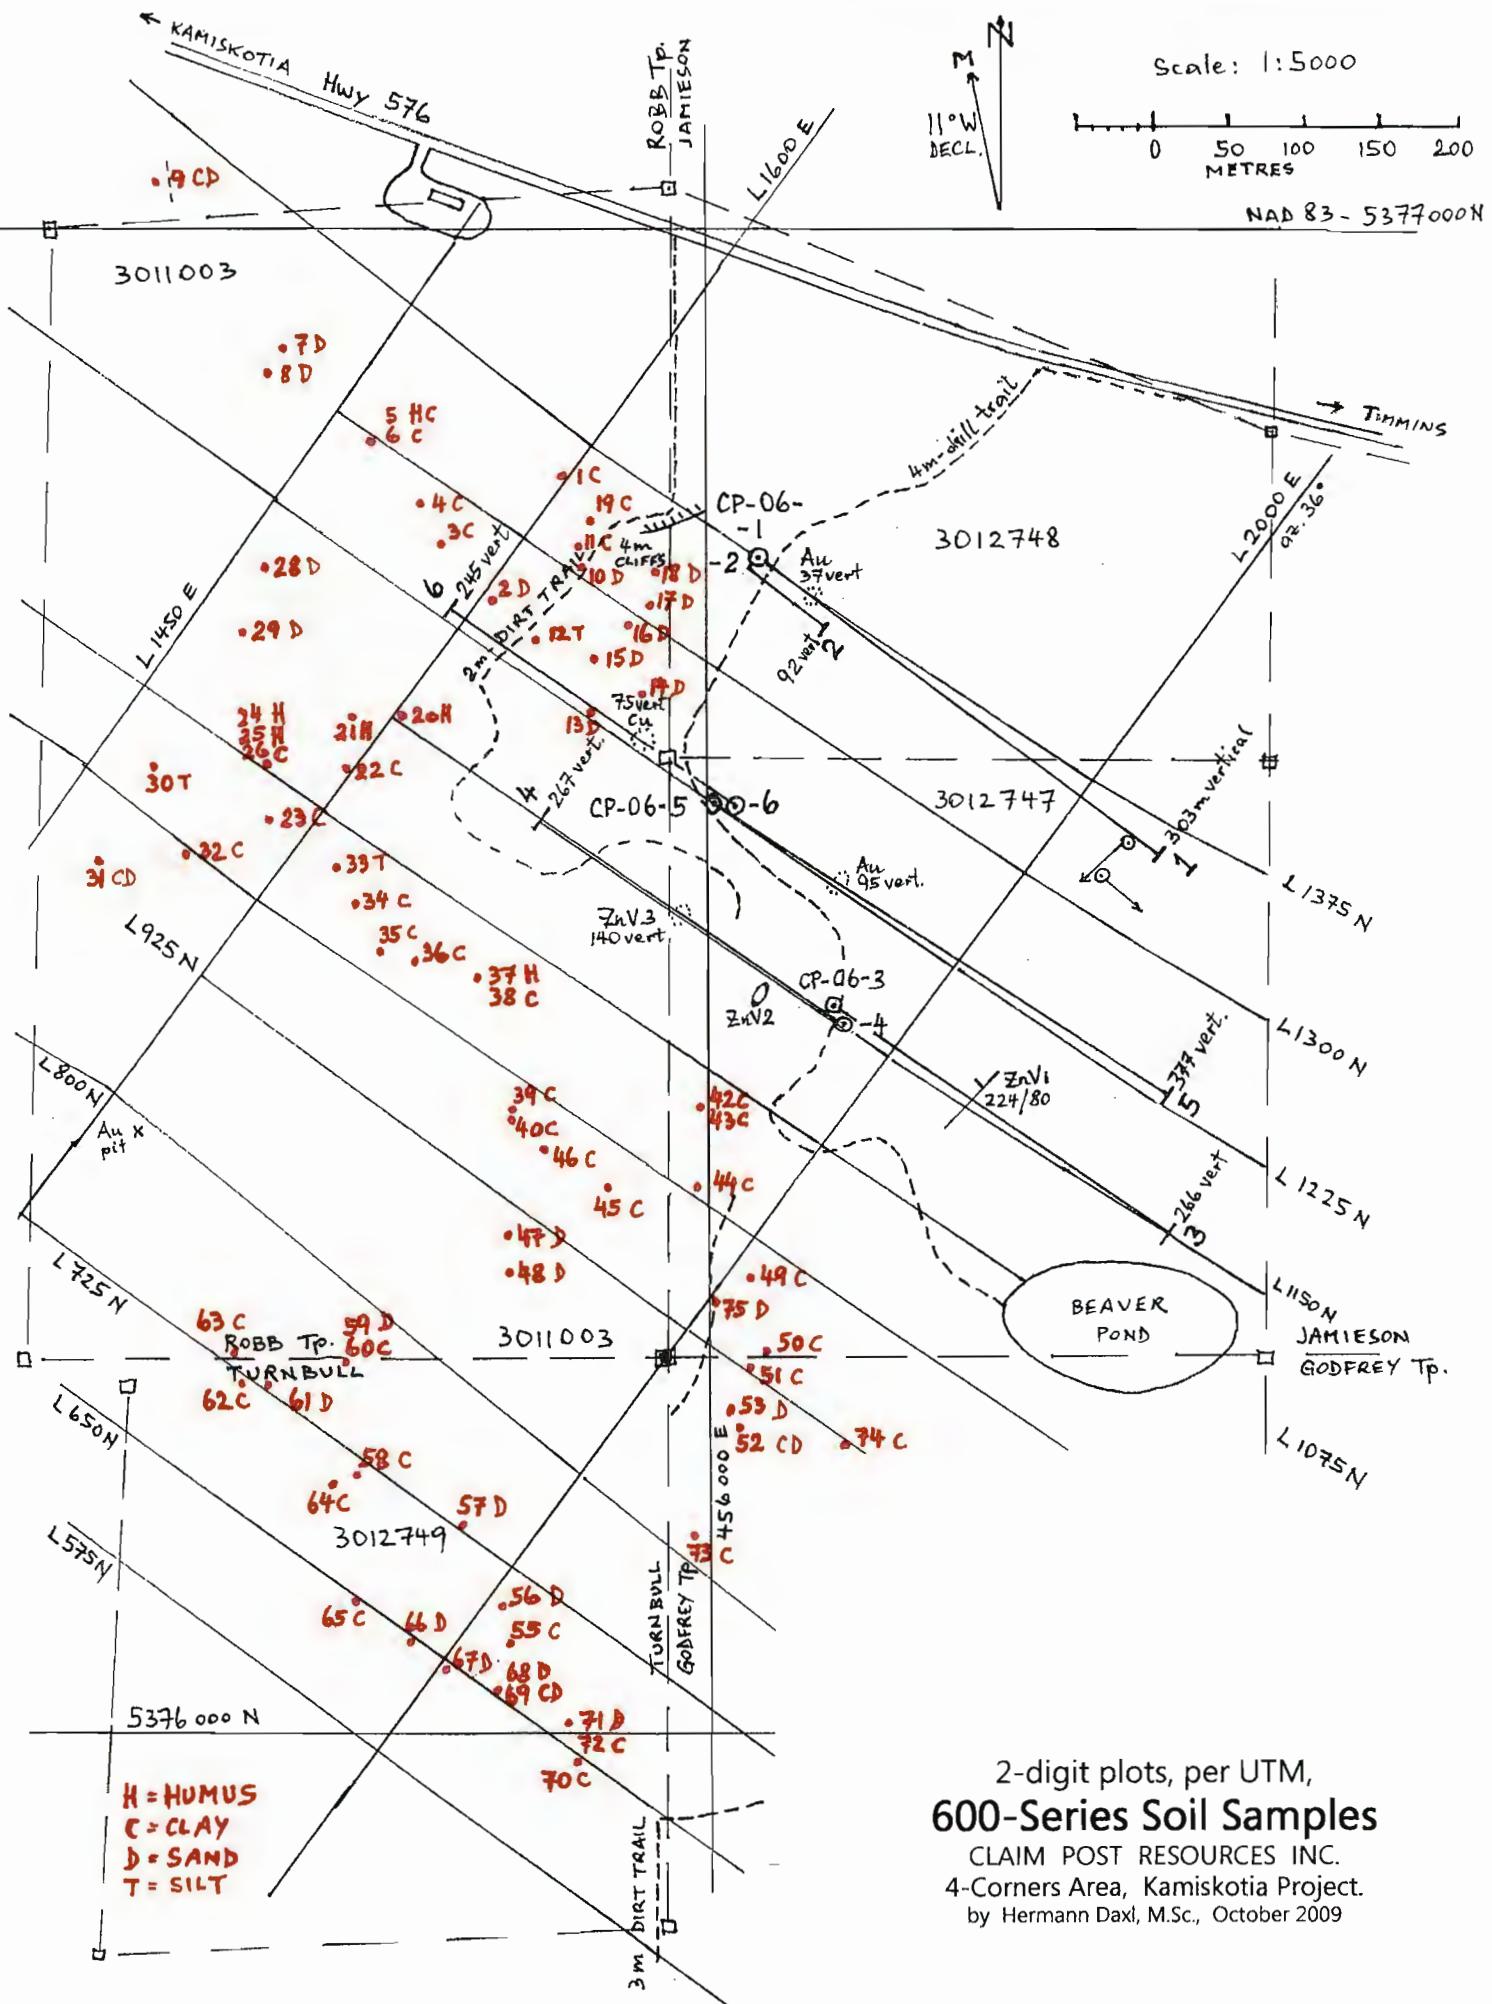

456165 E - 5376845 N

SE-side across new sand trail.

