## SUMMARY

This report describes an initial, 75-hole reverse circulation drilling program on the Ti-pa-haa-kaa-ning, Ontario, property of Northern Superior Resources Inc. The drilling was conducted in March, 2010 to evaluate a large gold grain glacial dispersal anomaly previously identified by surface till sampling. The drilling confirmed the surface gold grain anomaly and showed that it has at least four bedrock sources, most of which are enriched in arsenopyrite as well as gold. Geochemical analysis of the till and bedrock samples and a second phase of reverse circulation drilling are required to refine these four gold targets prior to diamond drilling.

## 2.

## INTRODUCTION

### 2.1

### Project Outline

In March, 2010, Northern Superior Resources Inc. (Northern Superior) drilled 75 reverse circulation (RC) holes on the company's Ti-pa-haa-kaa-ning (TPK) gold property in northern Ontario. The drilling was undertaken to evaluate a large gold grain glacial dispersal anomaly previously identified by surface till sampling. It was performed by the Timmins, Ontario branch of Bradley Brothers Ltd. (Bradley) and supervised by Overburden Drilling Management Limited (ODM) of Nepean (Ottawa), Ontario.

### 2.2

### Location and Access

The TPK property is located 470 km northeast of Thunder Bay and 190 km northeast of Pickle Lake, the nearest town with all-weather road access (Fig. 1). It lies north of Attawapiskat Lake within the traditional area of Neskantaga First Nation and is ~30 km northeast of the small (population ~350) community of Neskantaga, formerly known as Lansdowne House, located on the south shore of Attawapiskat Lake. Each winter, from February through March, Neskantaga is serviced by a temporary winter road leading 135 km eastward from a staging area on the Musselwhite Mine road northeast of Pickle Lake. Until recently, a 13 km ice road was also constructed northward across the lake to connect with a now-disused winter road (Fig. 2) passing 6 km east of the TPK property and

leading northeast to the First Nation community of Webequie on Winisk Lake. This route remains available to Northern Superior for transporting heavy equipment but the company is responsible for the annual cost of reopening the road. Access for lighter equipment, personnel and supplies is by float or ski-equipped fixed-wing aircraft or helicopter from Pickle Lake or Neskantaga. Both communities have daily scheduled air service from Thunder Bay.

Northern Superior formerly used Neskantaga as its base of operations for the TPK project but in January, 2010, established a fully-equipped base camp on Rowlandson Lake (Fig. 2) at the east end of the property in preparation for the RC drilling program. A new, 15 km winter road was opened northward from the Webequie road to the camp, passing through the eastern end of the drill area, and branch trails were cleared to the drill holes.

### **2.3                   Claims**

The TPK property is wholly owned by Northern Superior but, subsequent to the RC drilling program, Northern Superior granted Rainy River Resources Inc. (Rainy River) a three-year option to acquire a controlling 51 percent interest in the eastern part of the property within which the drilling was performed.

The property consists of 188 claims for a total of 39,778 hectares (Fig. 3). The RC drilling was conducted over 13 contiguous claims, Nos. 1203097, 1203098, 3019244, 3019253, 4217101, 4217102, 4217103, 4217105, 4221770, 4221771, 4221772, 4221773, and 4221774 (Table 1, Fig. 4).

## **3.                   METHODS AND COSTS**

### **3.1                   Program Design**

The RC drilling program was designed to locate mineralized bedrock sources beneath a glacially generated, southwest trending, 7 km wide gold-grains-in-till anomaly that Northern Superior had previously outlined by surface sampling on the eastern part of the TPK property (Fig. 5). The northeasternmost holes, near the glacial head of the anomaly, were drilled at a closer spacing (200 x

400 m spacing) than those further down-ice to the southwest (400 x 400 to 400 x 800 m). The program encompassed 75 drill holes (Fig. 4, Table 2) at an average depth of 8.0 metres for a total of 597.1 m. An average of 2.7 till samples was collected from each hole, followed by a single 1.5 m bedrock sample.

### 3.2

### Field Procedures

ODM measured the geographic co-ordinates (UTM, NAD83) of each drill site by GPS during initial layout and re-measured the final co-ordinates of the drill holes upon completion (Table 2). As well, imprecise GPS readings of the surface elevations of the drill hole collars were recorded and were later checked and revised by comparison with topographic maps and stereo air photos.

