REPORT ON PHASE II

EXPLORATION OF THE MONTCLERG PROPERTY

IN CLERQUE, STOCK AND WALKER TOWNSHIPS, ONTARIO

FOR

MATAMEC EXPLORATIONS INC,

JANUARY 18, 2008

ALINE LECLERC, ogq 879

## EXECUTIVE SUMMARY

In 2006, Matamec Explorations inc. (Matamec) signed an option to acquire 51% interests in the canton Clerque property in Ontario belonging to Explorer Alliance Inc (Explorer), Janice Bonhomme and Bruce Durham.

The property was acquired after examining reports supplied by Mr. Lionel Bonhomme. Mrs Aline Leclerc, V.P. Exploration for Matamec and author of the present report, recognized in this property a strong potential for deep ore bodies along the main gold-bearing structure (Montclerg zone), as well as along another, less explored, structure further to the south (the Canamaz zone).

Indeed, after consulting the reports it quickly became evident that the principle auriferous zone, the Montclerg zone, was composed of numerous veins and stringers of quartz-carbonate with varying quantities of chlorite and/or tourmaline accompanied by traces to 5% of pyrite, pyrrhotite and/or arsenopyrite. More importantly, it also seemed quite clear that great potential remained unexplored at more than 150 vertical depth. Indeed, 98% of historic drilling efforts concentrated on the 0 to 125 depths with only few holes going beyond 150 meters. The property was therefore acquired with the intent to drill deep holes along the Montclerg zone.

It should also be noted that the numerous historic drill holes literally criss-cross the region, going from North to South, from South to North, from North-East to South-West and from South-West to North-East. Clearly, all this drilling was done without a firm understanding of the geometry of the auriferous veins composing the Montclerg zone.

Phase I of exploration therefore started in the summer of 2006 under the supervision of Dr. Ed Van Hees. Given the above, the campaign objectives were 1) to gain a better understanding of the vein structure and 2) to explore the Montclerg zone beyond the 125 meter zone. The area chosen for the study centered around section 49+00E, to the east of the Driftwood River, in a location where numerous old multi-directional drill holes intercepted equally numerous, high grade gold-bearing veins in the first 100 meters. Vertical drilling was used so as to allow measurements of true angle of stringers and veins on the core samples.

All nine (9) of the 2006 drill holes intersected the auriferous zones described in the historical reports. Gold values though, while present, were uniformly under historic values. Furthermore, only three (3) of the nine (9) holes were drilled beyond 150 meters, namely holes 6, 7 and the deepening of hole 2. It should be noted though that these three holes did intersect a larger and well-mineralized structure around the 300 meter mark. It is this author's considered opinion that this structure fully warrants additional drilling, both laterally and along strike. Detailed results of Phase I are included in Dr Ed Van Hees' report of February 2007.

Phase II of exploration, executed during the months of February and March 2007, was concerned solely with deep exploration. This latest phase targeted a sector west of the

Driftwood River where old drill holes indicated interesting grades near surface and one deeper hole #26 returning also good gold intersection.

Fortunately or unfortunately, the first holes drilled through a nice quartz-feldspath porphyry, very well altered, which contained veins and stringers of quartz with small amounts of carbonates, chlorite, occasional tourmaline, the whole mineralized with fine arsenopyrite. The drilling campaign now centered on tracing this porphyry over the first 150 meters of depth. At the end of the campaign, the target porphyry was encountered in three (3) of the six (6) holes drilled, with only the first hole returning interesting values.

These two drilling programs did allow Matamec to define a host rock stratigraphy at Montclerg which differs markedly from the one reported in Pentland Firth Ventures Ltd 1999 compilation report. That report described the Montclerg zone as a “variably carbonatized mafic fragmental tuff-agglomerate in contact with a sequence of variolitic pillowed mafic volcanics”. This mafic sequence was “part of an east-west trending belt of intercalated (tholeitic) mafic volcanics and minor (komatiitic) ultramafic volcanic flows of the favorable Tisdale Assemblage stratigraphy”. As soon as the first hole of 2006 was drilled, this version of events had to be reconsidered due to the presence of a layer of acidic lavas intercalated in the basic sequence. In addition, the mineralized structures, the veins and stringers, were equally hosted in the acid lavas and in the basalts (please refer to Ed Van Hees' report and geological sections for details). It should be noted though that before the Pentland report, old drill logs did indicate the presence of rhyolite and porphyritic felsic intrusions.

Following the discovery of acid lavas, closer mineralogically to the Texas Gulf mine units than to basaltic sequences, a number of studies were done by Matamec and their partner Explorer Alliance to understand the geological context of this mineralization. In addition, the Ontario Geological Survey began a geochronological study of these rocks in early 2006. In 2007, Tim Barrett of Ore Systems consulting started a geochemical study of cores from Matamec's 2006 and 2007 campaigns as well as Pentland's 1999 campaign, all of which are stored at Matamec's Timmins facility. This latest study by Tim Barrett is part of an independent report which will soon be made available.