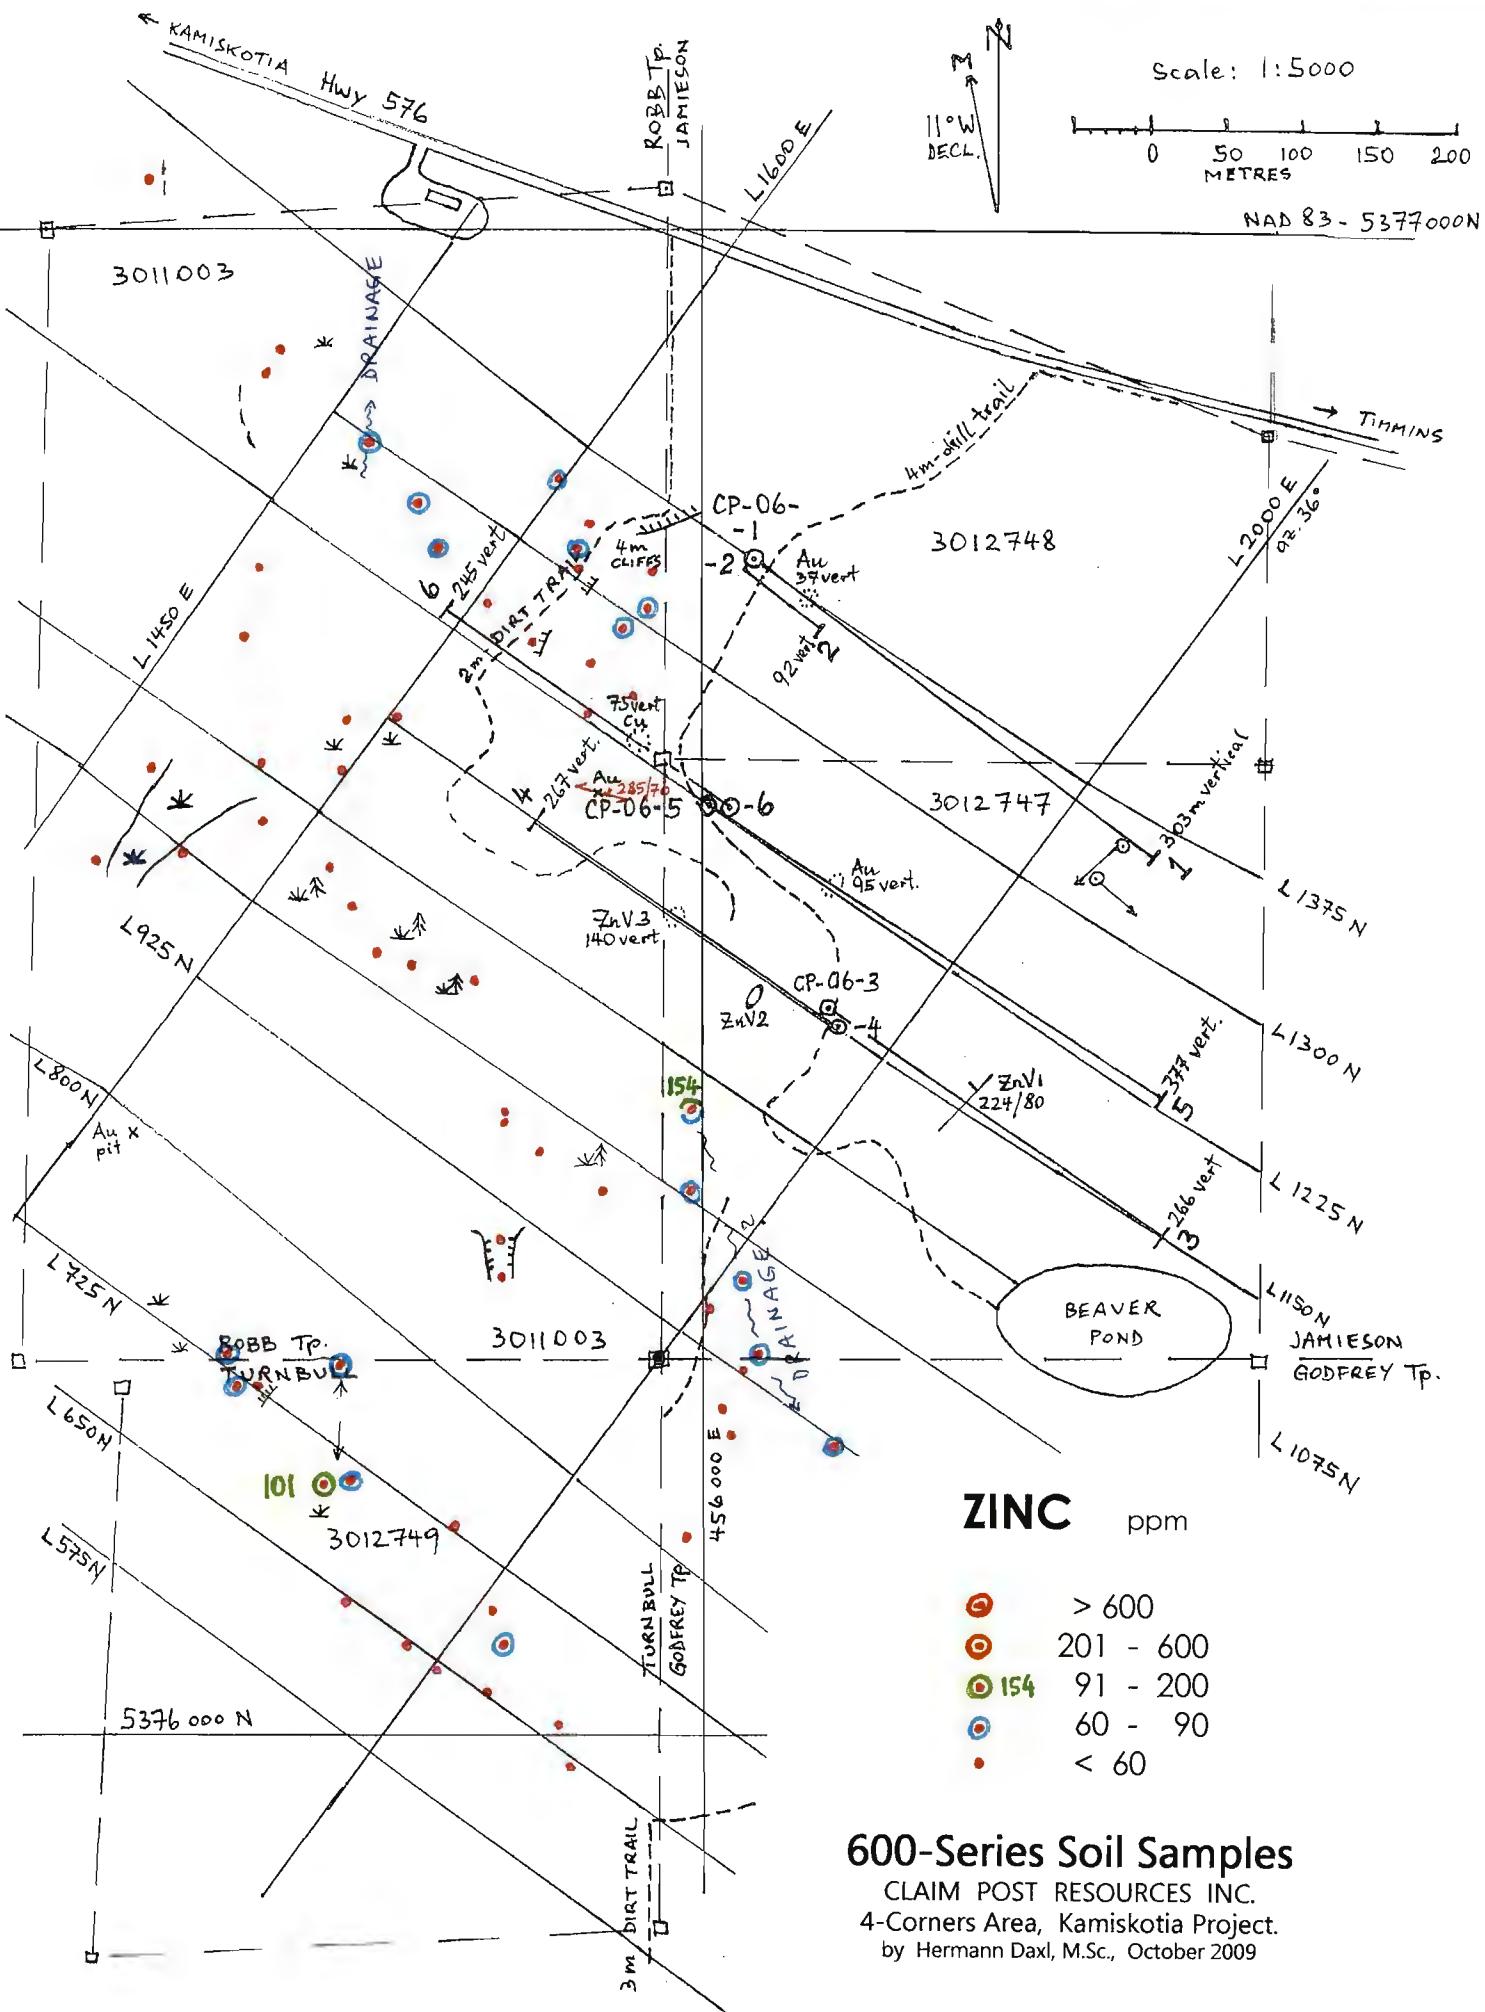

Meta-quartzarenite, <2mm round quartz grains visible in two beds with quartz matrix,
one of them with carbonate spots. 10% sheared, greenish-gray, mafic wallrock.
H=7, nonmagnetic, local moderate fizz of carbonate matrix.