Three contractors and a variety of heavy equipment were employed during the road clearing, camp construction and drilling phases of the program. Outland Inc. of Thunder Bay used a plow truck for initial snow clearing on the ice road across Attawapiskat Lake and, with assistance from Neskantaga First Nation, constructed and operated the camp at Rowlandson Lake (Fig. 2). North Star Air Ltd. of Pickle Lake employed snow groomers to complete the ice road across Attawapiskat Lake and re-establish the section of winter road north of the lake. Bradley used a Caterpillar wide-pad D-6 bulldozer to clear the new access road and drill trails. Their RC drill rig was mounted and enclosed on a wide-tracked Nodwell carrier for all-terrain mobility and all-weather operation. Water for drilling was hauled from nearby lakes and creeks using a smaller Bombardier Muskeg tractor.

The reverse circulation drilling system used to sample overburden consists of specially designed coaxial piping and tricone bits (Fig. 6). Air and water are injected between the two pipes to the bit, and clay to pebble-sized sediment particles and cuttings up to 1 cm from boulders and bedrock are flushed instantly through the centre pipe to surface where they are continuously monitored and systematically described to produce a stratigraphic log (Appendix A). The -2 mm fines and a split of the +2 mm cuttings are collected in paired settling buckets from which samples weighing approximately 10 kg are extracted. Fine silt and clay suspended in the bucket overflow settle in a special tank and the water is recirculated down the drill hole. The 75 RC drill holes were prefixed TPKRC10 (for TPK property, 2010) and were numbered consecutively as drilled. The samples from each hole, whether of till, sand and gravel or bedrock, were also numbered consecutively (e.g. TPKRC10-63-01 to 05 for the five samples from Hole 63).

### **3.3      Sample Processing and Gold grain Observation Procedures**

The bedrock samples were sieved at ODM's laboratory to obtain a subsample of coarse (+2.0 mm), clean cuttings for binocular microscope logging (Appendix B) to verify the preliminary field descriptions (Appendix A). A second subsample of the cuttings was reserved for possible geochemical and whole rock analysis.

The till samples were processed using the procedures shown in Figure 7 which are designed to progressively reduce the bulk sample, expose the gold grains, concentrate the heavy minerals and eliminate any drill steel that would interfere with geochemical analysis of the concentrates should such analysis be required to qualify the gold grain counts. First, the sample is wet screened at 2.0 mm and a -2.0 mm table concentrate is prepared. Geological observations on the character of the sample are made during both the screening and tabling operations (Appendix C). The primary table concentrate is purposely large (typically 300-400 g) and of low grade (10-25 percent heavy minerals) in order to achieve a high, 80 to 90 percent recovery rate for all desired heavy minerals irrespective of their grain size or relative specific gravity. The gold grains, which are mostly silt-sized, are observed at this stage with the aid of micropanning and are counted, measured and classified as to degree of wear (i.e. distance of glacial transport; Fig. 8). Their gold assay value is also calculated (Appendix D). In addition to gold grains, the micropanning procedure concentrates pyrite (S.G. 5.01) and especially the heavier sulphides such as arsenopyrite (S.G. 6.07) and galena (S.G. 7.58). Therefore the approximate number of recovered grains of these minerals is also recorded. To obtain a uniform heavy mineral fraction suitable for geochemical analysis, should such analysis be needed to further assess any gold grain and other mineralogical anomalies, the -2.0 mm table concentrate is separated in the heavy liquid methylene iodide at S.G. 3.32. Undesirable magnetite and drill steel are then removed from the heavy liquid concentrate using a ferromagnetic separator.

### **3.4      Expenditures**

Qualifying exploration expenditures incurred in the RC drilling program are documented in Appendix E. Contract drilling, geological and sample processing costs totalled \$414,073 or \$693.47/m. Support costs, mainly for road clearing, camp operation, helicopter support and fuel, totalled \$937,471 or \$1,570.04/m.

## 4.

## RESULTS

### 4.1

### Quaternary Stratigraphy

Representative sections of the overburden encountered in the drill holes along the two lines indicated in Figure 4 are shown in Figures 9 to 10. The overburden along these two type sections ranges in thickness from 2 to 14 m and consists mainly of till. In low-lying areas and in swales in the uplands, the till is commonly overlain by glaciolacustrine clay which in turn is typically capped by a veneer of Holocene peat.

Only one till horizon is present but its thickness is very uneven, primarily due to variable drumlinization which is also reflected in the surface topography (Fig. 3). The till consists of up to 40 percent pebble to boulder-sized clasts in a fine sandy to silty rock flour matrix. The clast suite is dominated by granitic rocks derived from Archean plutons on and proximal to the property but generally also includes small (mostly pebble sized) carbonate and greywacke clasts derived from the distal Paleozoic and Proterozoic formations of the James Bay/Hudson Bay region to the northeast (Fig. 11). The proportion of these distal clasts may reach 50 percent in the core zone of thick drumlins but is generally <10 percent at the top and base of the drumlins and in areas of thin till between drumlins.

