1.0 Summary

This report summarizes the 2011 diamond drilling program completed on Zenyatta Venture's Albany Project, **Block 4F**. The 4F claim block is located in northwestern Ontario, Canada within the NTS blocks 42F/15,16 and 42K/01,02 (see Figures 1a, 1b). Block 4F is part of Zenyatta's group of 28 claim blocks. The claim blocks are all located within in the Porcupine Mining District of Ontario, and are presently held 25% by Zenyatta and 75% by Cliffs Natural Resources Exploration Canada Inc (CNRECI).

Zenyatta is conducting staged exploration programs targeting nickel (Ni), copper (Cu), platinum group metals (PGMs) and REE's (rare earth elements) on the highly prospective 'new frontier' properties containing a vast underexplored area referred to as the Albany Project or "Arc of Fire" in the James Bay Lowlands. The area has been largely ignored in the past because of younger Phanerozoic (460-360 Ma) cover rocks that overlie the prospective Archean rocks. Recent advances in airborne electromagnetic (EM) technology have allowed for deeper penetration/resolution through the iron deficient shallow marine sediments. In March, 2010, Zenyatta contracted Geotech Ltd. to conduct an airborne magnetic and electromagnetic geophysical survey on the Albany Project claim blocks. Results of the airborne survey outlined several magnetic and electromagnetic geophysical targets that prompted Zenyatta's 2011 drilling program.

Ontario Geological Survey (OGS) geologist, Greg Stott, interpreted the region's Precambrian geology (Stott et. al., 2007) based on government airborne geophysical surveys and limited geological data from exploratory diamond drilling conducted in the area. Stott grouped the Precambrian basement rocks into separate terranes and basins. **Claim Block 4F** overlies the boundary between the "Quetico Basins" in the south and the "Marmion Terrane" rocks in the north of the claim block. Known mineral occurrences (from historic drilling) within the Albany 28 claim groups include magnetite, pyrrhotite, chalcopyrite, pyrite, sphalerite, and niobium.

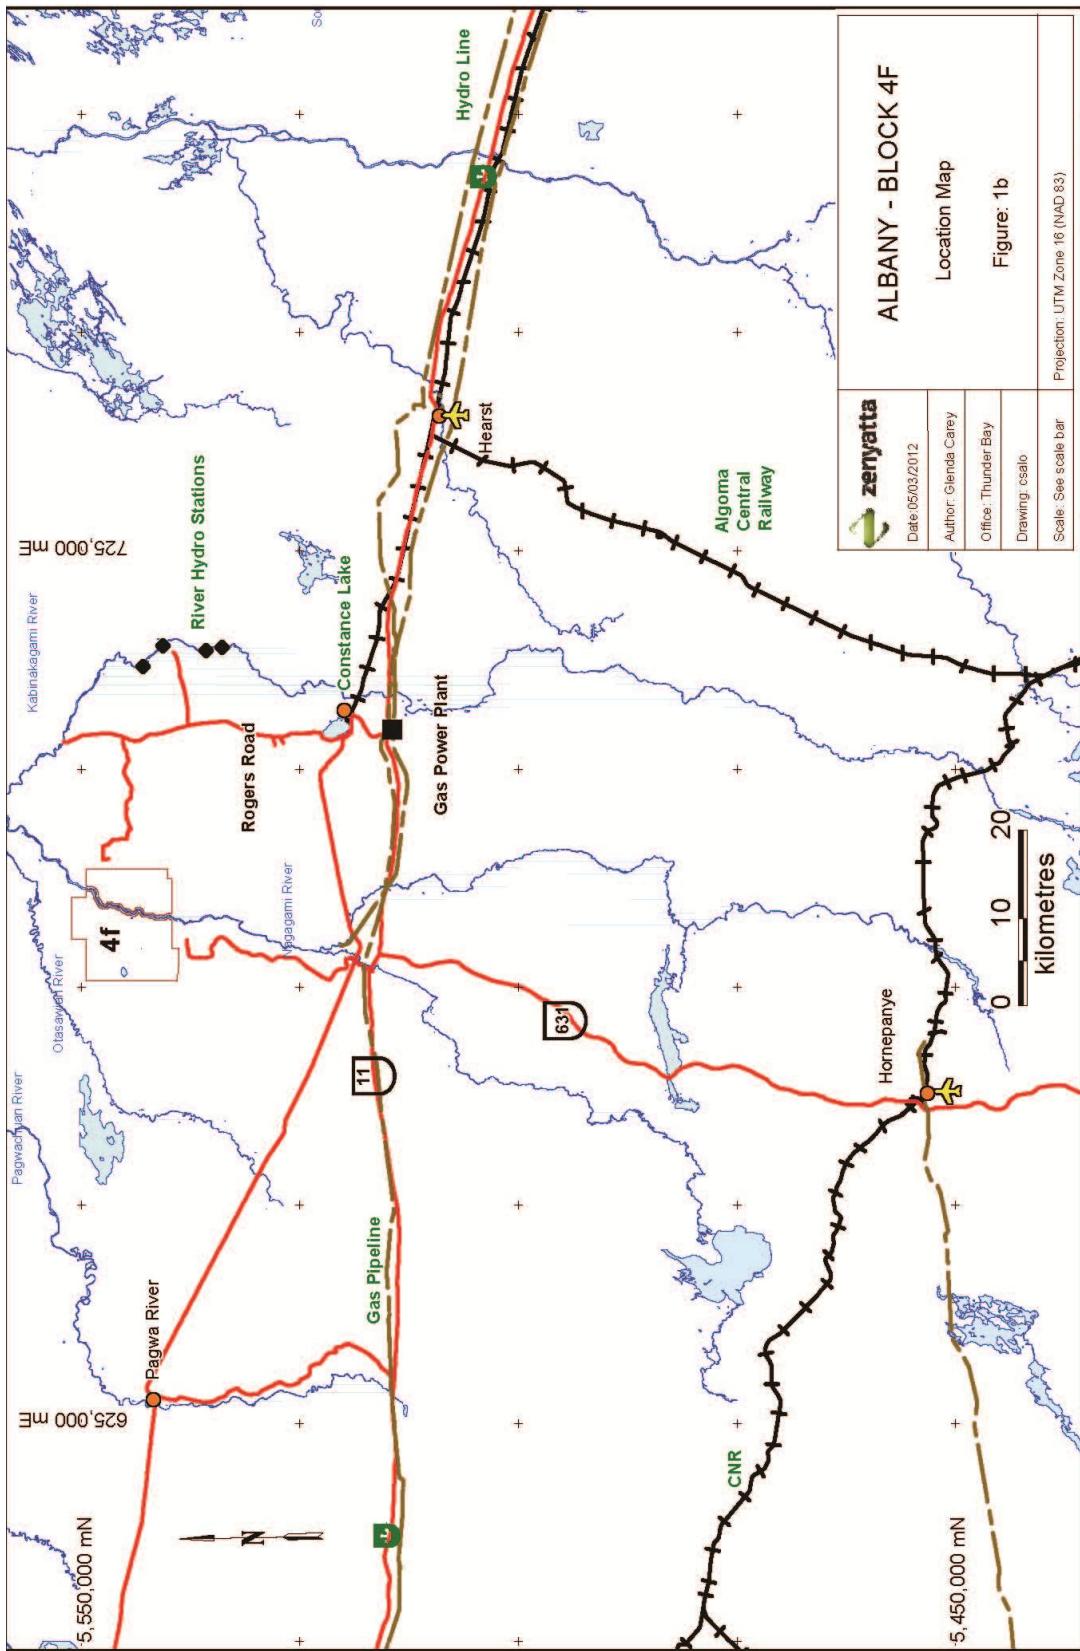

Previous exploration in Block 4F has been limited. Documented assessment work from the Ministry of Northern Development and Mines (MNDM) includes: ground geophysical surveys by Nagagami River Prospecting in 1959; airborne and ground magnetometer surveys, and diamond drilling in the 1960s by Algoma Ore Properties; and in 1978, diamond drilling by Shell Canada Limited.

In the fall of 2011, Zenyatta drilled one hole, DDH **Z11-4F1** in Block 4F, on a Geotech target, a VTEM conductor with a strong EM response on eight flight lines. The conductor was intersected by this first drill hole and was explained by the presence of several **graphitic brecciated** zones interlayered with gneiss, intrusives and dykes. Drill hole Z11-4F1 was drilled to a depth of 543m and a total of 338 core samples were collected and sent for geochemical analyses to ALS Chemex in Vancouver, British Columbia.

In 2011, graphite has increased in value due to a higher number of technical demands for carbon (C) and reduced exports from China. Therefore, in 2012, Zenyatta is planning further exploration drilling on the graphitic breccia zones to evaluate the grade and extent of graphite mineralization.

2.0 Introduction

Zenyatta Ventures Limited is conducting staged exploration programs on its 28 Albany Project claim blocks. The Albany Project claim blocks are all located in the James Bay Lowlands Region of Northern Ontario (*see Figure 2*). Several targets were outlined in the Albany claim blocks based on the results of the 2010 Geotech Airborne Magnetic and Electromagnetic Survey. In **Block 4F**, the airborne survey detected a strong electromagnetic response located west of the Nagagami River and oriented east-west on eight flight lines (approx. 1.5 kms). This drill target was interpreted as a thick vertical conductor, dipping to the south with no magnetic response.

In the winter of 2011, Zenyatta initiated a reconnaissance drilling exploration program which included Phase 1 drilling on four of the claim blocks: 1C, 2C, 4A, and 4B. During the fall of the same year, Zenyatta continued Phase 1 drilling on Albany Blocks 4A, **4F**, 2I, 2B, and 1D.

To this date, exploration work carried out by Zenyatta on Albany **Block 4F** includes the airborne geophysical survey and one diamond drill hole, **Z11-4F1**, targeting the strong conductor. Drilling commenced on September 11th, 2011 and ended on September 24th, 2011. Drilling intersected several zones of *graphitic brecciated granitic to syenitic gneiss* alternating with layers of gneiss, lamprophyre and trachyte.

Figure 2: Albany Project – 28 Claim Blocks

3.0 Property Description

The Albany Project claim group **Block 4F** is located north of Lake Superior and west of James Bay in northwestern Ontario, Canada. Most of the Block 4F claims are located in the township of Pitopiko River, with the westernmost claims located in the Feagan Lake Township. The Block 4F claims are situated within NTS blocks 42K/01,02 and 42F/15,16 and most were staked during the months of March and May of 2010. Block 4F (*see Figure #3*) has a total of **61 claims, 844 claim units**, and make up **13,504 hectares**. The yearly work required costs to keep the total claims in good standing amounts to **\$337, 600**.

Block 4F is part of a large group of claims (*see Figure #2*) that make up the Albany Project and include 28 groups of claims totaling 495 claims, 7757 claim units, and 124,112 hectares. The Albany claims are 25% owned by Zenyatta and 75% owned by CNRECI. The majority of the entire Albany Project claims were staked during the late summer and fall of 2009, followed by additional staking in the winter and spring of 2010. The Albany **Block 4F** claims were staked during the winter and spring of 2010.

