1.0 INTRODUCTION

In the spring of 2015, Oban Mining Corp ("Oban") flew a LIDAR and airborne magnetic survey over the Miller property. In May and June, 2015 Oban retained the services of Orix Geoscience Inc. to map the Miller property located in Boston, Pacaud, McElroy, and Catharine townships. The program consisted of property mapping at 1:500 to 1:1000 as well as 1:100 mapping and channel sampling at the historic Planet Syenite trench. Based on the mapping, a 4, 066m drill program was completed on the property from July to September 2015.

2.0 PROPERTY DESCRIPTION, LOCATION AND ACCESS

The Miller Property consists of 30 claims, 2 patents and extends for 5 kilometers through the townships of Catharine, Boston, Pacaud and McElroy, between the towns of Englehart and Kirkland Lake in northeastern Ontario. The Property is located 10 kilometers north of Englehart, 15 kilometres southwest of Larder Lake and 25 kilometers southeast of Kirkland Lake. The property is situated within the areas covered by National Topographic System (NTS) map sheets 32D/04 and 31M/13. The centre of the property is located at approximately 582900mE and 5318000mN, NAD83 Zone 17N.

The property consists of 30 unpatented contiguous claims, owned 100% by Northstar Gold Corp. ("Northstar"), and cover 1,040 ha, Table 1 and Figure 2. On February 22, 2015 Oban entered into a joint

venture agreement with Northstar which allows Oban to acquire up to 70% interest in the Miller property.

The surface rights for the mining claims are owned by the crown with the exception of 11 Surface Rights Only patents which are not owned by Northstar, Table 3. The property also contains 2 Freehold Patents, L17916 (PIN 61250-0076, Parcel 323SST) and L17917 (PIN 61250-0075, Parcel 322SST), which contain both mining and surface rights and cover 15.83 ha each for a total of 31.67 ha, Table 2.

The property can be accessed via secondary and tertiary roads that exit from Highway 11 and 112. The western portion of the property can be accessed by turning east on local road 564 to Boston Creek and then taking various logging roads. The property can also be accessed via the Wawbewawa Road off of Highway 11, approximately 5km north of Englehart. The Property is located 10 km north of Englehart, 15 km southwest of Larder Lake and 25 km southeast of Kirkland Lake.

3.0 HISTORY

Recorded exploration work on the Property dates back to 1915 with the discovery of the No.1 Vein, located approximately 400 m south of the Allied intrusion. This Vein was explored by Miller-Independence Mining Ltd. and work included 6 shafts sunk to depths of 110 to 515 feet (French, 1988). Much of the historical drilling on the property is concentrated in the area of the No.1 Vein often referred to as the Miller Independence (Figure 3). There are no assessment reports available for the early exploration and development work, however a report by G.B. French in 1988 summarized work completed, and the geological information gathered, prior to 1937. Table 4 summarizes exploration work completed on the property extracted from the Ontario MNDM assessment file database.