At the conclusion of these two drilling campaigns, Matamec has gained its 51% interest in the property. The author of this report feels that if there is to be continued drilling at Montclerg, it should prioritize targets under the 150 meters level in the Montclerg zone, as well as targets along the Canamax zone to the south.

## 1 - INTRODUCTION

In 2006, Matamec optioned the Montclerg property for its potential at depth along the main Montclerg zone as well as its potential along other, less well known zones such as the Canamax zone, located more to the south along the Pipestone fault.

During the summer of 2006, phase I drilled nine (9) holes in the main zone, three (3) of them bottoming beyond 150 meters. Positive results were obtained from these three deeper holes and so a second drilling program was scheduled for February of 2007. This report details its results.

## 2 - LOCATION AND ACCESS

The property is situated at the eastern end of the world famous Porcupine gold camp in Timmins, Ontario (**Figure 1**). More precisely it covers part of the Clerque, Stock and Walker townships and straddles the boundary between the Porcupine and Larder Lake mining divisions (**Figure 2**).

The village of Monteith is two (2) kilometres north and downtown Timmins is 60 kilometres to the west-southwest. Secondary road 577, leading north from highway 101 to highway 11, crosses the east part of the property while highway 11 itself borders its northern side. Bigelow drive, a lot road running east-west, gives access to the northwestern side of the property (**Figure 2**).

## 3 - PROPERTY

The property is composed of 25 contiguous freehold patented and staked claims of approximately 402 hectares. The land parcels that make up the Montclerg property proper include: (**Figure 3**)

PARCEL/CLAIM	PART LOT	LOT	CONC	TOWNSHIP
6316 SEC	S ½	1 & 2	1	Clergue
6705 SEC	S ½	12	1	Walker
P-3003960	S ½ of S ½	3 & 4	1	Clerque
P-3003969	N ½ of N ½	2	6	Stock
P-3010199	S ½ of N ½	2	6	Stock
P-3010200	NW ¼ of N ½	1	6	Stock
P-3010201	NE ¼ of N ½	1	6	Stock
P-3010202	SE ¼ of N ½	1	6	Stock
P-3010203	SW ¼ of N ½	1	6	Scotk
P-1213753	Land under Griftwood River (1 unit)			

The property includes both patented, mining rights only (MRO) and staked claims, with 21 claim units located in the Porcupine mining division and 4 claim units located in the

Larder Lake mining division. The property includes two surveyed parcels of land that make up 12 of its 25 claim units. The rest of the claims are staked and have not been surveyed.

#### **4 - TOPOGRAPHY**

The area is topographically flat, due mostly to the extensive clay cover deposited by the Barlow-Ojibway glacial lake. Indeed, numerous farms take advantage of the clay overburden of the area. Driftwood River, a plentiful source of water, crosscuts the property in a north-south direction.

#### **5 - PREVIOUS WORK**

This section is completely taken from ED Van Hess' 2006 report.

Gold was discovered on the main Montclerg zone in 1938 when a landslide on the east bank of Driftwood River exposed arsenopyrite-bearing quartz veins that carried 4 to 7 g/t of gold (Yule, 1999). Montclerg Mines Limited was organized and exploration of the main property over the next five decades by Montclerg Mines Limited, Newmont Exploration, Howey Mines, Anglo-Huronian and Consolidated Montclerg Resources, eventually resulted in a 1,600 m long by 130 m wide alteration zone being defined within which occur a number of mineralized zones (see Bath, 1990 for details of the exploration history). These zones were estimated to contain 336,668 tonnes of mineralization grading 4.106 g/t of gold (original non-NI43-101 compliant estimate made by mining engineer A.S. Banes in 1986 was 371,000 tons containing 0.132 ounces of gold per ton). The records for much of this work are incomplete at best (Yule, 1999).

The most recent exploration of the Montclerg property was undertaken by Canamax in 1987. They completed linecutting, a magnetic survey and a total of 4,152 metres of drilling in 19 holes on three targets (Clavos Extension, Montclerg East and Montclerg West). Most of the drill footage was used to test for an extension of the Clavos Zone, located some 8 kilometres west of the property. The program discovered a mineralized arsenopyrite-bearing porphyritic intrusive unit thought to be associated with the Pipestone Fault along the southern edge of the property. This zone contains gold values up to 4.44 g/t over 4.0 metres and has subsequently become known as the Canamax Zone.