The Block 4F property is not subject to any known environmental issues, and no abandoned mine workings or tailings are present on the property. The surface rights are owned by the crown. The forest on the east side of the Nagagami River has been locally harvested. Table #1, presented below, lists the entire Block 4F claims and expiry dates.

4.0 Location, Access and Topography

Zenyatta's Albany Project blocks, including Block 4F, are situated within the Porcupine Mining District of northern Ontario, Canada. The claims are located approximately 50 kilometres northwest of Highway 11 and the small town of Hearst, population of 5825 (*see Figure 1b*). Most of the Block 4F claims are located in the Township of Pitopiko River, with the westernmost claims in the Feagan Lake Township. The claim group is located within NTS blocks 42K/01,02 and 42F/15,16. The central area of the claim block is located at UTMs: 682,400 E and 5,544,514 N, Zone 16, NAD 83.

Access to most of the 4F claim block can be gained using helicopter, but boat or canoe access can be used along the Nagagami River in the central area of the claim block. Old forestry logging roads reach the south-east boundary of the claim block, leading to several old quad trails through previously harvested forests just east of the Nagagami River. The small town of Hearst, located approximately 50 kilometres to the southeast of Block 4F, has many facilities to keep an exploration camp well supplied. These include hotels, restaurants, a hospital, hardware stores, gas stations, mining supply store, and an airport. Float plane and helicopter services are available in Hearst.

The claims are situated within the Hudson Bay-James Bay Lowlands area where the topography is essentially flat, low-lying and swampy. Overburden is thick, approximately 35 metres in the Block 4F area with little or no outcrop exposure. There are many creeks flowing between peat bogs throughout the area. The Nagagami River flows north through the property with several meandering tributaries flowing in from the east and west. The Pitopiko River flows into the west side of the Nagagami. Vegetation is dominated by wetlands with some areas of spruce and alder trees, and cedar swamps. Spruce and alder trees are also abundant along the banks of the Nagagami River and other smaller rivers.

The Albany claims are situated in northern Ontario where there are various climates and weather extremes. Most of the region has a continental climate with warm to hot summers (June, July and August; 25 to 35 degrees Celsius) and cold winters (December to March, 10 to -30 degrees Celsius). Spring and autumn tend to be short seasons and have some of the weather of winter and summer. Generally, precipitation ranges from 600 millimeters to around 900 millimeters.

Surface exploration work can be carried out during the months of May to November, possibly later if there is no snow accumulation. Airborne or ground geophysical surveys and diamond drill programs can be conducted year round.

5.0 Historical Work

Zenyatta's Albany Project claim groups total 28 blocks and cover large amounts of ground. The ground was selected based on geophysical information from OGS airborne magnetic maps, the geological interpretation (Greg Stott, 2007-2008) of these maps, and additional geological and geophysical data from historical exploration reports provided by MNDM. Historical exploration work has been limited in this area of the James Bay Lowlands and mostly consists of geophysical surveys and diamond drill projects. The following is a brief summary of the reported historical exploration work carried out in the area of **Albany Project Block 4F**:

1959: A ground magnetic and electromagnetic survey was initiated on claims held by **Nagagami River Prospecting Syndicate** in the Feagan Lake/Pitopiko River Townships area. The geophysical survey was carried out by Koulomzine and Brossard Limited but was not fully completed because of an early spring breakup. Results of the survey showed three magnetic anomalies defining basement geology contacts and several vertical-loop electromagnetic conductors. It was concluded that "*the general lenticular nature of the conductors and their occurrence in the vicinity of a diabase dyke, may suggest the presence of sulphide lenses that could contain base metals; one anomaly (magnetic & EM) could be due to some disseminated mineralization*" (Koulomzine, 1959). They recommended drilling four holes to investigate the EM anomalies but there is no record that these holes were ever drilled.

1961: **Algoma Ore Properties Limited** flew an aeromagnetic survey in the Nagagami River and Pitopiko Townships area. The survey outlined a horseshoe-shaped anomaly which was confirmed on the ground in the same year. This led to further exploration in 1963.

1963: **Algoma Ore Properties Limited** flew an airborne magnetometer survey in the Nagagami River area, located forty miles north-west of Hearst, Ontario. The survey was flown by Hunting Survey Corporation. The survey results indicated two large low intensity circular shaped anomalies (Anomalies #1 and #2), underlying the Paleozoic limestones. Interpretation of the anomalies inferred that they were caused by a complex syenitic to gabbroic intrusion. It was reported that Anomaly #1 could be associated with a basic intrusive, hosting magnetite, and thought to be mildly interesting for iron ore, niobium, and sulphides. Anomaly #2 was interpreted to be associated with an alkaline and carbonatite complex and could contain columbium and other rare earth elements (REEs). Algoma recommended follow-up work to include a ground magnetometer survey over the anomalies and a diamond drill program (Venn, V.R., 1964).

1964 - 1967: **Algoma Ore Properties Limited** continued exploration in the Nagagami River area. Ground work involved grid cutting followed by a ground magnetometer survey and claim staking. Algoma drilled nine holes (located in **claim blocks 4E and 4F**) for a total of 4,868 feet. Holes 1-64 to 7-64 were drilled in Block 4E. Two holes were drilled in Anomaly #2 (DDH's: 8-64 and 9-64), reported to be located near the northern boundary of Block 4F. Erratic sampling was done on the core, along with petrographic studies. The core was tested with scintillometer, and samples were taken where radioactive responses occurred; assay results indicated columbium (Cb_2O_5) content to be

.02% to .04%. Drilling on Anomaly #2 intersected coarse syenite rock with 3-5% magnetite. It was concluded that the ground magnetometer survey and the diamond drilling verified the airborne survey fairly well, and although drilling did not intersect any ore minerals, the structure was still geologically interesting. Algoma reported that minerals of economic potential could possibly be associated with other parts of the structure and they recommended that the property be referred to other companies interested in intrusive structures, while retaining 10% interest in the property (Venn, V.R., 1964).

1978: *Shell Canada Explorations Limited* initiated a diamond drill program in the area based on results of an airborne geophysical survey. Drill logs for 22 drill holes were available from MNDM, but no report was submitted with the logs. One hole, **DDH 7609-78-1** was drilled within Block 4F in the Pitopiko River Township. The remaining reported Shell holes were drilled to the south and west of Block 4F.

1988: *Sage, R.P.*: authored report Study #43 on the Geology of Carbonatite, Nagagami River Alkalic Rock Complex, Ontario Geological Survey

1999: The *Ontario Geological Survey* (OGS) released aeromagnetic geophysical maps for the Hudson Bay and James Bay Lowlands areas, *Geophysical Data Set 1036*. (see *Figure 5 for Block 4F area*)

2008: The *Ontario Geological Survey* (OGS) Precambrian Geology Map P.3599 was published: *Hudson Bay and James Bay Lowlands Region Interpreted from Aeromagnetic Data*, G.M. Stott, 2007–2008. (see *Figure 6 for Block 4F area*)

6.0 Geological Setting

6.1 Regional Geology

The following are excerpts from Stott's (2007-2008) "Marginal Notes", Map P3599, describing the interpreted Precambrian Geology of the Hudson Bay and James Bay Lowlands Region:

The relatively flat-lying Hudson Bay and James Bay Lowlands, consist mostly of carbonates of Paleozoic to Mesozoic age. These sediments cover a significant portion of the Precambrian rocks of Northern Ontario and therefore, have impeded the understanding of the Precambrian geology and the tectonic framework across this region of Ontario. The regions Precambrian geology is based mainly on available reprocessed aeromagnetic data and limited drill hole information. The results provide a general framework of interpreted supracrustal belts, plutonic subdivisions, major faults and Proterozoic mafic dikes. (see Figure 4)

In the James Bay Lowland area, the most significant feature is the aeromagnetic expression of the Uchi domain greenstone belts, along the southern flank of the Sachigo superterrane trending northeast under the James Bay Lowland and wrapping around the eastern end of the Island Lake domain, a portion of the Sachigo superterrane. This greenstone trend merges with the Oxford–Stull domain near the western margin of the James Bay Lowland just east of the McFaulds Lake massive sulphide deposits. This combined array of Neoarchean greenstone belts continues east, narrowing under the James Bay Lowland, towards the Eastmain greenstone–granite domain in Quebec.

The Northern Superior superterrane forms a 1000 km long band of distinctively strong magnetic intensity. A marked magnetic discontinuity can be traced eastward roughly midway under the Hudson Bay Lowland between a region of high magnetic relief and complexity that characterizes the Northern Superior superterrane to the south and a region of relatively flat magnetic character that more closely resembles the magnetic signature of the Trans-Hudson Orogen. However, a significant portion of the interpreted Trans-Hudson Orogen resembles an extension of the Northern Superior superterrane and is interpreted as an area of Archean crust that was overprinted by the Trans-Hudson Orogen. The Sutton Inliers have been reinterpreted by comparing the aeromagnetic data and the outcrops mapped by Bostock. Current regional geology maps of Ontario portray the Sutton Inlier as a single large mass. This new interpretation recognizes a set of ridges forming several crescent-shaped inliers that dip shallowly northward. They appear to be discontinuously related to similar narrow, folded magnetic anomalies within the Trans-Hudson Orogen under the Paleozoic rocks closer to the Hudson Bay coast.

Two sialic terranes, the Northern Superior superterrane and the Sachigo superterrane, each have complex, but distinct, episodic magmatic and tectonic histories. The Northern Superior superterrane contains remnants of a record from Paleo- to Neoarchean and geophysically and isotopically can be linked to the Assean gneisses in Manitoba. The Sachigo superterrane with magmatic episodes from Meso- to Neoarchean age, encompasses a core terrane, the North Caribou terrane (NCT), and linear granite–greenstone domains on its south and north flanks that record an outward growth through the Neoarchean.

The Island Lake domain is largely plutonic with some Mesoarchean to Neoarchean volcanic belts with geophysical characteristics that show some relationship to the belts within the North Caribou Terrane. The boundaries of the Island Lake domain are probably the least understood and remain the most contentious. At the northern margin of the Sachigo superterrane, the narrower, ribbon-like Oxford–Stull domain (OSD) stretches from Manitoba to the James Bay Lowland (see Figure 4). The OSD displays some evidence of Mesoarchean mid-ocean ridge basalt (MORB)-like sequences concurrent with continental magmatic growth within Northern Superior superterrane and NCT margins to the north and south, respectively. At the edge of the James Bay Lowland in Ontario, the Oxford-Stull Domain includes a calc-alkaline metavolcanic sequence containing volcanic-hosted massive sulphide deposits at McFaulds Lake.

The Uchi domain forms the southern part of the North Caribou terrane within the Uchi Subprovince. The Uchi domain was constructed largely by autochthonous, episodic additions of volcanic assemblages and accompanying plutons during the Neoarchean era (Stott and Corfu 1991). The eastern extent of the Uchi domain underlies the James Bay Lowland where, from high-resolution aeromagnetic images, it appears to merge with the OSD. The resulting merged greenstone–granite domain continues eastward under the James Bay Lowland on strike with the Eastmain greenstone–granite domain of Quebec.