Table 4: Summary of Historical Work

Year	Company	Location	Description
1915	Miller-Independence Mining Ltd	Miller Independence	First discovery of gold in vein (No.1 Vein), which cut across the property in a northwest-southeast direction for at least half of a mile. Gold and tellurides occur all along the entire length.
1916	Miller-Independence Mining Ltd	Miller Independence	Quartz vein with free gold and sulphides discovered near the first discovery. A shaft was built near the original discovery. A flat, faulted vein estimated to contain 1,800 tons of ore was discovered. The gold is associated with galena and copper telluride.
1917	Miller-Independence Mining Ltd	Miller Independence	Another shaft was built at a second vein, which was thought to be related to the first vein discovered in 1916. A feldspar porphyry dyke cuts through the shaft.
1917	Miller-Independence Mining Ltd	Miller Independence	Another vein was discovered - it was 6 inches wide at surface and widens up to 10 inches at depth. The vein was alongside a porphyry dyke, both of which carried visible gold and tellurides.
1918-1920	Miller-Independence Mining Ltd	Miller Independence	A total of 6 shafts were sunk on the property. Shaft A was 515 feet and did not cut any vein. Shaft B cut a vein at 21 feet (vertical length). A 174 feet drift was developed south of the vein. The Incline Shaft was 141 feet with east and west drifts constructed. Shaft C was a total of 110 feet. It crosscut a vein and a 30 inch wide mud seam at 44 and 62 feet, respectively. Shaft D had a total depth of 500 feet and crosscut Vein D. North of Vein D are four parallel fractures carrying grades. At the 500-foot level, several iron and copper sulphides rich stringers were cut. The Jumbo Shaft was a 14 feet pit, which followed a 30 inch wide vein. The Jumbo Vein is 400 feet south of Vein D. Both Vein D and Jumbo Vein dip south and strike about 30 degrees north of east. In 1918, 58.0 oz Au and 70.0 oz Ag from 31 ton bulk sample of 1.89 oz/ton Au recovery grade was produced.
1920s	Local Prospector – Authier	Planet Syenite	Gold was discovered at the Planet syenite.
1934	Miller-Independence Mining Ltd	Miller Independence	The mine re-opened and further development was conducted at Shaft C - 185 feet of cross cuts, 1,049 ft of drifting and deepening to 150 feet. 1,000 ft of diamond drilling was also completed.
1937-1938	Planet Gold Mines Ltd	Planet Syenite	Quartz veins and stringers with the presence of visible gold were observed to crosscut the syenite porphyry. Exploration work included extensive trenching, test pitting and diamond drilling.
1938	Howey Gold Mines	Planet Syenite	Howey Gold Mines optioned the Planet property from Planet Gold Mines Ltd. Extensive trenching was performed on the Planet syenite and a 16 ton bulk sample was taken, the results are unknown. A 3,668 lb sample was also taken and it graded 0.075 oz/ton. Recovery was estimated to be 87%
1939	Howey Gold Mines	Planet Syenite	A 3,044 lb sample was taken (probably from the small prospect shaft). The table test indicted a total gold content of 0.096 oz/ton.
1946	Lebon Gold Mines	Planet Syenite	Diamond drill program and surface trenching was performed, results are not available.

4.0 GEOLOGICAL SETTING AND MINERALIZATION

4.1 Regional Geology

The following description of the Abitibi greenstone belt is from Ayer et al. (2002, 2005) and Thurston et al. (2008) and the references found in those papers. The Abitibi greenstone belt is composed of east-trending synclines of mainly volcanic rocks and intervening domes cored by synvolcanic and/or syntectonic plutonic rocks (gabbro-diorite, tonalite, and granite) alternating with east-trending bands of turbiditic wackes (Figure 4). Most volcanic and sedimentary rocks dip vertically and are generally separated by east-trending faults with variable dips. Some of these faults, such as the Porcupine-Destor fault, display evidence for overprinting deformation events including early thrusting, later strike-slip and extension events. There are two ages of unconformable successor basins, early, widely distributed "Porcupine-style" basins of fine-grained clastic rocks, followed by later "Timiskaming-style" basins of coarser clastic and minor volcanic rocks which are largely proximal to major strike-slip faults (e.g. Porcupine-Destor, Larder-Cadillac). Numerous late-tectonic plutons of syenite and gabbro to granite composition, with lesser dikes of lamprophyre and carbonatite, cut the belt.

Metavolcanic and metasedimentary rocks of the Abitibi greenstone belt have been subdivided into a series of assemblages. The Pacaud assemblage is the oldest supracrustal unit in the southern Abitibi, with rhyolites ranging from 2747-2736 Ma. It occurs on the flanks of the Round Lake batholith with a basal intrusive contact with granitoid units (Figure 4). The thickest remnant of the Pacaud assemblage occurs in the Shining Tree area where it is comprised of tholeiitic mafic volcanic rocks with lesser komatiite and calc-alkaline intermediate to felsic volcanic rocks. Units of the 2730-2724 Ma Deloro assemblage occur as homoclinal panels overlying the Pacaud assemblage on the northeastern flank of the Round Lake batholith, and on the northern flank of the Ramsey-Algoma batholith in the Shining Tree and Swayze areas. The Deloro assemblage is composed of calc-alkaline flows and pyroclastic rocks capped by a sedimentary zone consisting of regionally extensive iron formation and related hydrothermal breccias and debris flows. The 2723-2720 Ma Stoughton-Roquemaure assemblage, characterised by broad regions of tholeiitic basalts, komatiitic basalts, and komatiites with several relatively minor felsic volcanic centers, is located on the northeast flank of the Round Lake batholith.