Pentland Firth Ventures Ltd. began exploring the property in early 1994 and terminated the option in 1999. They conducted a magnetic and VLF-EM survey on newly cut grid over the entire property. Channel sampling was completed on the quartz veins exposed in the discovery outcrop near the Driftwood River as part of a study to determine the orientation of the different vein sets and their gold contents. Orientation Induced Polarization and Enzyme Leach Soil Surveys were conducted over part of the main Montclerg zone. A total of 8 diamond holes were drilled on the property with 4 each on the Canamax and Montclerg Zones (Yule, 1999).

## 6 - REGIONAL GEOLOGY

This section is completely drawn from Ed Van Hess' 2006 report.

The Montclerg property is located at the eastern end of the Porcupine Gold Camp in the southwestern portion of the Archean age, Abitibi Greenstone Belt (**Figure 4**). The Porcupine camp has produced in excess of 65 million ounces of gold (MNDM website) of which >98% has been mined from the Tisdale assemblage rocks that lie between the regional Porcupine-Destor and Pipestone Faults. The Tisdale assemblage of metavolcanic and related intrusive rocks have compositions that range from ultramafic near the base of the volcanic pile, through mafic and intermediate to felsic at the top. Related clastic metasedimentary rocks derived from the metavolcanic rocks also occur in the area. All these rocks are cut by younger Paleoproterozoic diabase dykes (Berger, 2000).

Rocks in the Montclerg area have been subdivided into 4 different assemblages. From north to south these are the Duff-Coulson-Rand, the Kidd-Munro, the Hoyle and the Bowman assemblages. The regional Pipestone Fault separates the Kidd-Munro from the Hoyle assemblage and the regional Porcupine-Destor Deformation Zone separates the Hoyle and Bowman assemblages.

## 7 - PROPERTY GEOLOGY

This entire section is also drawn from Ed Van Hess' 2006 report.

The author relied largely on mapping and data compilation efforts by previous explorationists for the initial property geology data used to layout the current drilling program because deep glacial overburden covers most of the Montclerg property (**Figure 5**).

### Mineralization Type

The style of mineralization present in the Montclerg Zone was studied by Pentland Firth geologists using three complete drill holes stored at the offsite MNDM core farm in Timmins (Yule, 1999). Their observations that elevated gold values are closely associated with finely-disseminated wallrock-hosted sulphide zones that have typical sulphide concentrations of 1% with local concentrations between 3 and 10%, were confirmed during examination of the same core by the author. Pyrite and arsenopyrite are the dominant sulphides present in the alteration halos that occur around sulphide-bearing quartz veins and stringers. The pyrite and arsenopyrite are typically euhedral with the pyrite and the arsenopyrite crystals generally being  $\leq 0.5$  and  $\leq 2$  mm in size, respectively. Geochemically anomalous gold values are present wherever these sulphides

occur and higher gold grades generally coincide where sulphide concentrations are greater than 5% and have a high arsenopyrite to pyrite ratio.

Weak wallrock alteration of the silicate minerals coincides with the sulphide halo around the veins and veinlets. Light- to lime-green coloured sericite alteration appears to be common in the wallrocks. Some graphite may also have been deposited with the sulphides because there appear to be "grey zones" around some of the veins, like that present in the Hoyle Pond deposit.

### **Historic Tonnage Estimate**

A number of previous tonnage estimates exist for the Montclerg property, the most recent done by mining engineer A.S. Bayne in 1985. He estimated the Montclerg resources at 408,100 t. and 4.53 g/t Au.

Ed Van Hess successfully located a copy of Bayne's ore reserve report in the Goldcorp office, but the plans that should have accompanied said report could not be found. It is therefore impossible to validate the tonnage and grade estimates made by Bayne. In final analysis, these resources do not therefore comply with NI 43-101.

## **8 - WORK DONE BY MATAMEC EXPLORATIONS INC.**

### **2006 - PHASE I**

Matamec's first exploration campaign was based mainly on Baynes' 1985 conclusions and was designed to:

- Improve the overall understanding of the mineralization,
- Validate the feasibility of open pit mining in the Upper Montclerg Zone (<200 meters depth),
- Find other mineralized zones at depths less than 400 meters, and to
- Increase historical resources set at 408,100 t. and 4.53 g/t Au.

Under the supervision of Ed Van Hes, nine (9) holes were drilled during the summer of 2007 near section 49+00E. He wrote: "the assay results obtained from this campaign were encouraging. When these are combined with our new understanding of the orientation of both the shallow (<100 m) and deep (>300 m) mineralized zones, we can begin to see the potential in the Main zone. However, the spacing of holes, primarily as a fence on section 49+00 mE, precludes making any comments about the tonnage and grade estimates at this time."