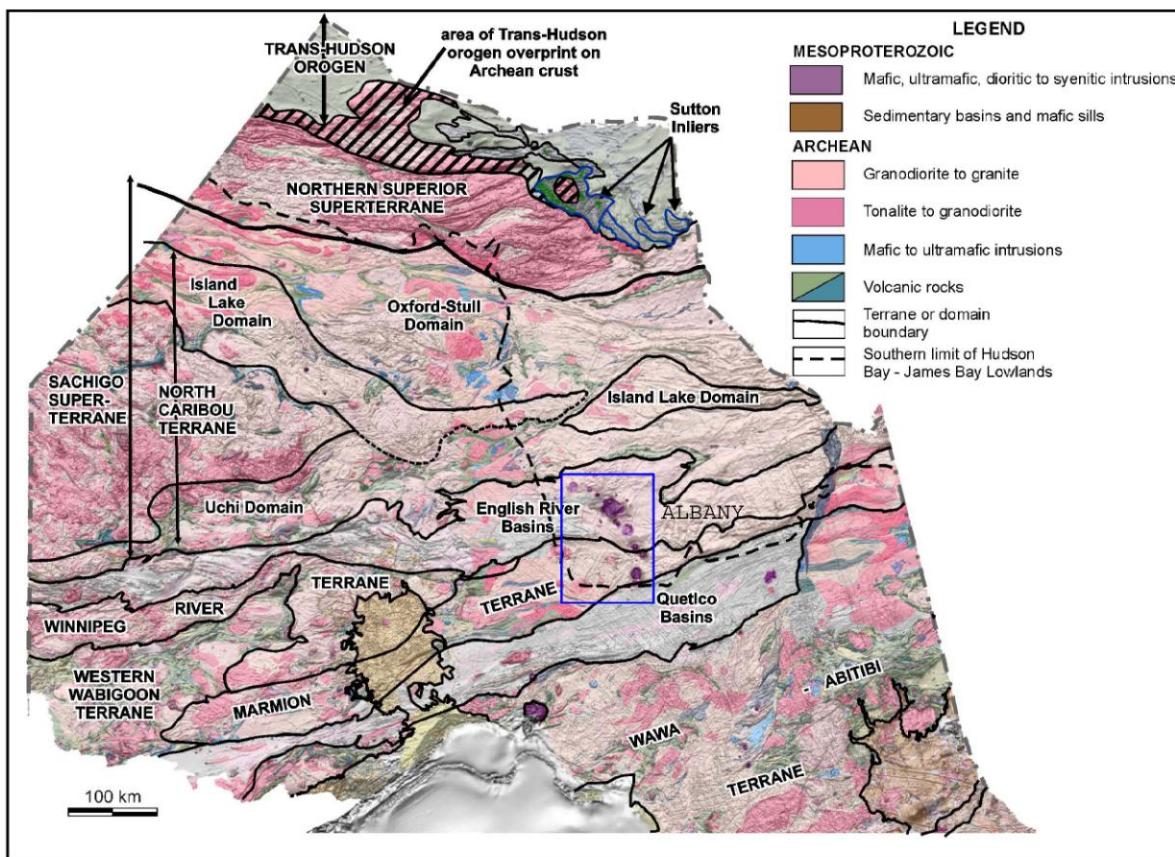

Figure 4. Regional tectonic subdivisions of northern Ontario (after Stott et al. 2007).

According to Stott's (2007) regional tectonic subdivisions map, Zenyatta's **Block 4F** covers parts of the **Marmion Terrane** and the **Quetico Basins** of the Superior Province of the Canadian Shield:

The Quetico Subprovince: *The Quetico Subprovince is an east-northeast trending, 10 to 100 km wide by 1200 km long belt of variably metamorphosed and deformed clastic metasedimentary rocks and granitoids located in the west-central part of the Superior Province. The metamorphic grade varies from greenschist to amphibolite to local granulite facies. The metasedimentary rocks were deposited before 2696 Ma. The Quetico intrusions near Atikokan are typically small (<1km²) and form spills, plugs, and small stocks composed of a variety of lithologies, mainly wehrlites, clinopyroxenites, hornblendites, monzodiorites, syenites, foidites and silicocarbonatites. They are locally enriched in Ni-Cu and PGEs (Vaillancourt, C., et. al.).*

Marmion Terrane/Subprovince: *This terrane consists predominately of metamorphosed felsic intrusive rocks. The 3.0 to 2.7 billion year old rocks are interpreted as an assemblage of continental fragments. These rocks were once also interpreted as part of the Western Wabigoon and Winnipeg River terranes (MNDM, Government of Ontario).*

6.2 Property Geology

The Albany Project Block 4F area is covered by a thick layer of overburden, approximately 31 metres in Z11-4F1, and therefore no historical geological mapping projects were reported for the area. Underlying the overburden are the James Bay Lowlands flat-lying Paleozoic rocks, and in DDH Z11-4F1, drilling intersected the Precambrian basement rocks at 48 metres. According to Stott's Precambrian Geology Map (*see Figure 6*), the southern section of 4F claim block is underlain with mostly paragneiss and migmatite metasedimentary rocks, and mafic with related intrusive rocks of the Quetico Subprovince. The northern section of Block 4F is underlain with metamorphosed tonalite to granodiorite, foliated to gneissic with minor supracrustal inclusions of the Marmion Terrane/Subprovince. Both subprovinces have been intruded with a younger alkalic intrusive suite made up of alkalic syenite, ijolite, associated mafic and ultramafic rocks and carbonatite (Stott, 2007-2008).

Documented assessment work from MNDM reported diamond drilling in the 1960s by Algoma Ore Properties; and in 1978, diamond drilling by Shell Canada Limited. Precambrian rock types reportedly observed in these historical drill holes include mostly syenite and granite, minor pegmatitic intervals and an aplite dyke. In Zenyatta's Z11-4F1 drillhole, intersected basement rocks were identified as alternating layers of nepheline syenite, graphitic granitic gneiss, lamprophyre, granitic gneiss, syenite, trachyte and mafic dykes.

In 1988, OGS geologist R. Sage reported (Study #43) on the Nagagami Alkallic Rock Complex, which underlies the northern section of Block 4F:

The Nagagami River Alkallic Rock Complex lies beneath swamp, muskeg, glacial till, and Paleozoic rocks of the James Bay Lowlands. The complex is unexposed and all descriptive data concerning this complex came from the limited number of samples

available from diamond drilling. Aeromagnetic data indicate that the complex consists of two ring-shaped subcomplexes. The aeromagnetic pattern of the southern subcomplex cuts that of the northern subcomplex, suggesting that the southern subcomplex is younger. Linear northwest-trending aeromagnetic patterns attributed to diabase dikes do not cross the aeromagnetic pattern of the alkali rock complex, suggesting that these dikes are cut by the alkalic rocks and thus are older. This observation, combined with the fresh unmetamorphosed nature of the rock, suggests to the author that the complex is likely of Late Precambrian age, equivalent to the dominant period of alkali magmatism in Ontario. Regional structures that control the emplacement of the subcomplexes have not been clearly identified but the complex lies on trend with the extension of the northeast-striking Gravel River Fault.

The dominant rock type is an amphibole-pyroxene syenite which varies from fine to coarse grained, and locally displays a trachytoidal texture. A coarse-grained nepheline-bearing phase appears restricted to the southern subcomplex. A very coarse-grained pegmatitic phase and a minor granite phase have also been identified. Petrographically, the Nagagami River Alkalic Rock Complex has strong similarities to the pyroxene-bearing syenites of the Port Coldwell Alkalic Rock Complex.

The intrusion underwent unsuccessful testing for iron and niobium in 1964 by the Algoma Ore Properties Division of Algoma Steel Corporation. Future exploration of the complex should be directed towards the type of mineralization found in equivalent syenitic rocks of the Port Coldwell Alkalic Rock Complex (Sage, R.P., 1988).

Mineralization

Located near the northeast corner of Block 4F, the following mineral occurrences are Ontario Geological Survey occurrences catalogued from historical reports:

DDH #8-64: UTM's 685792E, 5551132N, NAD 83, Zone 16 - trace amounts of REE's in drill hole - 0.04% columbium, 0.1% lanthanum, 0.02% neodymium, from Algoma drill hole 8-64

DDH #9-64: UTM's 685237E, 5550906N, NAD 83, Zone 16 - Niobium - a sample of amphibole pyroxene syenite assayed 0.3% Nb₂O₅ (MDI# 42K01SW00004) from Algoma drill hole #9-64

South of and adjacent to Zenyatta's Block 4F, the exploration company GTA Resources holds a large group of claims covering an east-west trending, approximately 300 foot wide iron (Fe) formation. The following are mineral occurrences located on the GTA claims that occur directly south of Albany Block 4F:

McGale Copper Prospect: UTMs: 682447E, 5537854N, NAD 83, Zone 16
According to MNDM mineral occurrence database, the McGale Copper occurrence is described as "having two main zones of sulphide mineralization: an exposure 25-30 foot wide on west bank of river at the rapids (20% to massive pyrite and pyrrhotite with minor

quartz as lenses and disseminations; very little copper mineralization in evidence, strongly magnetic) and an eight foot zone on the east shore of the river north of the rocky island and 50 foot south of the conglomerate consisting of fine-grained massive pyrite. Algoma personnel noted a few small quartz-chalco-pyrite veins a few inches wide in conglomerate to the north of the east bank exposure. Drilling to the west of the river intersected paragneiss, quartzite and conglomerates and zones of varying degrees of sulphide mineralization."