### 4.2

### Bedrock Geology

The RC drilling was concentrated on the northeastern half of the regional gold-grains-in-till anomaly (Fig. 5). This part of the anomaly overlies the granitoid Freure Lake Batholith on the north side of the narrow (<1 km) Bartman Lake Greenstone Belt (Fig. 12). The southern end of one drill traverse, along the new winter access road (Fig. 4), was on the Spero Lake Batholith south of the greenstone belt. However, no greenstones were intersected on this traverse; instead the Spero Lake and Freure Lake Batholiths are in direct contact. The contact zone is broadly mylonitized, suggesting that it is a major shear zone, possibly the regional-scale Stull-Wunnummin Fault which extends from the James Bay Lowland westward to Manitoba (Stott 2008). Significant shearing was also observed in some holes drilled further north in the Freure Lake Batholith. These shear zones are locally mineralized

with minor pyrite, pyrrhotite or arsenopyrite (Appendices A, B). The northern part of the Freure Lake Batholith consists of white, coarse-grained quartz monzonite whereas the southern margin, adjacent to the greenstone belt, consists of pink, aplitic to porphyritic leucogranite (Appendix B).

#### **4.3 Gold Grain and Arsenopyrite Content of the Till**

Most of the till samples obtained from the RC drill holes, like the surface samples previously collected by Northern Superior (Fig. 5), are anomalous in gold grains. In addition, many samples are anomalous in arsenopyrite and pyrite, an association that was not apparent in the weathered surface samples due to degradation of any contained sulphide minerals by post-glacial oxidation. The average gold grain content per till sample in each drill hole, normalized to 7.5 kg of processed -2.0 mm till matrix to correct for variations in sample size and texture, is shown on Plan 1 and normalized arsenopyrite values are shown on Plan 2. The distribution of gold and arsenopyrite grains in the till in the RC drill holes clearly shows that the previously identified surface gold grain anomaly (Fig. 5) has at least four separate bedrock sources rather than a single source at its head and that most of these sources are mineralized with both gold and arsenopyrite.

#### **5. CONCLUSIONS AND RECOMMENDATIONS**

The mineralogical data obtained from the till samples collected from the RC drill holes indicate at least four significantly mineralized areas in the bedrock beneath the regional-scale gold grain glacial dispersal anomaly that was previously outlined by surface sampling. However, the hole spacing was not sufficient to prepare these targets for diamond drilling and no RC drilling was done on the southwestern, down-ice half of the regional anomaly. The following additional work is required to fully refine the indicated drill targets and assess the untested portion of the gold grain dispersal anomaly:

1. Analysis of the bedrock samples for gold, arsenic, other potential pathfinder elements, major oxides and trace elements.
2. Geochemical analysis of the till heavy mineral concentrates for gold, arsenic and other potential pathfinder elements.

3. A second phase of RC drilling, including ~40 infill holes at 100 to 200 m spacing on the newly defined targets on the northeastern half of the regional anomaly and ~60 holes at 400 m spacing on the untested southwestern half of this anomaly.

The estimated cost of this work, based on the unit costs experienced in the initial RC drilling campaign, is:

<u>Task</u>	<u>Cost (\$Cdn)</u>
Bedrock analysis: 75 samples @ \$70 per sample	5,250
Till heavy mineral analysis: 200 samples @ \$35 per sample	7,000
RC drilling: 100 holes @ \$12,000 per hole	<u>1,200,000</u>
Total:	1,212,250

It is expected that the above work will lead to a major program of diamond drilling. This drilling should be conducted in winter to allow testing of lake-covered targets.

**CERTIFICATE – Stuart A. Averill**

I, Stuart A. Averill, residing at 192 Powell Avenue, Ottawa, Ontario, Canada hereby certify as follows:

That I attended the University of Manitoba at Winnipeg, Manitoba and graduated with a B.Sc. (Hons.) in Geology in 1969;

That I have worked continuously in the field of mineral exploration geology since 1971;

That I am President and principal owner of Overburden Drilling Management Limited, 107-15 Capella Court, Nepean, Ontario, an independent geological consulting company that I founded in 1974;

That I am a Member of the Association of Professional Geoscientists of Ontario and the Association of Professional Engineers and Geoscientists of Newfoundland and a Fellow of the Geological Association of Canada;

That this technical report is based on data gathered on the subject property by employees of Overburden Drilling Management Limited;

That I personally interpreted the data;

That I have visited the TPK Property on one occasion in August 2010;

That I directly hold or indirectly control 300,000 common shares of Northern Superior Resources Inc.

Stuart A. Averill, B.Sc. (Hons.), P.Geo.

Dated at Ottawa, Ontario this 5th day of April, 2011