The main observation of his report was that: "A shallow-dipping ( $20^\circ$ ) semi-massive mineralized body was encountered at a depth of >300 m. This body extends for at least 60 m and probably 90 m along its dip and has a bigger size and higher grade than any mineralization that has been discovered previously. The presence of a semi-massive

mineralized body beneath a lower-grade, near surface mineralized body suggests that additional higher-grade, semi-massive mineralized bodies could be present beneath other low grade mineralization found elsewhere on the Montclerg property.” Following that conclusion, he proposes that “a 2,500 m drill program should therefore be undertaken to test for comparable mineralization beneath the West of River Zone and to explore the lateral extent of deep mineralization in the Main Zone.”

Van Hess’s other observation is of prime consequence for exploration. He notes that : “Drill holes that penetrated the near surface mineralization in the Main Zone indicated that this body has a greater lateral extent than previously indicated by the existing drill hole sections.” Therefore, “The near surface part (<100 m) of holes drilled to explore the lateral extent of the deep Main Zone mineralized body should be sampled and assay results evaluated to determine if this part of the Main Zone has any open pit potential.”

## 2007 - PHASE II

After combining a compilation of all historic drilling with the results of the first campaign, it appears that the Montclerg Zone is a more or less continuously mineralized zone that extends 2,600 meters from section 40+00mE to 66+00mE . On the longitudinal section (**figure 6**) we can see the two level of mineralized bodies, from 0 to 125 meter deep and around 300 meters deep. Most of the historic holes were stop in the first level except for 2 holes the number 21 near section 49+00mE and number 26 around section 45+50mE

The second phase of exploration therefore aimed to confirm the continuity of the Montclerg zone on the West shore of the River (sections 45+00mE and 46+00mE) and to confirm that the gold mineralization on the Upper Montclerg Zone and at depth is similar to that in the area drilled around section 49+00mE during the first phase. Historic holes drilled near the West shore of the river showed well mineralized intervals near the surface and one hole mineralized at depth. Indeed, in previous drilling on sections 45+50mE and 46+00mE, the gold zone returned values up to 13.96 g/t Au on 4.60 meters; 19.79 g/t Au on 4.57 meters and 27.43 g/t Au on 1.52 meters (**Figure 7**). In February and March 2007, Matamec therefore followed Ed Van Hees’ first recommendation and drilled six holes on the West shore of the river.

The coordinates of the six holes are shown in the table below:

Hole	Line	Station	Dip
Sondage 1	Ligne 45+50E	0+30N	90
Sondage 2	Ligne 45+50E	0+90N	90
Sondage 3	Ligne 46+25E	0+60N	90
Sondage 4	Ligne 45+50E	0+00N	90
Sondage 5	Ligne 45+20E	0+30N	90
Sondage 6	Ligne 44+90E	0+00N	90

The first hole encountered a quartz-feldspar porphyry from 18,45 to 161,15 meter. This unit was well altered and well mineralized with pyrite and arsenopyrite. A great quantity of small quartz-carbonate stringers, ranging from 1 mm to a few cm, crosscut the intrusion. They show different dips, though the majority is sub horizontal (70 to 90 degrees to core axis). Contact with the dacitic rocks to the north is sub-vertical (15 degrees to core axis) and contact with the rhyolitic rocks to the south is also sub-vertical (10 degrees to core axis). The rhyolitic rocks to the south seem to have the same chemical composition as the porphyry and may be genetically related. That rhyolitic unit also presents the same alteration and mineralization as the porphyry, though no gold values were found in that unit for hole 1. The porphyry is aphanitic for 1 cm true width near its lower contact with this rhyolitic unit.

The porphyry in that first hole was entirely sampled and assayed for gold based on the highly developed alteration, the great quantity of quartz-carbonate stringers present and the abundance of sulphide. Small quantities of gold were indeed found in all intersections assayed, with 25% of them reporting higher than 1,00 g/t Au. Those higher values defined two low grade zones, first from 44 to 75 meters (1,35 g/t on 31 meters) and then from 118,90 to 143,50 (0,99 g/t on 30,6 meters). Two other intersections were found also in that hole, one from 34,40 to 34,80 meter (1,17 g/t on 0,40 m.) and the last one from 266,30 to 267,50 (1,89 g/t on 1,20 m.).

The second hole, 60 meter to the north on the same section, also intersected that same porphyry from 163,13 to 205,01 meters but this time with less alteration and less mineralization. Most of the intersection was sampled and assayed. Unfortunately, all assays were under 1 g/t except for one in the overlying mafic volcanic unit, close to the upper porphyry contact, from 162,63 to 163,13; giving 5,28 g/t on 0,50 m. The underlying rhyolitic unit returned 2 assays higher than 1 g/t Au: From 217,10 to 217,70 (1,34 g/t on 0,6 m) and from 223,80 to 224,63 (1,75 g/t on 0,83 m).

The third hole, 75 meter to the East, was stopped while still drilling the overburden : the casing crumpled and broke against a big boulders at 24 meter depth. That hole was originally planned to intercept historic Au values found at depth in hole # 26 (**Figure 7**). Unfortunately, Matamec's hole number three never reached its deep target and the whole program thereafter shifted on a quest to follow the porphyry.