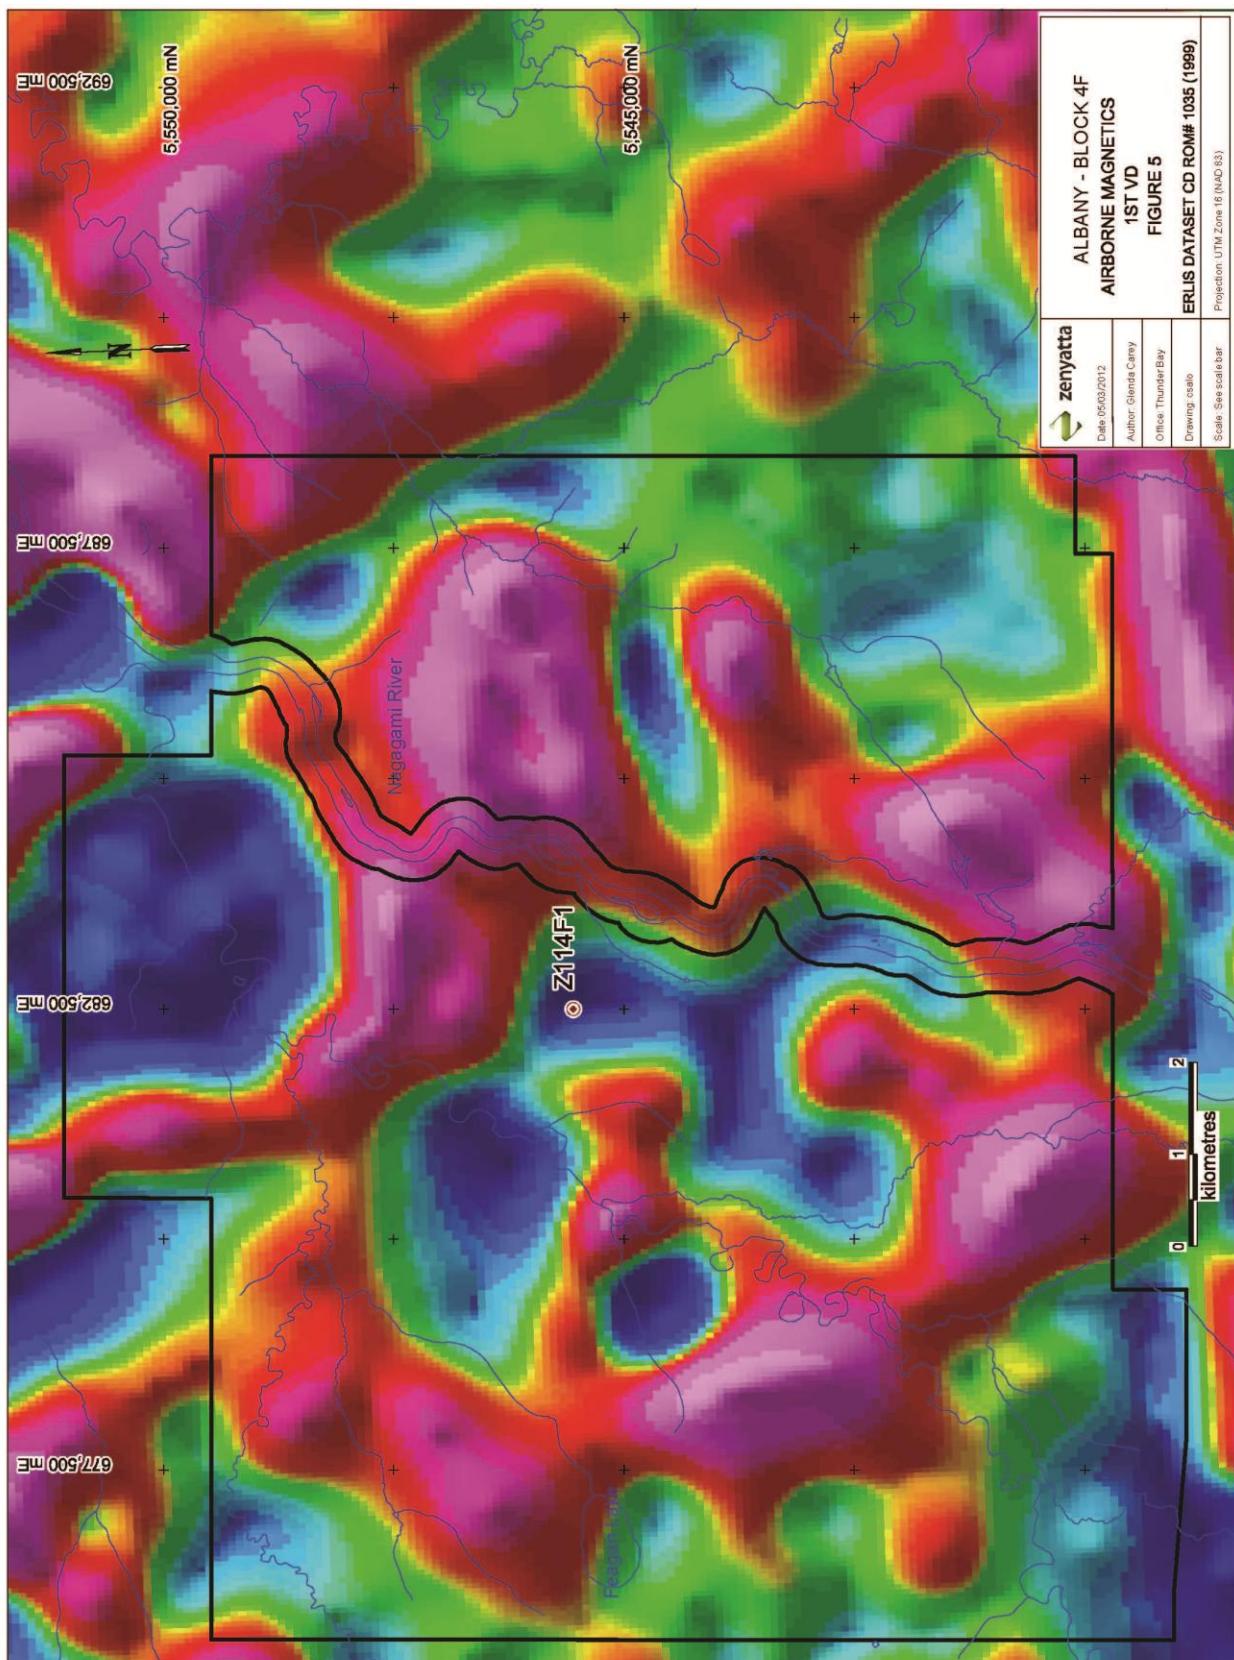

McKinnon DH 7-14-1 (1993): UTM斯 – 687397.8E, 5538729.2N, NAD 83, Zone 16 Au occurrence in mafic tuff; section is dark green, fine grained with anhedral garnets and minor biotite, blue grey quartz stringers. A sample of 1.3m of mafic tuff assayed 0.77g/t Au. The following metre assayed 0.39g/t Au.

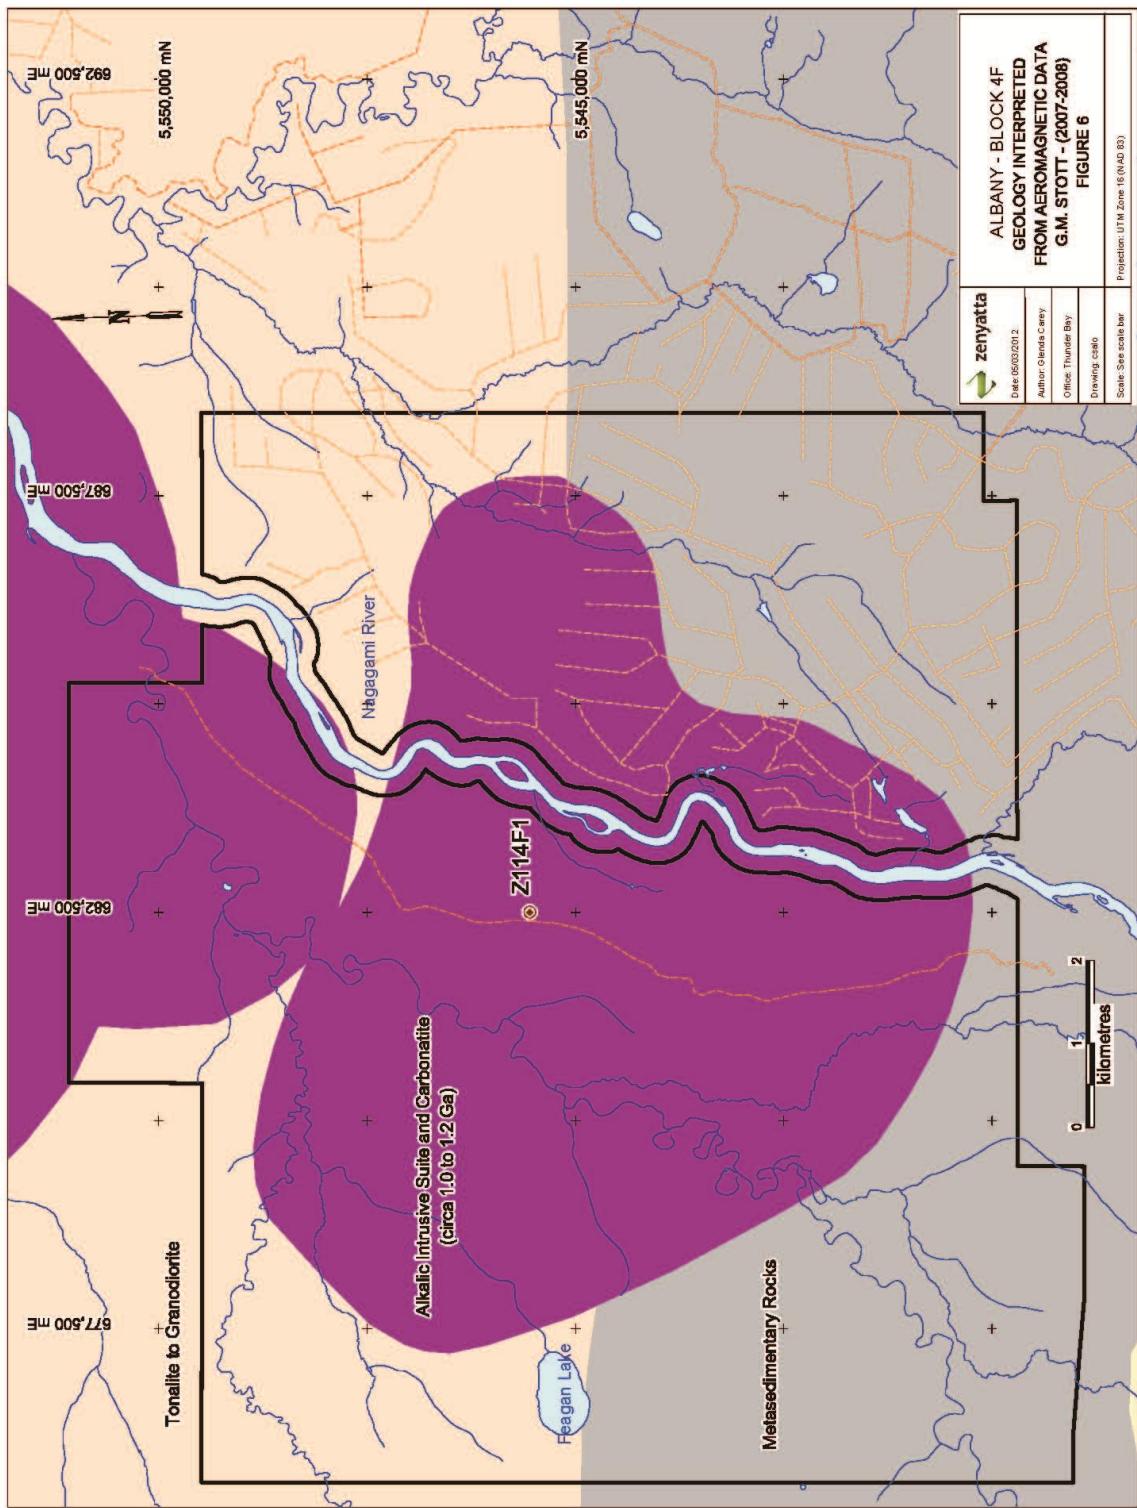

McKinnon DH 7-17-1 (1993) and Shell DH 7609-78-4(1978): Approximate UTM斯 – 685622.8E, 5538329N, NAD 83, Zone 16

In McKinnon hole 7-17-1 sampling of iron formation returned assays up to 3.33g/t Au; trace arsenopyrite and galena also noted in log. In Shell hole 7609-78-4, a 1.0 metre section of pyrrhotite rich iron formation (75.64-76.64m downhole) assayed 0.02 opt Au. Sampling of the Shell core in 1990, a 16 metre section of the pyrrhotite rich iron formation assayed up to 1277ppb Au. This was named the Auden Gold occurrence.