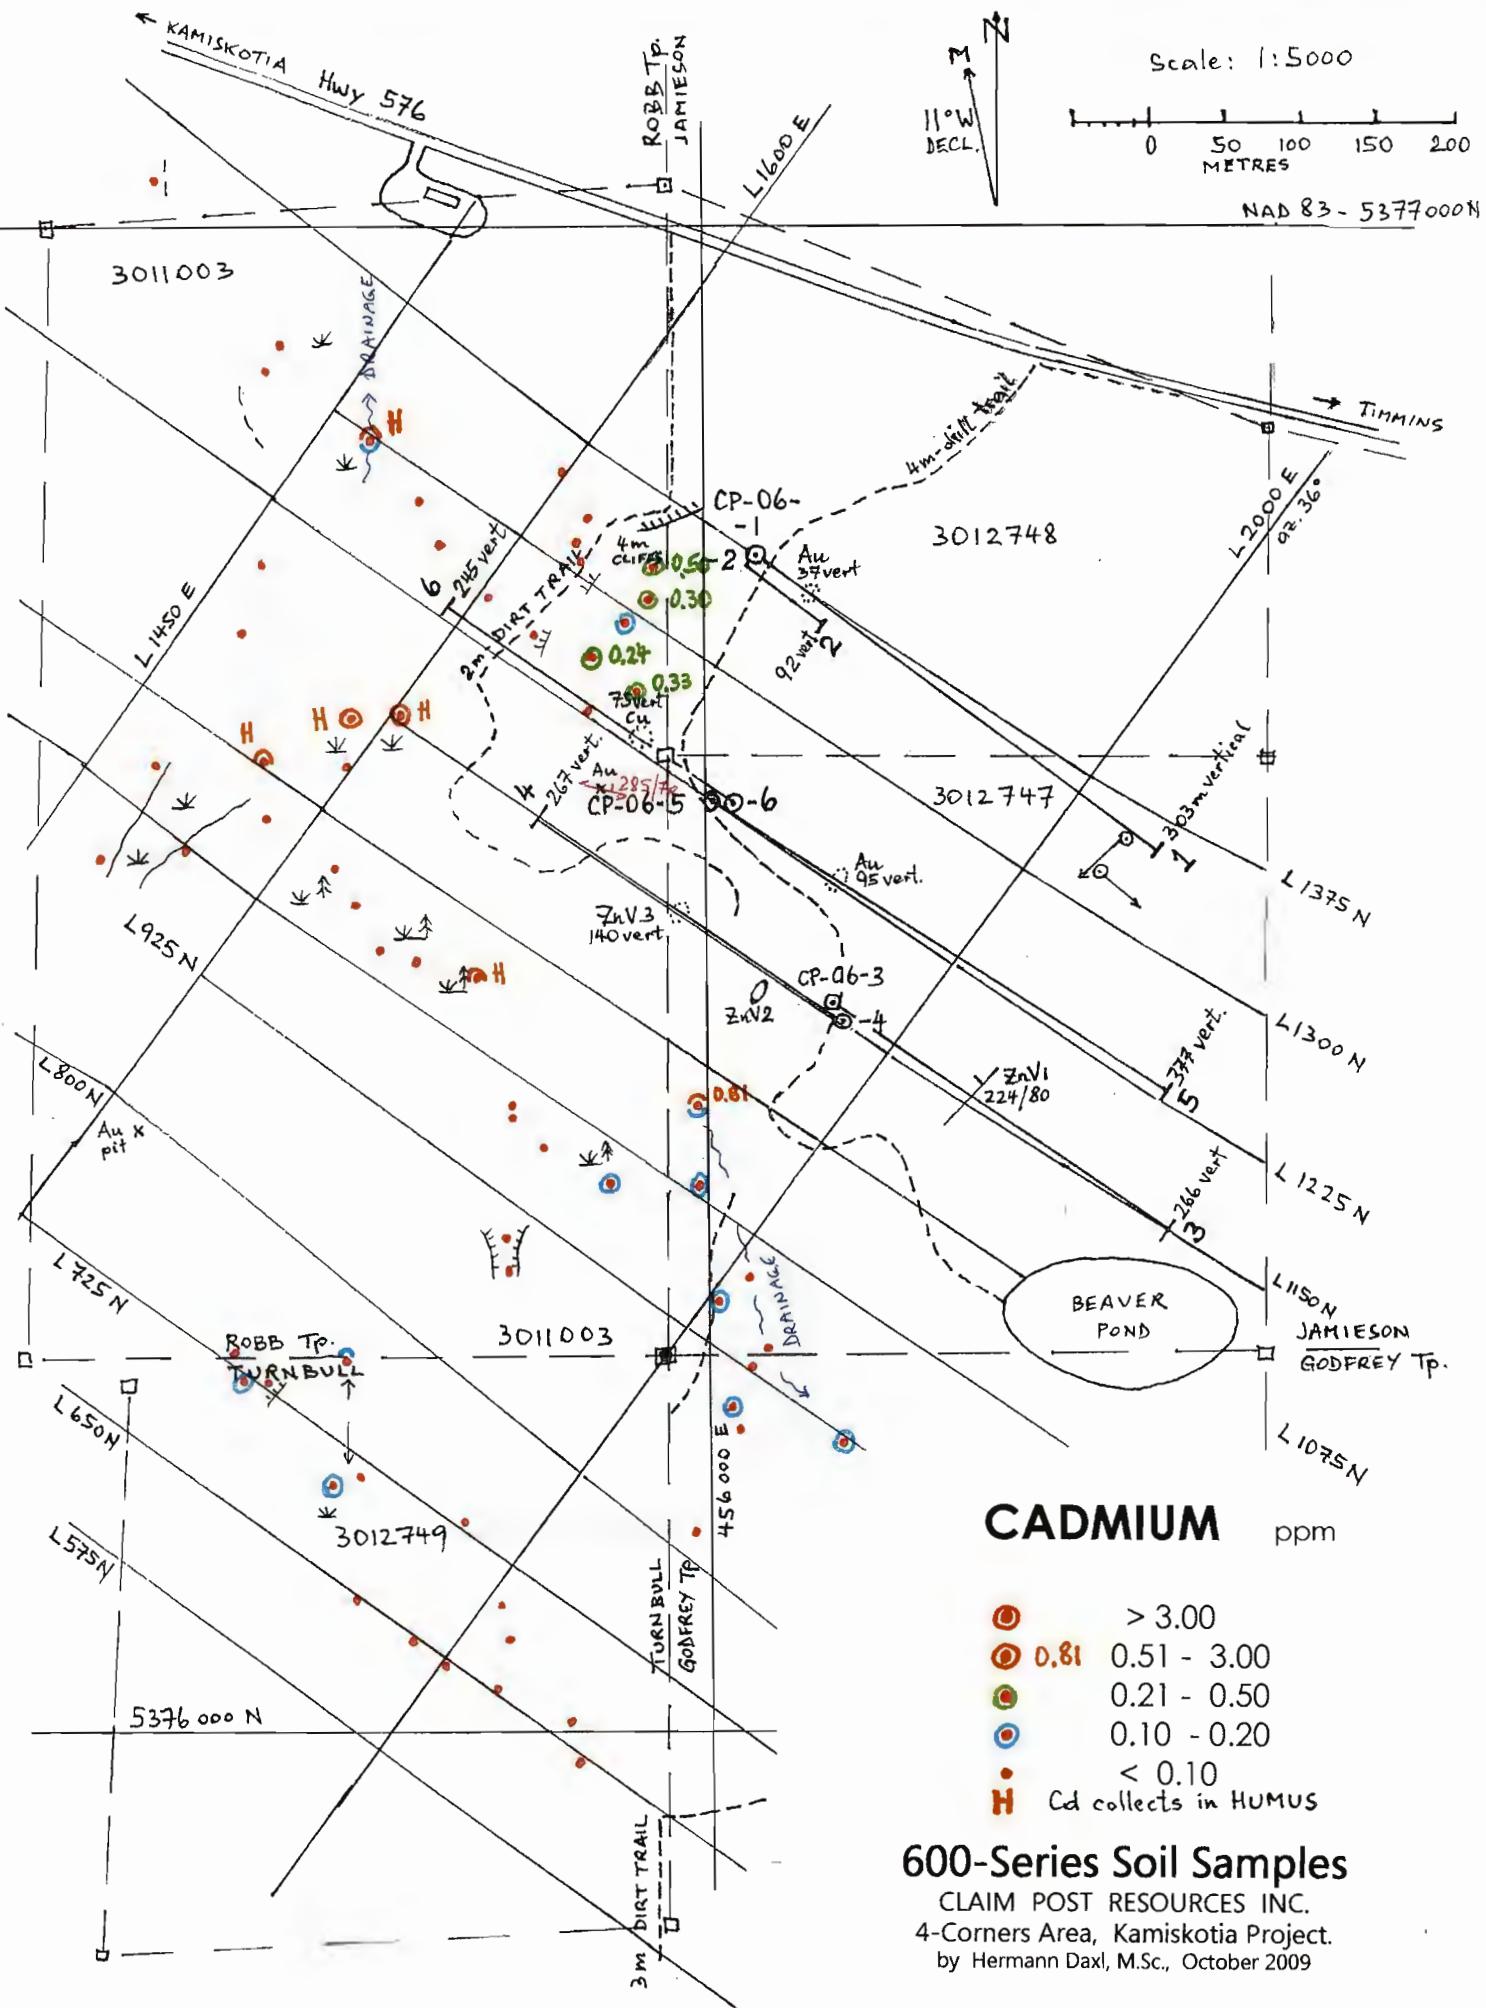

1 pyrite cube, 2mm, in quartzarenite. <5 ppb Au.

TEST	678	(PULP 496 - 474 = 641 = 654)										

CLAYS CRUSHED BY ROLLING BOTTLE, AVOIDED CRUSHING SAND GRAINS, OTHERS RUBBED.

ALL SIEVED < 125 µm with black plastic coffee filter, also humus.

PARTS OF ORIGINAL SAMPLES LEFT (except 675 > 125 µm only).

SOILS mostly of enriched zone or below humus where no enriched zone, but none contaminated by humus. Some were deeper due to disturbances by groundwater.

UTM and GRID all as measured or paced in field. PLOTS per UTM.

FIELD WORK 15 OCT 2009 TO 21 OCT 2009.