The fourth hole was made on the same section as holes 1 and 2, 30 meter to the south of hole number 1. It probably intersected the porphyry at the beginning of the hole, from 21,40 to 27,00 meter, just after leaving the overburden. The rock there was too weathered and broken to be certain of its exact nature though. The hole thereafter stayed in rhyolitic rock, all the way down to the end at 161 meters. Most of it was sampled and assayed and only one intersection returned higher value than 1 g/t Au , namely 2,20 g/t over 0,50 m. from 116,50 to 117,00 meter.

The fifth hole was drill 30 meters west of hole 1. It was planned to give the best possible intersection of the porphyry unit. After 10,93 meters of overburden, it did indeed enter

porphyry, keeping with it until 155,03 meter. This specific length of porphyry was unfortunately also less altered and less mineralized than the original intersection in hole 1. Only 5 assays returned higher value than 1,00 g/t, namely from 49,54 to 50,50 meters (2 assays giving 2,13 g/t on 0,96 meter), from 60,00 to 61,00 meters (one assay giving 1,68 g/t on 1,00 meter), and from 90,35 to 91,00 meters (one assay giving 2,30 g/t on 0,65 meter). The same altered acidic unit was encountered under the porphyry. It featured an intersection of 2,05 meter running 1,94 g/t in a highly sericitized section with abundant arsenopyrite.

The sixth hole was drilled 60 meter west of hole 4. After 14.32 meters of overburden, it crosscut the fragmental rhyolitic unit until 176,34 meter of depth. Followed a more mafic unit until the end of hole at 191 meter. A few pyrite and arsenopyrite zones (1-7%) with quartz-carbonate stringers were assayed for gold. The first zone, extending from 95,37 to 98,45 meters, reported 1,42 g/t on 3,08 meter while the second zone, extending from 122,00 to 122,50 meters, reported 1,50 g/t on 0,50 meter.

All the 5 holes are presented in 3 sections. The section 45+50mE with 3 holes the #1, #2 and #4 (**Figure 8**), the section 45+20mE with hole 5 (**Figure 9**) and the section 44+90mE with hole #6 (**Figure 10**)

During the campaign, samples were taken in all 6 holes for geochemistry study. Samples were analysed to provide whole rock assays for every geological units. During the summer and fall of 2007, Tim Barret of Ore Systems Consulting conducted a lithogeochemical study on those units. As well as collecting a considerable amount of his own samples, Barret also looked at the core from a selection of Matamec's 2006 and 2007 holes, as well as some of Pentland's 1999 holes. The goal of this study was to define the stratigraphic sequence present on the property, in particular as relate to the lithological contacts favored by known gold zones and their associated alteration trends. This study will be presented in an independent report available shortly, which study will also incorporates all historical geochemical data on the property.

## 9 - CONCLUSION AND RECOMMENDATION

Since the acquisition of this property by Matamec in March 2006, two drilling programs have been completed (summer of 2006 and winter of 2007). These two programs investigated two sectors of the Montclerg zone which was historically known to extend over a 2,600 metres length and to a depth of 150 metres.

The recent drilling programs identified two new and important features:

First: In the Main Zone area around section 49+00mE, new gold structures occur below 300 metres depth which contain semi-massive sulphide mineralization (mainly arsenopyrite with lesser quantities of pyrite and pyrrhotite and minor quantities of chalcopyrite and sphalerite); and

Second: In the West of the River area around section 45+50mE, weak gold mineralization with arsenopyrite has been found over significant intervals in a strongly altered felsic porphyry. The 2007 holes crosscut the same rock as the historic drilling and no value exceeding 6 g/t was encountered.

In the beginning of 2006 when Matamec optioned the property, the main goal was to test the extension at depth of all known mineralization in the Montclerg zone. Of the 14 holes drilled in this two campaigns though, only 4 were longer than 300 meters.

Before the beginning the next drilling program (designed to test the lateral and vertical extensions of these two discoveries), the lithogeochemical study will be completed and will hopefully yield an improved metallogenical model as well as help in the selection of targets for the next phase of drilling. But we do have to keep in mind that the main drilling objective was, and remains, to find more and better mineralization at depth.