Algoma DH 10-64 (1964) and DH 11-64: approximate UTM斯 – 676017.9E, 5536878.9N, NAD 83, Zone 16

In DH 10-64, a 5 foot sample collected at 390-395ft, assayed 0.03 opt Au. In DH 11-64, sample at 240-245ft assayed 0.02 opt Au. The rock type was identified as an intermediate intrusive, synodiorite.

7.0 Deposit Models

7.1 *Mafic-Ultramafic Intrusion Hosted Cu-Ni-PGM*

Mafic-ultramafic intrusion hosted Cu-Ni-PGM deposits range in age from Archean to Tertiary (mainly Archean and Proterozoic in Ontario), are stratabound, and host copper, nickel and/or platinum-group sulphides. These deposits generally occur in two types of cratonic settings: (1) as complexes related to flood basalts in an intracontinental rift environment; and (2) as large strataform complexes either sheet-like or dike-like. Host rocks include (commonly layered) norite, gabbro, quartz diorite, pyroxenite, amphibolite, diabase, peridotite, anorthosite, dunite, troctolite and harzburgite.

The principle mineralogy includes pentlandite, chalcopyrite, pyrrhotite, cubanite, and millerite; other minerals may include pyrite, marcasite, valleriite, bornite, cobalt sulphides and sphalerite. Platinum group minerals may include sulphides, tellurides, arsenides, antimonides and alloys. Generally, the more mafic the composition the higher the Ni/Cu ratio. The texture and style of the mineralization is disseminated, net textured, sulphide matrix breccia and massive sulphides that occur as stratabound to stratiform, tabular layers or lenses. The ore minerals are commonly located at or near the base of the host intrusion and sulphide veins and disseminations usually occur in the footwall rocks. PGM rich horizons generally occur at a significant distance above the base of the intrusion.

A geophysical anomaly for massive sulphides should be produced by an airborne or ground electromagnetic survey (EM). Airborne and ground magnetic (mag) surveys may produce anomalies for pyrrhotite mineralization.

7.2 *Albany Project - Hydrothermal Graphite*

Deposit Type: A magmatic hydrothermal breccia related to the emplacement of a carbonatite intrusion. The emplacement is along the deep seated, 150km long ‘Arc shaped’ Proterozoic structure that may be related to the 1.1 billion year old mid-continent rifting. A similar deposit may be the vein graphite deposit of Sri Lanka (Ceylon Graphite Deposits), which has been interpreted as being derived from hydrothermal fluids. The origin of the graphite is proposed to be the direct consequence of granulite facies metamorphism in the presence of a CO₂ rich fluid. This CO₂ rich fluid could promote hydraulic fracturing (brecciation) and precipitation of vein graphite (C). Graphite veins are unique and quite rare, and only a few of them are described in the geologic literature. The Bogala Mine, a Ceylon graphite deposit, has been in production since 1847. It is a high grade, narrow vein (20cm), underground mine. Ceylon graphite still enjoys a great demand due to its unusually high purity and unique physical properties.

8.0 2011 Diamond Drill Program

In 2011, Zenyatta Ventures completed Phase 1 drilling on a number of claim blocks, collectively named the Albany Project. The **Phase 1** drill program began in February of 2011 for the Albany Project and was completed on 17 December 2011. From the 11th to the 24th of September, DDH **Z11-4F1** was drilled on claim Block 4F and totaled 543 metres. To date, this was the only Zenyatta hole drilled on Block 4F. The hole was spotted using Garmin GPSmap 76S, with an accuracy of 3 to 5 metres. Core logging was completed near the claim site using a laptop computer and the Excel spreadsheet program.

Drill hole Z11-4F1 was designed to test a string of strong electromagnetic conductors. The location, azimuth, dip and length data are listed in Table #3 below, and shown on the drillhole location map (Map #1). Also included with this report is a drill section (Map #2) showing DDH Z11-4F1 in plan view, and in cross-section listing all rock types and the mineralization intersected.

Drill core samples were collected in intervals of 1.0 to 2.0 metres. Split drill core saw samples were procured on site and 349 samples, of which 11 were quality control samples, were submitted to ALS Chemex in Vancouver, BC. Core sample descriptions and quality control samples are listed in the drill log spreadsheets in Appendix 1. Refer to Appendix 2 for certificates of analysis (COAs) containing all analytical results for core samples from drillhole Z11-4F1.

Table #2 – Location Data for DDH Z114F1. UTM in NAD 83, Zone 16

Township	Easting	Northing	Elevation	Azimuth	Inclination	Total Depth
Fintry (G-2308)	682500	5545570	130m	0°	-65°	543m

9.0 Sample Preparation Analysis and Security

All core samples were identified with a sample identification (ID) number tag that was placed in the plastic bag with the split core. The sample ID number was also written on the outside of each sealed sample bag. The sample bags were grouped together and placed into larger rice bags. The rice bags were also sealed before being shipped to ALS Chemex Laboratory in Thunder Bay by Zenyatta company employees. At ALS Chemex, all samples were opened, crushed and split into sub-samples and pulverized prior to being sent to Vancouver, British Columbia for analysis. All core samples were analyzed using the ALS Chemex "*ultratrace level 48 multi-element package, ME-MS61*" (see Appendix 2 for results). In addition, 16 core samples were analyzed using the whole rock package *ME-ICP06* (see Appendix 3).

Standards and control samples were inserted into the sample stream in order to test the analytical quality control. The control samples used for drillhole Z11-4F1 are listed below in Table #3:

TABLE #3: DRILLHOLE Z11-4F1 - CONTROL SAMPLES		
HOLE ID	SAMPLE ID	COMMENT
Z114F1	J600340	Control - J601133 Pulp
Z114F1	J600360	Control - J601133 Raw/Reject
Z114F1	J600380	Control - J601133 Pulp
Z114F1	J600160	Control - J601132 PULP
Z114F1	J600180	Control - J601133 PULP
Z114F1	J600200	Control - J601132 PULP
Z114F1	J600220	Control - J601133 PULP
Z114F1	J600240	Control - J601132 PULP
Z114F1	J600299	Control - J601133 Raw/Reject
Z114F1	J600300	Control - J601133 Pulp
Z114F1	J600304	Control - KRA-P

10.0 Interpretation and Conclusions

Zenyatta Ventures has finished the first phase of exploration for Cu-Ni-PGE targets on the Albany claim groups and is proposing to conduct follow-up drilling exploration programs. The preliminary exploration program on the Albany claims, carried out in the winter and spring of 2010, consisted of a Geotech helicopter borne **VTEM 35 survey**. Survey lines were flown north-south with 150 metre spacing. Results of this survey were used to identify high priority EM and magnetic targets for diamond drilling. A total of 26 holes were drilled on eight of the Albany claim blocks, which included one drill hole, Z11-4F1 on Block 4F.

Drill hole Z11-4F1 crossed several distinct graphitic breccia zones which were found to be very conductive and non-magnetic, explaining the geophysical results of high conductivity and a magnetic low. The **conductive zone** is estimated to be 1.4 km long, striking east-west with a north-south extent of 800m. The geophysical results also suggested that this anomaly is likely deeper than was able to be modeled. The observations from DDH Z11-4F1 and the geophysical data would suggest that this is a fairly large graphite deposit which needs to be further tested by a subsequent drilling program.

Based on the results so far, and petrological work conducted by Dr. Andrew Conly at Lakehead University in Thunder Bay, it appears that the graphite was deposited hydrothermally. The most logical possible source for the deposited graphite (carbon) being the younger carbonatite intrusive. But, due to the potential size of the deposit, a better understanding of the source of the carbon and the formation of the brecciated zones is warranted.

11.0 Recommendations

Several zones of high grade graphite mineralization were intersected in drillhole Z11-4F1. The positive results warrant further exploration. A second phase of diamond drilling is recommended to investigate the possibility of graphite mineralization occurring deeper, and to determine the structural extent of the mineralized zones. The following work is recommended:

1. A subsequent drilling program with 200 metre step outs in all directions. The step outs would mainly be east-west, following the presumed strike of the deposit, with at least one hole to the south to determine depth extent of the deposit.
2. Subsequent geophysical 3-D modeling should be undertaken using drillhole data.
3. A bench-scale test should be undertaken by an outside laboratory to assess the purity and flake size of the graphite within the deposit.
4. It is further recommended that Zenyatta fund a graduate student research project to determine the nature of the depositional formation and the source of the carbon.

13.0 Certificates of Qualifications

I, **Glenda Carey**, of 218 London Dr, Thunder Bay, Ontario, do hereby certify that:

- 1.** I hold a **Bachelor of Science Degree in Earth Science (1989)** from Memorial University of Newfoundland, St. Johns, Newfoundland and Labrador;
- 2.** I have practiced my profession in Newfoundland and Labrador, NWT, Alberta, Nunavut and Ontario since 1989 and have been employed directly by mining and exploration companies and the Government of Nunavut, and Government of Newfoundland and Labrador;
- 3.** I am presently an employee for Zenyatta Ventures Limited based in Thunder Bay, Ontario as a Geologist for the company;
- 4.** I have worked on projects similar to that represented by the Albany Project, and have been hired by Zenyatta Ventures Ltd. I consider this report to be accurate in all respects;
- 5.** Permission is granted to Zenyatta Ventures Limited to use this report in a prospectus or other financial offering.