South of Kirkland Lake, the Stoughton-Roquemaure assemblage is interpreted to be underlain by the Pacaud assemblage, which represents a 13 Ma depositional. The upper part of the Stoughton-Roquemaure assemblage in this area, formerly referred to as the Catherine Group, is overlain by felsic volcanic rocks of the Skead Group which is part of the Upper Blake River assemblage indicating a ~20 Ma depositional. Overlying the Stoughton-Roquemaure assemblage, is the Kidd-Munro assemblage which has been subdivided into the 2719-2717 Ma lower part comprised of dominantly intermediate to felsic calc-alkaline volcanic rocks, and the 2717-2711 Ma upper part consisting of tholeiitic and komatiitic units with graphitic metasedimentary rocks and localized felsic volcanic centers. The 2710-2704 Ma Tisdale assemblage overlies the Kidd-Munro assemblage, and has been divided into the lower and upper parts. Mafic tholeiitic flows with locally developed komatiite and intermediate to felsic calc-alkaline volcanic rocks and iron formation of the lower part are interpreted to range in age from 2710 to 2706 Ma m based in part on an age of 2710.1 ± 3.9 Ma for a heterolithic tuff breccia in Boston Township. The upper part of the 2706-2704 Ma Tisdale assemblage is comprised of calc-alkaline felsic to intermediate volcanic rocks and iron formation. Units of the 2704-2701 lower and 2701-2696 upper Blake River assemblage overlie units of the Tisdale assemblage. The upper part of the assemblage includes the Skead Formation which is comprised of calc-alkaline intermediate to felsic volcanic rocks overlying the Stoughton-Roquemaure assemblage on the eastern and southern flanks of the Round Lake batholith.

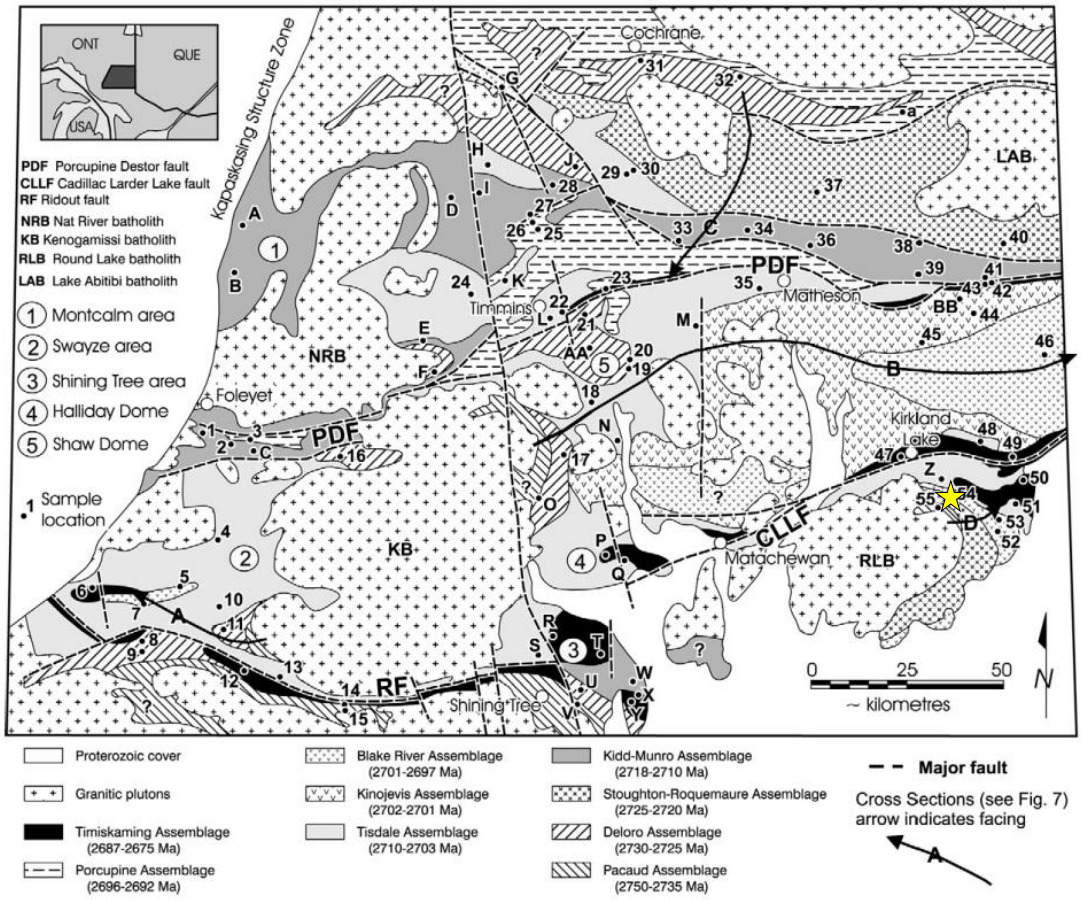

Figure 4: Regional geology of the southern Abitibi greenstone belt (Ayer et al. 2002)