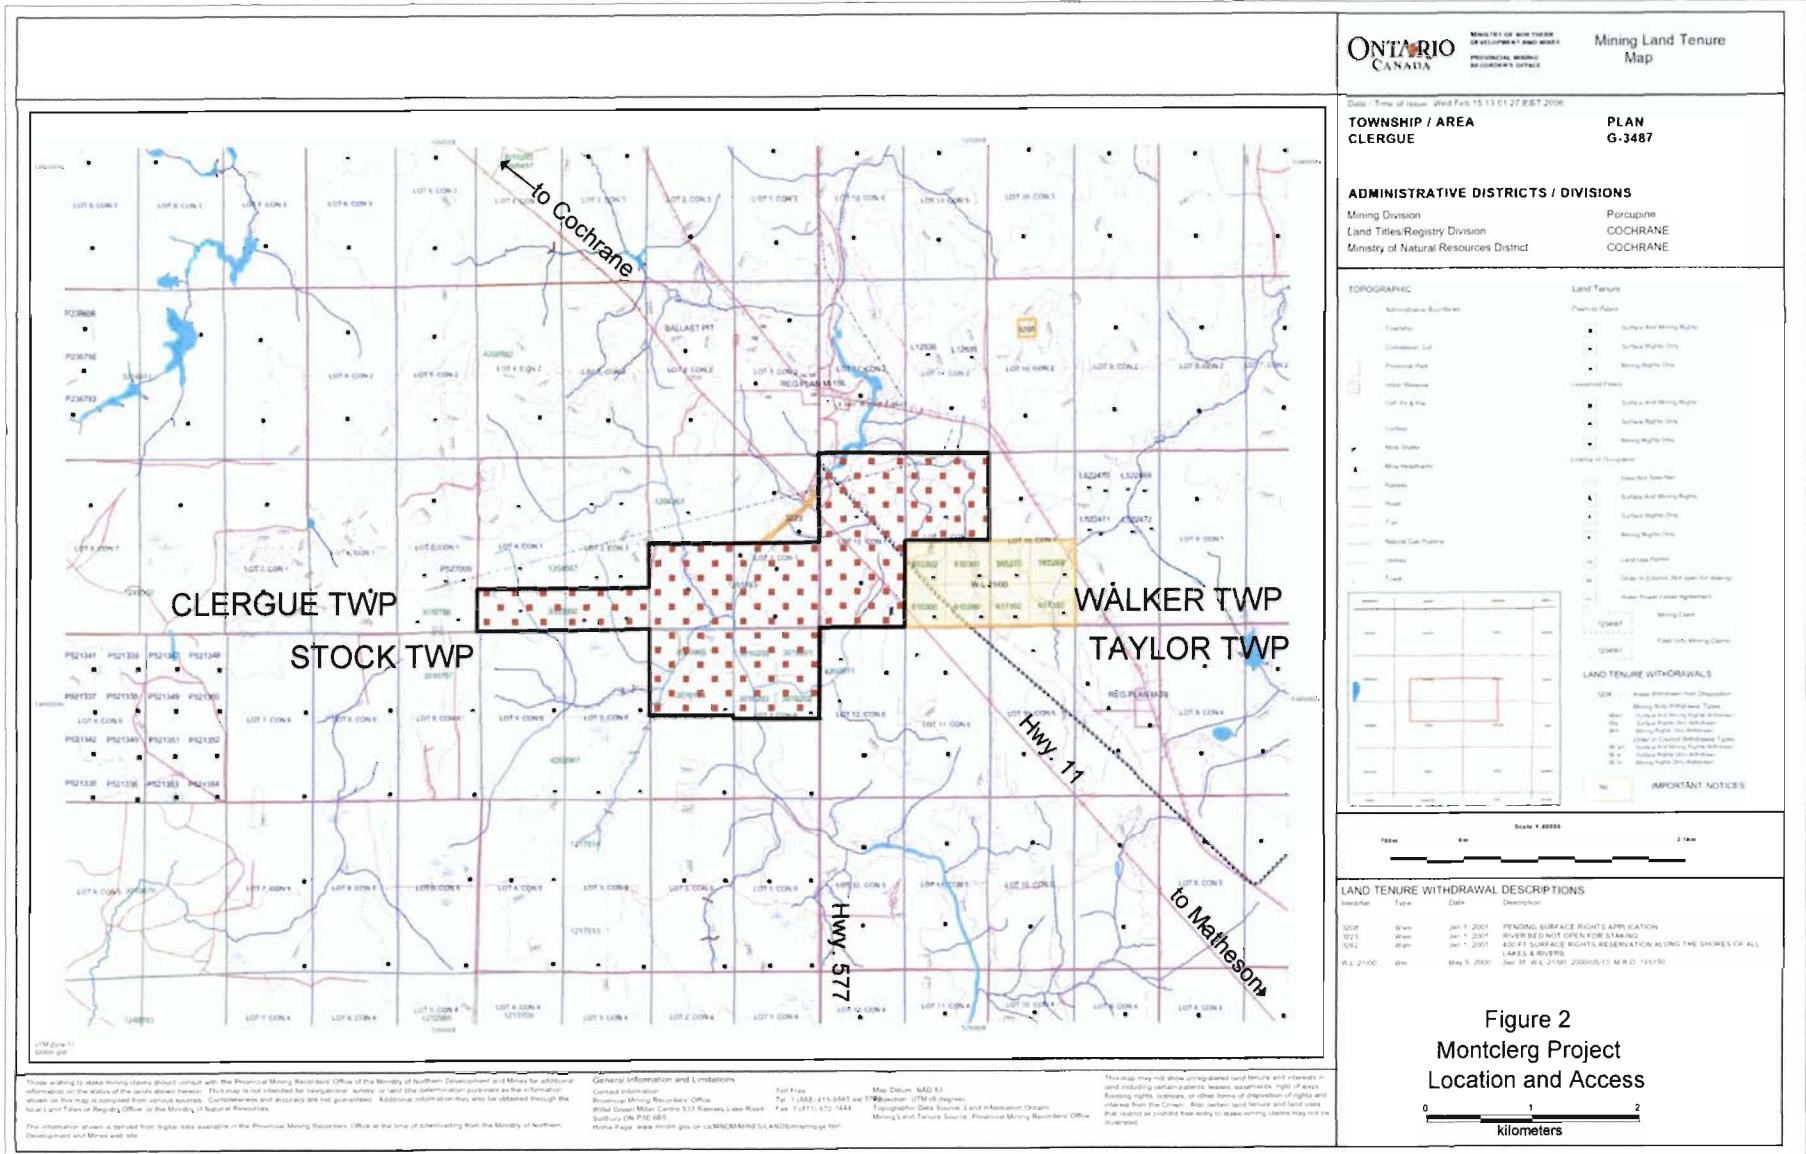

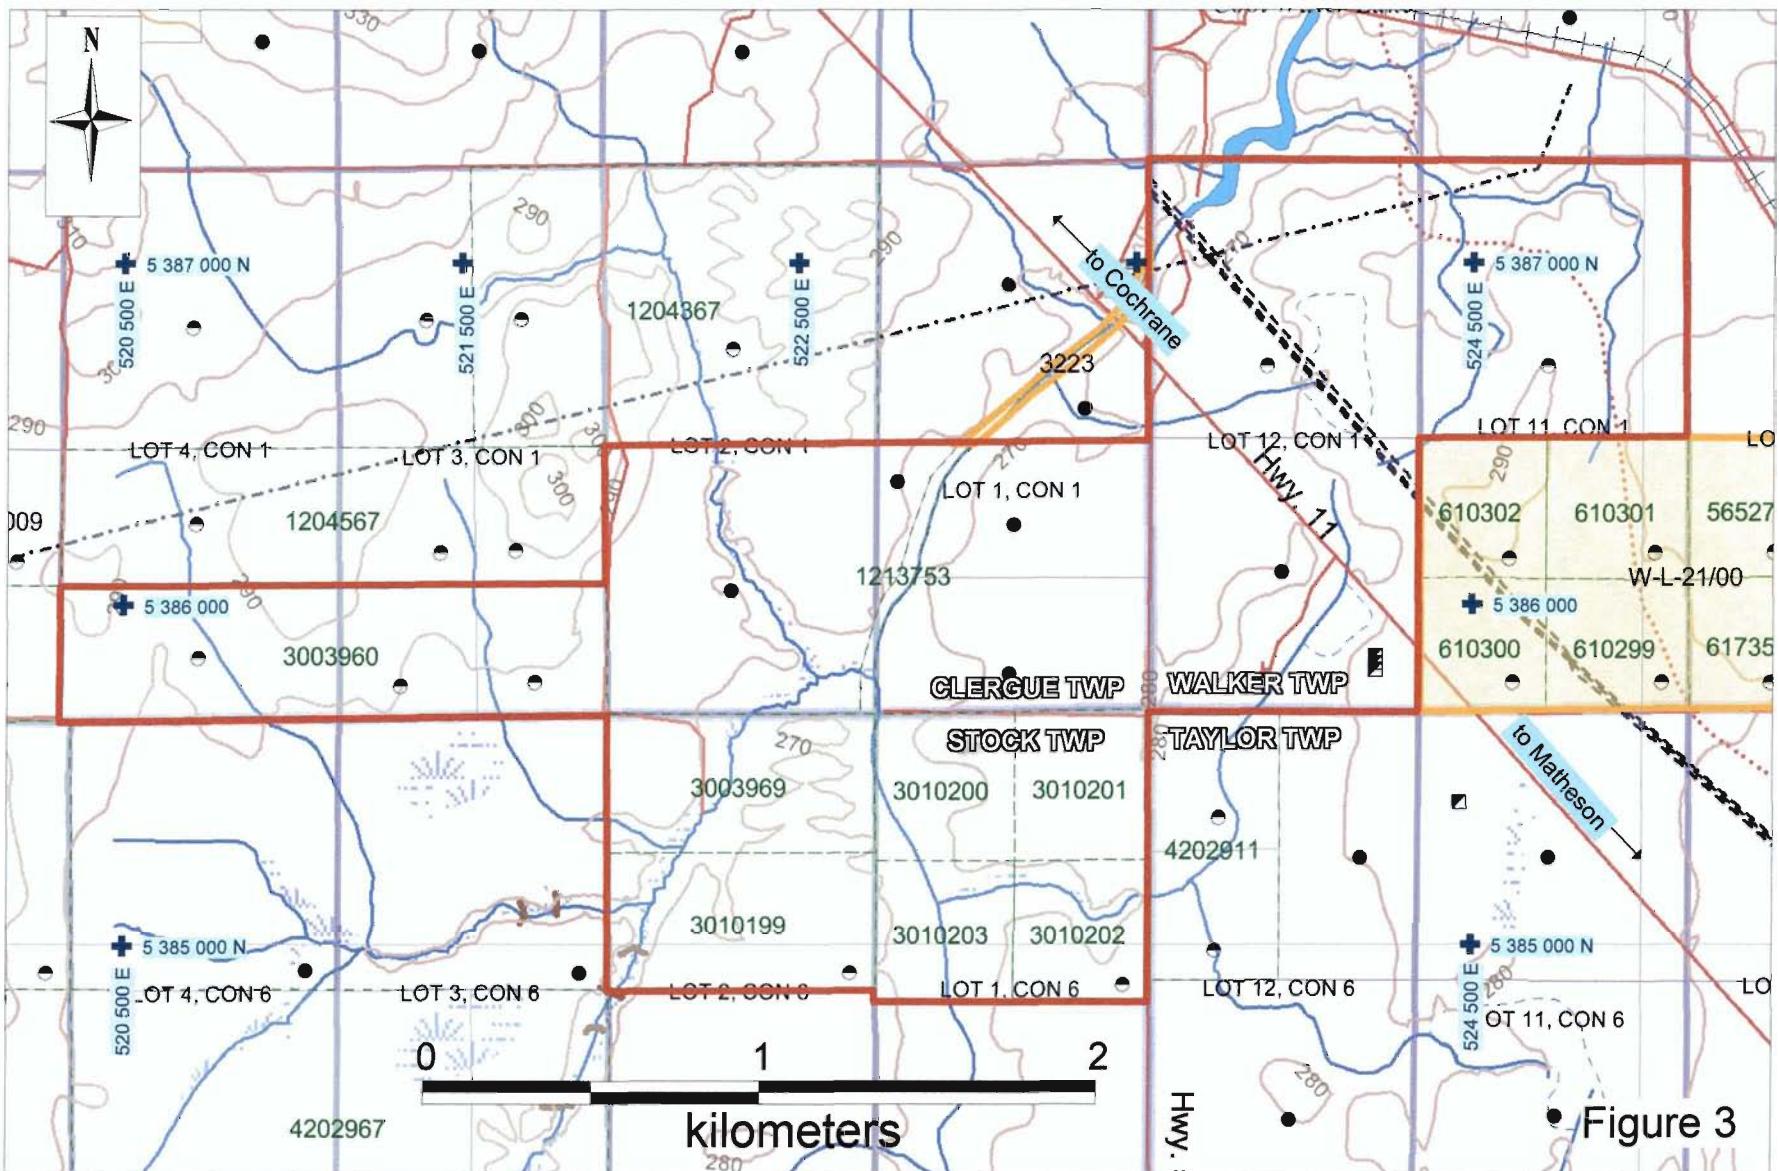

Aline Leclerc ogq 879

							Litho: 246.70 - 247.00 # E801550									
							sercite alteration									
							From 251.62 to 252.10 Dike silicified and mainly sericitized of aphanitic material									
							Contacts at 58° and 25° with CA									
							. From 256.5 to 257.45 Silicification cluster & streaks	D081189	256,40	257,45	1,05	0,013				
							Look more like chert than quartz, no sulphide									
							From 257.45 to 259.10. Unit becomming more and more silicicous toward the end of the hole									
							Look like more cherty material at the end from 258,80 to 259,10									
							Analyse litho: 258.80 - 259.10 #E801551									
							Chert and/or silicification									
							From 259.10 to 259.93 Fragmental unit: fragments from mm to cm nature more acidic									
							A few black argilite fragments more cm									
							Contact at 259.10 following a fracture at 75° and the contact at 259,93 parallel to the foliation at 25° with CA									
							These two last units look like bed of volcanoclastite									
							From 259.93 to 264.90 silicified and sericitized unit with Fd phenocrist									
							From 261.20 to 264.10 re-grind core lost 1.50 metres.									
							. Contact	D081190	264,40	265,25	0,85	0,010				
							. 3-4 % sulphide. Mainly pyrite	D081191	265,25	266,00	0,75	0,009