Date: March 30, 2012 at Thunder Bay, Ontario

ZENYATTA - 2011 ALBANY PROJECT

DETAILED LOG

DDH ID	FROM (m)	TO (m)	LITHOLOGY	LITHOLOGY DESCRIPTION
Z11-4F1	0	31	OVERBURDEN	
Z11-4F1	31	36	LOST CORE in CASING	Limestone bedrock reported by drillers. They were instructed to sink casing deeper than standard practice to avoid water loss. Not all rock recovered.
Z11-4F1	36	41.64	LAMINATED LIMESTONE	Non-magnetic light grey fine grained laminated limestone. Laminae about 1-2cm thick; bedding plane at 60-70 CAA. Lower contact sharp @CAA 65.
Z11-4F1	41.64	48.56	LAMINATED LIMESTONE interbedded with BIOCLASTIC LIMESTONE	Similar to 36.00 to 41.64m, but substantially darker (medium to dark grey) interbedded with medium to coarse grained shelly coquina/bioclastic limestone; bedding plane at 60-70 CAA. Most of the coquina is found below 45m as the coquina interbeds become dominant downcore; overall the ratio is 64% laminated limestone and 36% bioclastic limestone. No reefal material was observed. Lower contact with lateritic weathered granitic gneiss is brecciated over 4cm.
Z11-4F1	48.56	60.49	PALEOWEATHERED GRANITIC GNEISS	Based on the downcore unit, this is the grey paleoweathered surface of a granitic gneiss. This unit does not appear to have the carbonate veinlets of the following downcore unit, nor the foliation seen downcore. It is mainly composed of rounded to subangular 0.5-2.0mm quartz (~50%) with considerable chloritic clay and probable fine grained plagioclase or bleached potassium feldspar. It is very friable and breaks easily from 48.56 to 50.09m. This unit is saprolitically weathered down to 60.49 where the rock is chloritized and friable. A quartz-biotite grey gneiss section occurs from 60.03-60.23m and probably was a 20cm xenolith within the granite.
Z11-4F1	60.49	71.68	GRANITIC GNEISS	Non-magnetic, moderately to strongly foliated medium to coarse grained light pinkish grey to pinkish grey granitic gneiss. Compositionally, it is ~60-70% potassium feldspar and ~30% ~1-2 mm wide quartz with nil observed biotite. Potassic overprint along fractures with more than trace amounts of chlorite on fracture surfaces; bright green and green clays occur on thin (<1mm) fractures at 63.67m, 63.74m, 65.18m, 66.86m and 67.00 to 69.60m. Essentially nil sulfides overall, except where described in subunits. Trace submillimeter carbonate veinlets spaced every few cm at various orientations; may simply be groundwater remobilization from overlying limestones along basement fractures. Unit is moderately to strongly foliated @CAA 45-65. -61.70 to 61.75 fine grained aplite vein @CAA70 with 1-2% 1-2mm wide finely disseminated pyrite
Z11-4F1	71.68	74.74	FAULT ZONE	The upcore unit is the host rock of this fault. Due to 40% core loss, it was not possible to accurately determine fracture orientations, of which there were at least two, as the rock fragments were small (1-2cm wide on average). While drilling, this zone caused loss of water return which eventually returned due to the diligent use of muds.
Z11-4F1	74.74	79.78	SYENITE	Massive to fine grained syenite with 10% fine (1mm) black pyroxenes "peppered" evenly throughout. Syenite has the groundmass appearance of a diorite (white to light grey to green, fine grained, igneous groundmass), and the distinctive "peppering" of fine black pyroxenes and commonly has elevated magnetic susceptibility compared to the older graphitic breccia overprinting of the even older Archean granitic gneiss. Regional OGS mapping places the Quetico/Marmion terrane boundary (aka: Quetico Fault) in the vicinity of this drillhole. The graphitic breccias seen in this hole from 80m to at least 537.60m are consistent with being a locally dilatent section of a major structural zone.

ZENYATTA - 2011 ALBANY PROJECT

DETAILED LOG

DDH ID	FROM (m)	TO (m)	LITHOLOGY	LITHOLOGY DESCRIPTION
Z11-4F1	79.78	89.71	GRAPHITIC BRECCIATED SYENITIC GNEISS	Framework supported, >70% granitic gneiss clasts, 2mm to 2cm average, angular, non-magnetic, dark grey with pinkish potassium feldspar. The matrix (3-30%) is composed of fine black grains, some of which are graphite. At 80.91m is a 1cm nodule that may be ultramafic (Iherzolite) and there is a second bright green nodule (2cm) at 81.42-81.44m. Green, possibly ultramafic mantle nodules at margin of graphitic breccias seen at 80.91m and 81.43m. Trace to nil finely disseminated pyrite.
Z11-4F1	89.71	112.5	GRAPHITIC OVERPRINTED SYENITIC GNEISS	Non-magnetic dark grey granitic gneiss with a distinct graphitic overprint (trace to 1% overall) characterized by numerous submillimeter very dark grey highly conductive graphite rich veins. Moderately foliated @CAA 60-65. Feldspars are strongly overprinted with salmon pinkish-orange potassic alteration. There is trace conductive graphite in a few submillimeter veins, confirmed by the ohm meter. Trace finely disseminated pyrite overall; almost 0.5% disseminated and fracture-controlled pyrite (<3mm) from 107m to 108m. -91.60 to 91.79 possible pegmatite or granitic gneiss. Sharp contacts @CAA30 and @CAA45

ZENYATTA - 2011 ALBANY PROJECT

DETAILED LOG

DDH ID	FROM (m)	TO (m)	LITHOLOGY	LITHOLOGY DESCRIPTION
Z11-4F1	112.5	190.5	GRAPHITIC BRECCIATED SYENITIC GNEISS	<p>This section is a similar to the graphitic brecciated syenitic gneiss from 79.83 to 89.71m but with more variation in graphitic matrix percentage, clast size, and alternating between framework and matrix supported. Generally, the unit is s syenitic gneiss with overall graphitic matrix ranging from 3-30%. The matrix is fine, very dark grey to black, with visible graphite as a constituent, and very conductive. Locally the matrix exceeds 50% (ie: 113.30-113.65m). There were some sections which were weakly brecciated where a weak foliation could be determined (@CAA50-60). Trace finely disseminated and blebby pyrite on fracture surfaces. Lower contact a transition zone from ~180 to 190.50 with a decreasing brecciated fraction with decreasing observed graphite-rich material.</p> <p>-113.30 to 113.65m is similar to the larger clast matrix-supported breccia (~60% graphitic matrix overall) described from 144.75 to 165.21m.</p> <p>-122.49 to 124.63 Fault zone: strongly fractured down to 123.34, then weakly fractured below this. Primary fracture @CAA55-60 parallel to foliation, secondary fracturing @CAA5-15 against foliation. Trace to a few percent submillimeter to 4mm wide carbonate veinlets exist throughout the zone, as well as increasing in intensity above the fault, as well as tapering off below it. Host rock is weakly foliated @CAA50-60 and contains 3-10% graphitic material as in adjacent units.</p> <p>-124.63 to 146.45 Similar to 112.50 to 122.49m, but with very consistent clast size range and percent matrix. This is a matrix supported unit (40-70% matrix). The framework is as described upcore, but clasts are significantly larger ranging from a few mm up to 15cm, averaging 2-5cm. Several post-breccia dykes are also present as follows: 134.10-134.60m: aplite dyke with trace fine pyrite. Aphanitic, aphyric mafic dykelets at 139.15-139.28m (@CAA10) and 139.98-140.12m (@CAA20) are possible Matachewan diabases.</p> <p>-146.45 to 148.14 Mafic dyke: dark grey, fine-grained, non-conductive groundmass with <5% rimmed equant green olivine (2-4mm) phenocryst cores with 1-2mm black biotite or amphibole rims and <5% tabular leucite/sanidine phenocrysts (5mm) locally with bevelled terminations and/or Carlsbad interpenetration twinning and/or fine inclusions seen in zoned crystals growth boundaries lokking down the long axis. Contacts @CAA20. Trace finely disseminated pyrite. ALso occurring at: 166.90 to 167.65 and at 169.70 to 172.00</p> <p>-167.65 to 169.70 clast size ranges from 2-5cm down to a few mm wide and matrix ranges from ~55% up to 70-85%.</p> <p>-172.00 to 180.02 clast size ranges from 2-5cm down to a few mm wide and matrix ranges from ~55% up to 70-85%. From 179.62 to 180.02m, very large (8-12cm long) clasts (60-80%) in a framework supported breccia. Lower contact at 180.02m is sharp at 60CA. There are primary euhedral white leucite/sanidine phenocrysts (5mm) in the uniformly milled graphitic matrix suggesting the mafic dykes may have been coeval and post-dating some graphitic brecciation. (ie: phreatomagmatic brecciation).</p> <p>-180.02 to 183.00 Unbrecciated syenitic gneiss, non-mineralized.</p> <p>-183.00 to 190.50 Matrix to framework ratio (and conductivity) decreases abruptly between 183m and 185m due to a proportionate increase in the non-conductive juvenile mafic matrix; leucite/sanidine phenocrysts in the dark matrix are similar to those from 172 to 180.02m above.</p>

DETAILED LOG

DDH ID	FROM (m)	TO (m)	LITHOLOGY	LITHOLOGY DESCRIPTION
Z11-4F1	190.5	253.19	SYENITE	<p>Non-magnetic fine to medium grained light grey to light pinkish grey syenite. From 180.02 down to 193.20, the section can be described as a trachyte, the volcanic equivalent of the syenite; this is a gradational change from the black groundmass of the previous unit to a chilled, light grey leucite or sanidine phryic trachyte that has an increasingly pink tint from 191.5m to 193.2m. These rapid variations are all typical for an intrusion margin such as seen below from 199 to 253.19m. Below 193.20, unit becomes a spotted syenite with numerous mafic dykes; fine grained (<1mm) with 10% fine biotite/amphibole overall. This portion has distinctive coarse (5mm) biotite clumps surrounded by 3-5mm pink potassic rims. No penetrative foliation. No flow foliation. No brecciation. Massive and uniform with essentially nil veining.-188 to 207m potassic-rich (overprinted?) zone, weakly altered at the top, gradually becoming strongly altered at faults from 191.50 to 192m and 195.56 to 195.80, then decreasing downcore to be barely detectable below 207m -191.50 to 192.00m Strongly fractured fault zone with associated submillimeter carbonate veinlets up and downcore at various orientations; due to the strongly fractured nature, fracture orientations with respect to CAA could not be accurately determined. -193.20 to 193.95 Mafic dyke. Generally typical of the dykes in this hole with the following features. Groundmass is medium grey and aphanitic. Green olivine phenocrysts (5%, 3mm) have black amphibole rims. Orange feldspathoid (5%) phenocrysts are up to 1cm by 3cm but show no flow orientation. Dyke shows no brecciation. Possible chill margin from 193.85 to about 199m has rare olivine and feldspar/feldspathoid phenocrysts in a medium grey, aphanitic groundmass.</p> <p>Contact at 193.2m is sharp at 45CA. Contact at 193.85m is sharp at 10CA. -195.56 to 195.80m strongly fractured fault zone with associated submillimeter carbonate veinlets up and downcore at various orientations. Due to the strongly fractured nature, fracture orientations with respect to CAA could not be accurately determined. -219.63-219.74 Green mafic dyke with sharp contacts @CAA80 containing microlites.</p> <p>-219.95-220.31 Black aphyric, aphanitic mafic dyke without chill margins but has sharp contacts @CAA70.</p> <p>-244.71-248.25 Very fine grained mafic dyke with microlites and 1% feldspar phenocrysts (1-2mm) in contact margins plus from 246.5 to 248.25m there are three xenoliths (30%) of the host syenite. (The significance to this microlitic mafic dyke observation may be that it is Phanerozoic).</p>