There are two types of successor basins are present in the Abitibi greenstone belt: the early Porcupine assemblage and the late Timiskaming assemblage. The 2690-2685 Ma age Porcupine-type basins contain wacke-dominated, kilometre-scale sequences unconformably overlying the older metavolcanic and sedimentary rocks and are transitional into much more extensive basins (e.g. Pontiac subprovince). The age of the Porcupine sediments is based on the age of the basal Krist volcanic unit and detrital zircons in the overlying wackes in the Timmins area. The depositional environment was interpreted to be a submarine environment due to the lack of regolith or paleosol. The 2677-2670 Ma Timiskaming assemblage includes alluvial-fluvial conglomerates, sandstones, turbidites, and alkalic to calc-alkaline volcanic rocks that unconformably overlie metavolcanic rocks and/or Porcupine assemblage units.

The plutonic rocks of the Abitibi greenstone belt have been subdivided into synvolcanic, syn-tectonic and post-tectonic intrusions. The synvolcanic intrusions were further subdivided in to felsic to intermediate and mafic to ultramafic intrusions. Felsic to intermediate synvolcanic intrusions range in age from about 2745–2696 Ma and coeval with, and geochemically similar to, the volcanic assemblages. These intrusions predate significant compressional strain, are typically foliated tonalite to granodiorite, and are found predominantly within the larger granitic complexes (e.g. Ramsey–Algoma, Round Lake). Mafic to ultramafic synvolcanic intrusions range from approximately 2740–2700 Ma and mainly occur as peridotite to gabbro and diorite sills or lenticular units that cut stratigraphy at a low angle. Syn-tectonic plutons may be related to the deformational events and can be subdivided into early and late series. Early 2695–2685 Ma tonalite, granodiorite, diorite and feldspar±quartz porphyries with adakitic geochemistry similar and coeval to the Porcupine assemblage volcanic rocks occur as stocks within the greenstone belt

and as major portions of the surrounding batholithic complexes. Late 2680–2672 Ma syntectonic intrusions are broadly coeval with the Timiskaming assemblage, and are relatively small, occurring in close proximity to the main faults (e.g. Larder Lake - Cadillac deformation zone). These intrusions are typically alkalic, consisting of monzonite, syenite and albitite with the more mafic phases including diorite, gabbro, clinopyroxenite, hornblendite and lamprophyre. Late-tectonic intrusions range in age from about 2670–2660 Ma and are typically massive and occur within batholiths and the greenstones. They consist of “Algoman” biotite granite, pegmatite and biotite-muscovite S-type granite.

A number of mafic dyke swarms cut the rocks of the Abitibi greenstone belt (Osmani 1991). The 2454 Ma Matachewan dykes are north-trending, vertical to sub-vertical and composed of quartz diabase and commonly contain plagioclase phenocrysts up to 20 cm in length. Northeast-trending quartz diabase of the 2167 - 2171 Ma Biscotasing dykes are lithologically similar the Matachewan dykes although lack the coarse plagioclase phenocrysts (Halls and Davis, 2004). West to northwest-trending, vertical dykes of the 1238 Ma Sudbury dyke swarm are generally medium to coarse-grained with ophitic to subophitic textures olivine tholeiites. The 1140 Ma east to northeast-trending olivine gabbro to monzodiorite dykes of the Abitibi dyke swarm may be related to the Keewanawan Midcontinent Rift event.