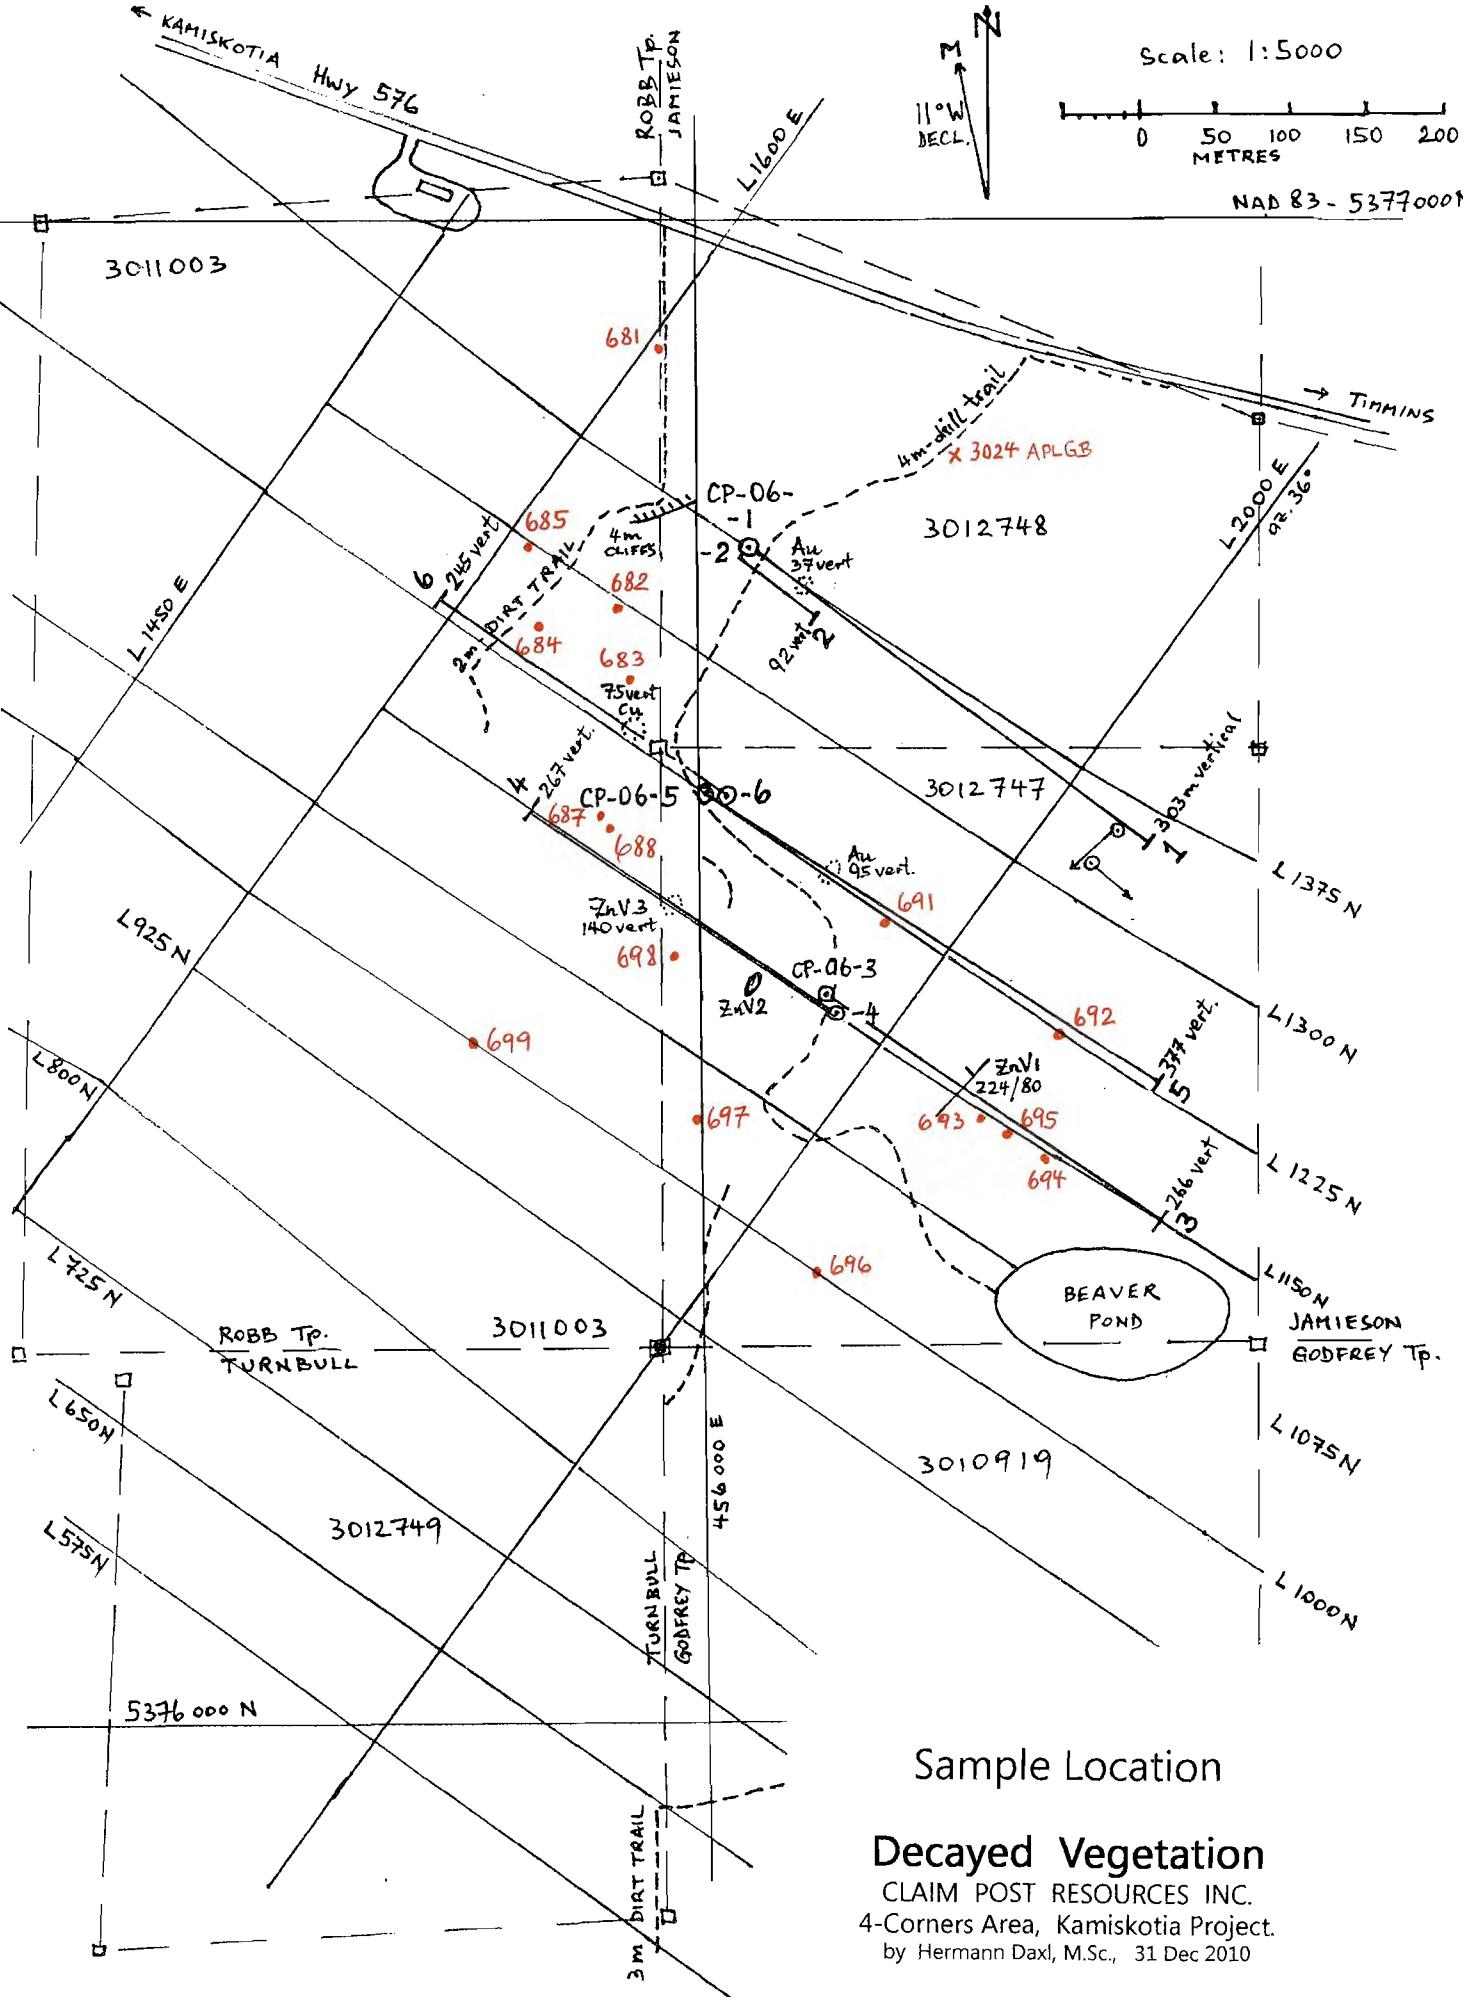

ALL NONRADIOACTIVE.

CERTIFICATE OF ANALYSIS

previously
24 Soil samples were submitted for analysis, namely A08-3049 and A08-8224.

The following analytical package was requested Code ID Enh INAA(INAAGEO)

REPORT A11-0165

To verify gold values because previous method of aqua regia - ICP/MS was found unreliable for gold. Nevertheless a gold pattern may be true, even if here not repeated.

This report may be reproduced without our consent. If only selected portions of the report are reproduced, permission must be obtained. If no instructions were given at time of sample submittal regarding excess material, it will be discarded within 90 days of this report. Our liability is limited solely to the analytical cost of these analyses. Test results are representative only of material submitted for analysis.

Notes:

For values exceeding the upper limits we recommend assays.

CERTIFIED BY :

A handwritten signature in black ink, appearing to read "Emmanuel Eseme". Below the signature, the text "Ph.D." is written in a smaller, capitalized font.

Next: Decay sampling and 2B-INAA of 1g packed in vials, to 0.1 ppb Au,
 may work despite the low-grade gold zones. Sieve to <250 mesh to concentrate encrustations.
 It would also preclude sparse gold particles which in other soils can be detrital.
 2B-INAA is possible only on (decayed) vegetation, i.e. excluding sand and clay.

CERTIFICATE OF ANALYSIS

9 Pulp samples were submitted for analysis. < 200 µm sieved swamp humus

The following analytical packages were requested: Code 1D INAA(INAAGEO)
Code UT-1-0.5g Aqua Regia ICP/MS

REPORT A09-7074

This report may be reproduced without our consent. If only selected portions of the report are reproduced, permission must be obtained. If no instructions were given at time of sample submittal regarding excess material, it will be discarded within 90 days of this report. Our liability is limited solely to the analytical cost of these analyses. Test results are representative only of material submitted for analysis.

Notes:

For values exceeding the upper limits we recommend assays.
Assays are recommended for values >10,000 for Cu and Au.