DETAILED LOG

DDH ID	FROM (m)	TO (m)	LITHOLOGY	LITHOLOGY DESCRIPTION
Z11-4F1	253.19	272.28	GRAPHITIC BRECCIATED SYENITIC GNEISS	Mainly a graphitic brecciated syenitic gneiss alternating with unbrecciated but graphitic overprinted sections of syenitic gneiss. Rounded/milled medium grained (<10mm) granitic gneiss clasts (<30cm) in black matrixes. From 253.19 to 263.8m, the matrix is an olivine-feldspar porphyritic lamprophyre with an aphanitic to very fine grained groundmass that may also be comagmatic to the adjacent nepheline syenite unit from 272.28-329.85m. Non-conductive lamprophyric matrix to the breccia occurs at 253.19-253.26m, 253.35-253.45m, 253.49-253.60m, 253.63-253.90m, 254.0-254.24m, 254.64-254.81m, 255.29-255.47m, 255.74-255.75m, 256.0-256.06m, 256.20-256.29m, 256.36-256.40m, 256.50-256.58m, 256.58-256.88m, (50% 4-6cm patches of gneiss and dyke), 257.40-258.06m, 258.51-259.06m, includes later mafic dykes (dark green, chilled margins, trace pyrite) at 60-90CA at 258.74-258.78m and 259.06-259.12m (light green, chilled margins); 259.52-260.42m, 262.28-262.31m, 260.40-262.93m, 263.2-263.8m with a dark green, fine grained mafic dyke at 263.56-263.71m and a moderate pervasive epidotization patch from 263.71-263.8m adjacent the dyke. Non-porphyritic black matrix with locally conductive graphite patches occur from 263.8-272.28m. It has more angular and smaller (1mm-20cm) clasts (50%) than igneous matrix breccia. From 268.5 to 272.28m there is mostly granitic gneiss blocks with milled black matrix breccia sections at 269.16-269.18m, 269.96-270.15m and 271.3-271.73m. Dykelets of orange potassiac, fine grained aplite with 5% biotite and trace disseminated pyrite and pyrrhotite occur at 264.41-264.45m (70CA) and 266.49-266.53m (50CA). A moderate pervasive epidotization patch from 263.71-263.8m adjacent the dyke. At 257.4-257.61m: pink potassiac alteration of granitic gneiss block with trace (0.1%) fine disseminated pyrite within the dyke breccia groundmass. Essentially nil to very trace pyrite overall. Exceptions are: At 257.4-257.61m: pink potassiac alteration of granitic gneiss block with trace (0.1%) fine disseminated pyrite within the dyke breccia groundmass. Mafic dykes at 258.74-258.78m and 259.06-259.12m with trace pyrite. Dykelets of orange potassiac, fine grained aplite with 5% biotite and trace disseminated pyrite and pyrrhotite occur at 264.41-264.45m (70CA) and 266.49-266.53m (50CA)
Z11-4F1	272.28	329.85	SYENITE	light green-grey, fine grained (1-3mm), massive, uniform intrusion with 1-5% fine 9<1mm) black pyroxene peppered on the equigranular groundmass. Nepheline syenite composition to be checked with wholerock geochemical analysis as the initially logged lithology was diorite. MAFFIC DYKES occur at: 273.05 to 273.75m, olivine porphyritic mafic dyke with contacts at 70CA. Medium green-black olivine (5%, 1-4mm) with 1-2mm black amphibole rims and rare (one) 5mm leucite or sanidine phenocryst in a very fine grained groundmass. Similar mafic dykes occur at 287.96-287.97m, 288.03-288.06m, 288.15-288.25m, 288.51-288.52m, 288.58-289.36m, 327.63-327.74m (35CA and 70CA chilled contacts), 327.83-327.97m (70CA and 45CA chilled contacts), 328.60-328.64m (50CA and 85CA chilled contacts). A light brown dyke (60CA) from 322.7m to 322.95m has leucite or sanidine phenocrysts. At 324.06m is a 1cm feldspathoid-rich magmatic layer within the intrusion that contains several 1-3mm pyrrhotite grains. This unit ends with a contact zone from 325.12m to 329.85m that includes xenoliths of gneissic granite from 325.12-326.4m, 327.33-327.63m, 327.74-327.83m, 327.97-328.60m, 328.64-328.97m.

DETAILED LOG

DDH ID	FROM (m)	TO (m)	LITHOLOGY	LITHOLOGY DESCRIPTION
Z11-4F1	329.85	377.7	GRAPHITIC BRECCIATED SYENITIC GNEISS	Grey Syenitic gneiss clasts (70%) in black conductive graphitic matrix (30% overall matrix) with the graphite being estimated at <5% of the overall matrix (ie: <1.5% graphite overall). Post-brecciation nepheline syenite dykes (light grey to green with 5% pyroxenes peppered throughout) occur at 335.54-335.95m and 338.32-341.6m (85CA). Post-brecciation aplite dykelets containing trace pyrite (pink, fine grained (1mm)) occur at 65CA to 90CA at: 343.71-343.81m, 344.06-344.10m, 344.43-344.45m, 372.35-372.37m (90CA), 373.92-373.94m and at 373.51-373.77m a dykelet with 1% pyrite and weak pink potassic alteration (1% feldspathoid phenocrysts; 1mm*5mm). At 355.0 to 357.76m is a light green mafic dyke at 70CA. large inclusions of granitic gneiss in the breccia occur from 357.76 to 359.16m and from 359.53m to 360.19m. A very fine grained mafic dyke with 1% feldspathoidal phenocrysts (1mm*4mm) from 361.54m to 362.1m has <1cm chilled margins, 70CA). From 377.17m to 377.40m is a black, biotite (1mm) lamprophyre dyke that is non-conductive. At 376.0-377.17m is weak pervasive and fracture-controlled pink potassic flooding adjacent the intrusion from 377.7 to 399.94m but there is no increased pyrite content which is essentially nil to trace very very fine grained rare pyrite specks. At 338.6 to 339m is pink, weak pervasive potassic flooding with trace pyrite overall and as pink (2mm) rims to 1% 5mm black biotite clusters as spots. At 373.51-373.77m, an aplite dykelet has weak pink potassic alteration and 1% pyrite. Post-brecciation aplite dykelets contain trace pyrite at 343.71-343.81m, 344.06-344.10m, 344.43-344.45m, 372.35-372.37m (90CA), 373.92-373.94m. An aplite dykelet at 373.51-373.77m has 1% pyrite in weak pink potassic alteration. At 376.0-377.17m is very very fine grained rare pyrite specks.
Z11-4F1	377.7	399.94	SYENITE	10%-15% fine black pyroxene peppered throughout a massive uniform overall layered syenitic intrusion. Minor primary, flat-lying, igneous layers at 60CA observed overall (eg: 393.57m). A black chilled margin occurs from 377.70 to 377.83m at 65CA. There are pink feldspathoidal sweat-outs with biotite (5mm) at 381.59-381.61m, 382.08-382.14m, 382.51-382.59m, 383.3-383.4m, 383.66-383.79m, 384.35-384.89m. The intrusion is cut by a late, fine grained mafic dykelet with 1% feldspathoidal lath phenocrysts (1mm * 4mm) at 385.23m to 385.28m. A black chilled margin occurs from 377.70 to 377.83m at 65CA. Minor primary, flat-lying, igneous layers at 60CA observed overall (eg: 393.57m). From 380.2-390m: weak pervasive pink potassic alteration tint to intrusion includes trace to 0.2% fine disseminated pyrite overall. A section from 381m to 382m has moderate to strong fracture controlled pink potassic alteration. From 380.2-390m: weak pervasive pink potassic alteration tint to intrusion includes trace to 0.2% fine disseminated pyrite overall.

ZENYATTA - 2011 ALBANY PROJECT

DETAILED LOG

DDH ID	FROM (m)	TO (m)	LITHOLOGY	LITHOLOGY DESCRIPTION
Z11-4F1	399.94	441.6	GRAPHITIC BRECCIATED SYENITIC GNEISS	<p>Black fractured granitic gneiss with black matric graphitic brecciation at 400.48-400.68m, 400.98-401.17m, 401.72-401.78m, 401.95-402.3m, 402.5-403.05m, 404.15-405.2m, 405.32-405.37m, 405.7-405.78m, 406.1-406.15m, 406.25-406.38m. A late aplite dyke at 404.35-404.4m is post brecciation. Graphitic breccia sections are 36% of this syenitic gneiss unit. Trace pyrite observed at 402.57m and 402.88m in graphitic breccia matrix.</p> <p>-407.50 to 411.58 A uniform, green, fine grained nepheline syenite intrusion from 408.2 to 411.17m has chilled margins and contact zones as follows: 407.50-407.58m = a black chilled margin then from 407.58 to 407.70m is a xenolith of granitic gneiss then a black contact zone with 1cm wide irregular and wormy margined green siliceous veins from 407.7m to 408.2m. The lower contact has a chilled margin from 411.17m to 411.42m then fine grained nepheline syenite from 411.42-411.58m. Chilled margins and contact zones from 407.5m-408.2m and 411.11m to 411.58m. Odd textured veins from 407.7 to 408.2m. -411.58 to 441.60 Syenitic gneiss fractured and cut by graphitic brecciation. A light green mafic dyke post-dating brecciation occurs from 425.50m to 426.35m. Post brecciation lamprophyre dykes with olivine (5%) and leucite/sanidine (5%) occur at 431.45-432.00m and 432.70-434.15m. Black, fine grained biotite lamprophyres with either 2% (<1mm) biotite or biotitic margins occur at 414.70-414.80m(margins), 422.57-422.80m and 436.10-436.21m. Chilled margins in late dykes. The largest unbrecciated section of granitic gneiss is from 437.4m to 440.83m where it is massive, uniform, has a weak gneissic fabric, and has trace pink alteration about some fractures. There is a graphitic breccia contact zone from 440.83-441.6m.</p>
Z11-4F1	441.6	456.67	MAFIC DYKE	Medium grey and aphanitic with green olivine phenocrysts (5%, 3mm) having black amphibole rims. Lower contact margin with 5% zoned, grey core and white-rimmed 1cm leucite/sanidine euhedral phenocrysts commonly with Carlsbad twinning and 3% 5mm green olivine-cored phenocrysts almost completely converted to black amphibole rims (>2mm thick) in a magnetic, massive, uniform, medium grey hypabyssal igneous groundmass of possibly ultramafic composition. Very fresh-looking. No quartz. Leucite/sanidine phenocrysts are restricted to intrusion margins and olivine occurs throughout the unit. Black amphibole rims about green olivine. Unit is very "fresh looking".
Z11-4F1	456.67	458.4	GRAPHITIC BRECCIATED SYENITIC GNEISS	Light grey xenoliths with dark grey, localized conductive graphitic pneumatolitic breccia veins (456.77-457.0m, 457.47-457.70m, 458.1-458.18m) that are associated with the above intrusive phase from 441.6 to 456.67m. The contact zone is principally (90%) the granitic gneiss/granophyre from the unit below that has been brecciated and occurs as xenoliths in the chilled margin of the lamprophyre. No penetrative foliation. No flow foliation. Brecciation is pneumatolitic in producing angular clasts from in situ brecciation and it is phreatomagmatic as there is juvenile lamprophyric matter in the matrix. There is enough graphite locally in the brecciated matrix to be conductive but the overall graphite content is trace. Interpreted contact relationships place the granophyre/granitic gneiss in the unit below as being older than its adjacent lamprophyre from the unit above which would make the graphitic phreatomagmatic brecciation coeval with this lamprophyre.