Supracrustal units in the Abitibi greenstone belt are dominated by east-west striking volcanic and sedimentary assemblages and east-trending Archean deformation zones and folds. Larger batholithic complexes external to the supracrustal rocks (e.g. Round Lake) represent centres of structural domes. The intervening areas define belt-scale synclinoria that deformed during a number of distinct periods. This pattern is interrupted by the Porcupine and Timiskaming assemblage rocks which unconformably overlie the older assemblage. Older syn-tectonic intrusions (2695–2685 Ma) may be related to the compressive stresses that induced early folding and faulting related to the onset of continental collision between the Abitibi and older sub provinces to the north. Younger syn-tectonic intrusions (2680–2670 Ma) are coeval with the Timiskaming assemblage and are spatially associated with the Porcupine Destor and Larder Lake Cadillac deformation zones. The late tectonic intrusions (2670–2660 Ma) are possibly synchronous with D4 folding within the Timiskaming assemblage rocks in the Timmins area. They represent the final stage in transpressional deformation along the Porcupine Destor deformation zone and may be correlative with the D2 event identified in the Kirkland Lake–Larder Lake area. The regional deformation zones commonly occur at assemblage boundaries and are spatially associated with long linear belts, representing the sedimentary assemblages (i.e., Porcupine and Timiskaming). It has been proposed that the regional association of the Porcupine Destor and Larder Lake Cadillac deformation zones and major assemblage boundaries are proximal to the locus of early synvolcanic extensional faults.

4.2 Property Geology

The property is underlain by northwest-trending ultramafic and mafic to intermediate metavolcanic rocks of the Pacaud Assemblage and the Catharine Group, Stoughton-Roquemaure Assemblage, to the southwest and intermediate to felsic metavolcanic rocks of the Skead Group, Blake River Assemblage to the northeast, Figure 5. Occasional ultramafic and mafic to intermediate intrusive rocks occur as stock and sills emplaced into the metavolcanic rocks. Relatively undeformed, younger alkaline to calc-alkaline felsic intrusive rocks were emplaced into the metavolcanic rocks as irregular stocks and dykes, which include the Allied, Planet, and Meilleur syenite intrusions. Lamprophyre dykes cut all other units. Felsic intrusive rocks of the Round Lake Batholith bound the metavolcanic rocks to the west. Occasional north- to northwest-trending diabase dykes cut all older units. The most prominent structures are a series of northwest-trending faults and include the Pacaud and Catharine faults. There is also a series of lesser northeast-trending faults and shears. Gold mineralization is associated with quartz+/-carbonate veining best developed in, or adjacent to, the Allied, Planet and Meilleur intrusions.

Most of the property is underlain by mafic to intermediate rocks with lesser ultramafic metavolcanic rocks. The mafic metavolcanic rocks are comprised of massive flows, pillowed flows, and lesser volcaniclastic rocks. Metamorphic grade and deformation increase towards the Round Lake Batholith to the southwest, and most of the massive flows on the property contain medium- to coarse-grained amphibole. The presence of coarse-grained amphibole suggests that it can be difficult to distinguish between coarse-grained flows and gabbro sills. The intermediate metavolcanic rocks are subordinate units occurring as occasional flows and volcaniclastic rock interbedded with the mafic metavolcanic rocks. Ultramafic metavolcanic rocks rarely outcrop and are generally intensely altered, but are thought to be spinifex textured flows.

The northeast portion of the property, northeast of the Catharine Fault, is underlain by predominantly intermediate to felsic metavolcanic rocks that are dominantly volcaniclastic with lesser flows. Occasional mafic volcaniclastic units are interbedded with the intermediate volcaniclastics closer to the Catharine Fault.

Intrusive rocks range from syn-volcanic to syn-tectonic in age with the syn-volcanic rocks being dominated by mafic to intermediate compositions and syn-tectonic rocks generally intermediate to felsic in composition. Syn-volcanic intrusions are generally medium- to coarse-grained gabbro to diorite that may form sills or composite sills tens of metres in thickness. Felsic to intermediate intrusive rocks of the Round Lake Batholith represent an early syn-tectonic igneous event. Late, syn-tectonic intrusions are dominantly medium- to coarse-grained, massive, syenite with lesser granodiorite and feldspar+/-quartz porphyritic dykes and sills. These intrusions may form large irregular stocks of predominantly syenite composition that appear to be composite of multiple intrusive phases of dyking and silling. Lamprophyre dykes are rarely exposed but are intersected by drilling, and are interpreted to be a late phase of the syn-tectonic alkaline intrusive event as they cut all older units.