ZENYATTA - 2011 ALBANY PROJECT

DETAILED LOG

DDH ID	FROM (m)	TO (m)	LITHOLOGY	LITHOLOGY DESCRIPTION
Z11-4F1	458.4	467.3	SYENITE	The top of the unit (down to 466.20m) is granitic looking but it is not clear if the lack of well developed gneissosity was lost during contact metamorphism; two nepheline layers of medium grey, coarse grained (1cm), tightly packed nepheline (?) with leucite/sanidine (?) in marginal zones occur at 459.3-459.6m and 460.66-461.4m. Multiple layers as follows: 458.3-459.3m: granophyre with almost nil pyrrhotite (<0.001% po) as rare specks (<1mm). 459.3-459.6m: nepheline (initially considered anorthosite) with nil sulfides and trace leucoxene at lower contact. 459.6-460.66m: nepheline syenite, medium grey-green, very fine grained, 10% black 1mm pyroxenes peppered throughout with 0.5% uniformly disseminated very fine grained pyrrhotite (<0.5mm). 460.66-461.4m: nepheline, several 1mm pyrrhotite grains at 461.1m and a few isolated very fine pyrrhotite disseminations. 461.4-462.3m: nepheline syenite, fine grained, medium grey-green, 10% black peppered pyroxene, <0.01% very fine pyrrhotite disseminations and along fractures. 462.3-464.6m: nepheline syenite, black, 20% black peppered pyroxene layers (<15cm, 50% overall, 60CA) and medium grey-green nepheline syenite layers (<15cm, 50% overall, 60CA) with essentially nil sulfides (a hairline pyrrhotite fracture at 464.2m). 464.6-466.2m: nepheline syenite, medium grey green, 10% peppered pyroxenes, essentially nil sulfides. 466.2-467.3m: nepheline, light grey, 90% nepheline laths 1-5mm aligned to magmatic layering at 65CA with 0.5% finely disseminated interstitial pyrrhotite overall. Essentially nil sulfides overall with the following exceptions: 458.3-459.3m: granophyre with pyrrhotite (<0.001% po) as rare specks (<1mm). 459.6-460.66m: nepheline syenite with 0.5% uniformly disseminated very fine grained pyrrhotite (<0.5mm). 460.66-461.4m: nepheline, several 1mm pyrrhotite grains at 461.1m and a few isolated very fine pyrrhotite disseminations. 461.4-462.3m: nepheline syenite, <0.01% very fine pyrrhotite disseminations and along fractures. 462.3-464.6m: nepheline syenite, with a hairline pyrrhotite fracture at 464.2m. 466.2-467.3m: nepheline with 0.5% finely disseminated interstitial pyrrhotite overall.

ZENYATTA - 2011 ALBANY PROJECT

DETAILED LOG

DDH ID	FROM (m)	TO (m)	LITHOLOGY	LITHOLOGY DESCRIPTION
Z11-4F1	467.3	487.8	GRAPHITIC BRECCIATED SYENITIC GNEISS	From 467.3-472.8m: in situ to locally brecciated nepheline syenite (<1cm angular clasts), black, aphanitic to very fine grained matrix with locally conductive, trace graphite overall from a 5-10% matrix overall. Crossed by 2-20mm pink tinted, post-breccia granophytic (medium grained) veins every 0.5m, About 0.5% pyrrhotite overall as fine disseminations (<1mm), in hairline veinlets and as a 3mm droplet at 468.9m. A few pyrite grains also present overall. Trace graphite overall as a component in locally conductive breccia matrix (5-10% matrix). About 0.5% pyrrhotite overall as fine disseminations (<1mm), in hairline veinlets and as a 3mm droplet at 468.9m. A few pyrite grains also present overall. From 474.65 to 478.00 breccia contains relict nephelinite limited to black fractured white nepheline or leucite/sanidine rhombs up to 1cm long (476.9m) in a black, generally conductive, graphitic aphanitic matrix with rare coarse angular pyrrhotite grains noted at 477.13m (2mm by 15mm) and 477.47m (10mm). Black graphitic matrix breccia with post-breccia, pink (3mm to 30mm thick) granophytic veins every 0.5m. Brecciation as fractures continues in next unit to 478.7m. At 476.33m is a 1cm thick network vein of graphite (30%) wrapped around crystals. Trace pyrrhotite overall (0.1% po, <1mm specks) and as coarse angular pyrrhotite grains at 477.13m (2mm by 15mm) 477.47m (10mm). From 480.90 to 487.80, the unit is a phreatomagmatic breccia that has 40% sections of aphanitic mafic black matrix and about 60% angular clasts. The margin from 480.9 to 481.7m has 10 to 18cm xenoliths of the adjacent nepheline syenite and basement gneiss in a black chill margin. About 40% of the sections of black breccia matrix is conductive but only locally (40%) where there are graphite slips or a graphite network vein (30% graphite) as at 487.7 to 487.8m along a narrow fault. Overall estimated graphite in black matrix is 40% so the overall estimated graphite component is 5% (40% *40% * 40%). From 481.9 to 485.2m is a fine grained mafic dyke with trace olivine and leucite/sanidine phenocrysts associated with pyrrhotite and arsenopyrite mineralization. From 482 to 485m, are pink-tinted, feldspathoidal dykelets in a plexus of multiple orientations. From 481.9 to 485.2m is a fine grained mafic dyke with trace olivine and feldspar phenocrysts associated with pyrrhotite and arsenopyrite mineralization. A 15mm by 20mm angular pyrrhotite at 483.76m and a 4mm by 10mm angular pyrrhotite at 484.87m are related to the trace (0.1%) overall very fine grained pyrrhotite disseminations and broken hairline veinlets in the groundmass. From 482 to 485m, are pink-tinted, feldspathic dykelets with axial pyrite. Whiter pyrite or arsenopyrite occur at 482.15m and 483.55m. -472.80 to 474.65 Nepheline syenite (no graphitic overprint observed): 6mm grey, equant, nepheline (>90%) tightly packed with trace <0.1% very fine pyrrhotite disseminations overall. 10% peppered pyroxenes (1mm) in a fine grained groundmass. 473.75-473.9m: trace pyrrhotite overall as very fine disseminations (0.1% po) and as 1mm pyrrhotite grains in two 1-3cm veinlets. Trace <0.1% very fine pyrrhotite disseminations overall. -478.00 to 480.90 Nepheline syenite (no graphitic overprint observed): Medium to coarse grained (<1cm) nephelinite with local crushing and black, mainly non-conductive fractures to 478.7m. Trace (<0.1%) very fine disseminated pyrrhotite. 10% peppered pyroxenes (1mm) in a fine grained groundmass. Essentially nil sulfide overall except for three pyrrhotite droplets (2mm) at 479.92m. Local crushing and black, mainly non-conductive fractures to 478.7m. Trace (<0.1%) very fine disseminated pyrrhotite; three pyrrhotite droplets (2mm) at 479.92m.
Z11-4F1	487.8	506	NEPHELINE SYENITE	massive, uniform, light pink-grey, fine grained (<1mm) nepheline syenite with 15% fine (1mm) black pyroxenes "peppered" evenly throughout and a few larger (<4mm) nepheline phenocrysts throughout (eg 487.7-488.6m). No black graphitic brecciation. At 492.67 to 493.06m is a medium green-grey mafic dyke with sharp chilled contacts at 45CA (492.67m) and 70CA (493.06m). Dyke contains an angular (3mm*6mm) pyrrhotite clot 2cm from uphole contact (at 492.69m) and a discontinuous pyrrhotite seam/veinlet (1mm by 25mm) along the contact (492.67m). At 500.0 to 501.07m is a medium green mafic dyke with sharp contacts at 85CA (500m) and 75CA (501.07m). Nil sulfides in this dyke. Dyke is similar to adjacent nepheline syenite but matrix is medium green with 15% 0.5mm pyroxenes. Essentially nil sulfide overall. Dyke contains an angular (3mm*6mm) pyrrhotite clot, 2cm from uphole contact (at 492.69m) and a discontinuous pyrrhotite seam/veinlet (1mm by 25mm) along the contact (492.67m).

ZENYATTA - 2011 ALBANY PROJECT

DETAILED LOG

DDH ID	FROM (m)	TO (m)	LITHOLOGY	LITHOLOGY DESCRIPTION
Z11-4F1	506	522.54	GRAPHITIC BRECCIATED SYENITIC GNEISS	About 60% graphitic, matrix-supported to in situ breccia (70% 1mm to 20mm angular clasts in a 30% black conductive matrix. About 40% of the in situ breccia is clasts are larger than the BQ core diameter). The shattered rock is uniform, massive, medium to coarse grained (<1cm) nepheline without the black (1mm) pyroxene peppering. A few pink potassic veins occur from 507.7m to 520.0m with trace pyrite associated as rare, isolated, 2mm grains about 2 to 3 grains per meter concentration. Essentially nil sulfide overall with the most notable exception being from 514.0 to 514.25m where the 30% black graphitic matrix is 5% pyrite in almost filled vugs (up to 5mm by 20mm). About 1.5% pyrite overall within this short interval that includes a well rounded lithic clast (4cm). Nepheline syenite units at 487.8 to 506m and from 522.54 to 525.3m are post-breccia intrusions.
Z11-4F1	522.54	537.6	NEPHELINE SYENITE	Massive, uniform, nepheline syenite with 15% black 1mm pyroxenes peppered throughout section from 522.54 to 525.1m. then is gradational to a distinctive xenolithic section from 524.75 to 537.60m with 1-4cm rounded, black, fine grained xenoliths (Noril'sk taxite). A section from 525.9 to 527.2m has almost no xenoliths and a medium grained diabasic texture. A subsection from 535.1 to 537.6m of leucocratic groundmass to large (<60cm) xenoliths/autoliths. The black xenoliths are moderately rounded with distinct edges. The more xenoliths present, the less black pyroxene peppering. Sharp upper contact (522.54m; 65CA) with breccia and partial alignment of feldspar microlites (65CA) near 526m suggests a subhorizontal magmatic cumulate layering. Lower contact at 537.6m is sharp with the gneiss. Essentially nil sulfide overall. A 3mm by 10mm pyrrhotite at 523.05m and a hairline (<1mm) pyrrhotite veinlet (527.27 to 527.47m, 10CA) are rare examples of sulfides in this unit.
Z11-4F1	537.6	543	GRANITIC GNEISS	Light to medium grey, coarse grained quartz-feldspar-biotite gneiss with pink tints locally(5mm) about fractures. Gneissic layering at 60CA. Essentially nil sulfides overall but there are bright pyrite veneers on fractures at 540.33m (40CA), 541.96m (45CA) and 542.10m (40CA)