5.0 EXPLORATION

In the spring of 2015, Oban flew a LIDAR and airborne magnetic survey over the Miller property. In May and June, 2015 Oban contracted Glen Mcbride to cut 37.5 km of grid. In May and June, 2015 Oban retained the services of Orix Geoscience Inc. to map the Miller property. The program consisted of mapping at 1:500 to 1:1000 in the areas between the Allied, Planet and Meilleur Syenite. The Planet Syenite trench was mapped at 1:100 and channel sampled. Based on the mapping, a 4066m drill program was completed on the property between July and September, 2015.

5.1. Plans and Permits

The 2015 work program was completed under plan PL-15-10417 and permit PR-15-10650, listed on the Environment Registry as EBR Registry Number 012-3804. This permit covers drilling on claims 4267278, 4267277, 4267276, 4267279, 4267275, 4215970, 4271892, 4275152, 4275153, 4275154, 4272892, 4272893, 4272895, located in Boston, Catharine, McElroy, and Pacaud (http://www.ebr.gov.on.ca/ERS-WEB-External/displaynoticecontent.do?noticeId=MTI0NzA0&statusId=MTg4MzEw&language=en).

5.1 Line Cutting

In May and June 2015, Oban contracted Glen McBride to cut 37.5 km of grid to encompass the Allied, Meilleur and Planet intrusions. The 2015 grid consisted of 19 lines (L0N to L18N) at 100 m spacing oriented at a 45° azimuth and a baseline (L0E) at a 315° azimuth, see Figure 6 and Appendix A: High Resolution Maps.

5.2 Geophysics: 2015 Airborne Magnetic-VLF Survey

K8aranda Geophysiques Ltd. was commissioned by Oban to fly a helicopter-borne gradient magnetic and very low frequency (VLF) survey over the entire Miller property from March 25 to April 3, 2015 (Figure 7). A total of 960.8 line kms were flown with a flight line spacing of 50 m. The average altitude of the gradiometer was approximately 40 m. Based on the average survey speed of approximately 110 km/h and a sampling frequency of 10 Hz, data samples were recorded at intervals of approximately 3 m. The instrument used was a GEM System potassium vapour, 3-sensor gradient magnetometer with sensor separations of 2.95 and 3.45 m respectively. The VLF receiver monitored Cutler Maine (24.0 kHz).

The magnetic survey highlighted the regional northwest-trending mafic to intermediate metavolcanic rocks and gabbro sills located southwest of the Catharine Fault. The intermediate metavolcanic rocks to the northeast of the Catharine Fault have a lower magnetic response, including the area around the Meilleur intrusion. The Allied and Planet intrusions have low magnetic responses compared to the surrounding mafic to intermediate metavolcanics, while the Meilleur is a relative high compared to the surrounding intermediate metavolcanics. The VLF results over the intrusions did not result in a distinctive response. A copy of the K8aranda Report is contained in *Appendix B: K8aranda Airborne Magnetic-VLF Report.*

5.3 Lidar Survey

In May 2015, Oban contracted KBM Resources Group to conduct a LIDAR and ortho-image survey over the entire Miller property. The survey was conducted using a Trimble Harrier 68i system which employs

a 400 kHz repetition rate in combination with high-quality ortho-imagery. The LIDAR survey included a 0.5 m resolution bare-earth DEM, with a full point-cloud collected at 4 points per metre. The ortho-image survey produced geotiffs with an 8 cm resolution.

The LIDAR survey was useful for identifying geological features, including lineaments and faults, and historical workings, including pits, trenches, and trails. Identification of these features aided in the planning of the 2015 field work and was also helpful in the field as a reference while mapping. A copy of the KBM Resource Report is contained in *Appendix C: Lidar Report*. *Appendix A: High Resolution Maps* contains 1:5000 maps of the DEM and Ortho-image.

5.4 2015 Mapping and Sampling

In May and June 2015, Oban contracted Orix Geoscience Inc. to perform geological mapping and sampling to identify controls on mineralization and map out the distribution of syenite intrusions on the Miller Property. George Pollock and Marc Cardinal from Northstar prospected and sampled along the 2015 gridlines to assist with the program. Tom Hart assisted with mapping and oversaw the QAQC program.

The focus of the mapping was the Allied, Planet and Meilleur intrusions which were mapped at 1:500. The areas between these intrusions were mapped at 1:1000. The historic Planet Syenite trench was mapped at 1:100 and was channel sampled. A total of 551 assay samples and 50 QAQC samples were taken during this program.

Appendix A: High Resolution Maps contains 1:1000 and 1:4500 geology maps of the property showing the outcrops, interpretation, structural measurements and grab samples. It also contains the Planet Syenite trench map at 1:40. Rock descriptions of grab and channel samples are located in *Appendix D: Assay Rock Descriptions. ALS Assay certificate*s for grab and channel samples are located in *Appendix E: ALS Assay Certificates - Grab and Channel Samples*.

5.4.1 Allied Syenite

The Allied syenite is a northwest-trending intrusive body that is approximately 280 m by 80 m hosted in massive to pillowed mafic volcanic (Figure 5). Based on the 2014 and 2015 drilling, the syenite appears to be vertical. The most prevalent syenite phase observed in mapping was the crowded porphyritic (Sy1), with rare feldspar porphyritic (Sy2) outcrops and sporadic aplite dykes. Near vertical feldspar porphyritic dykes cut the syenite of the main body as well as the adjacent mafic metavolcanic rocks, and are usually oriented parallel to the eastern and western margins of the body. The main body of the Allied intrusion is bounded to the south by two faults, an east-trending fault dipping approximately 60° south and a west-trending fault dipping approximately 75° north. It is interpreted that the west-trending, north dipping fault terminates the east-trending fault and the intrusion at depth. The main body narrows towards the northwest and mapping suggests it pinches out on surface.

Within the Allied syenite there are two sets of quartz veins, flat extensional cm-scale quartz veins and younger shear veins. These veins were not observed in outcrop, only in drill core. The Allied syenite is bounded by northwest-trending faults which were interpreted from drilling, geophysics and LIDAR data.

Mapping the Allied intrusion is difficult due to limited outcrop exposure with the majority of the intrusion in a topographic low filled with sand and swamps. Outcrops of syenite are visible at the outer contacts and the interpreted extent of the syenite was determined using outcrops, drill hole data and geophysics, as the Allied syenite forms a magnetic low. Less than 50 samples were collected from the Allied intrusion, with many of the samples being rubble from historical pits and trenches. Only seven samples returned

gold values >1.0 g/t Au. The highest gold value returned was 11.85 g/t Au in sample 29661 taken in the northwest portion of the Allied syenite and comprised of an equigranular syenite with chlorite and quartz veins. Two samples from the west side of the intrusion, 29651 and 29652, returned 2.30 g/t Au and 2.77 g/t Au respectively.

Along the eastern contact of the syenite there are 3 historic pits. This area has been heavily sampled from 2012 to 2014 therefore few samples were taken from this area during the 2015 program. The best assay taken from this area in 2015 returned 212 g/t Au and was hosted in a boulder of quartz with abundant visible gold and tellurides (Table 5). Sample 29661 was taken at the northwest portion of the Allied syenite and returned 11.85 g/t Au. This sample was hosted in equigranular syenite with chlorite and quartz veining.

East and southeast of the Allied syenite is a series of north- and east-trending trenches in mafic volcanic. The best assay from this area was sample R333701 which returned 52.5 g/t Au and was hosted in a shallow dipping 10 cm quartz vein with disseminated pyrite. Other samples is this area were taken from boulders at the edge of historic pits and returned up to 23.3 g/t Au.

5.4.2 West Allied

Two felsic dykes were identified during the 2015 mapping program in the area to the west-northwest of the Allied Intrusion. One of the dykes is a 250 by 15 m wide northwest-trending dyke, located approximately 185 m west-northwest of the Allied intrusion. The other dykes is a 130 m by 5 to 20 m wide, west-northwest-trending dyke, located approximately 400 m west of the Allied intrusion. The dykes are composed of massive, medium- to coarse-grained equigranular syenite cut by occasional aplite dykes and hosting occasional quartz veins. The veins may be bounded by a reddish potassic alteration, and host up to 2% disseminated pyrite.

Although, there was no indication that these dykes formed part of the Allied intrusion, the area was referred to as the West Allied. There were no significant anomalous gold values returned for the field samples collected on these dykes however, due to their similarity in lithologies and proximity to the Allied intrusion, two holes were collared in this area.

5.4.3 Planet Syenite

The Planet intrusion is an irregularly shaped body with surface dimensions of approximately 150 m west by 200 m north, located about 925 m north of the Allied intrusion. This intrusion is predominately equigranular syenite (Sy1) with sporadic aplite dykes. The Planet syenite contains visible quartz grains therefore it is more likely a quartz syenite.

The historic trench in the Planet intrusion was hand stripped at the beginning of the program to better understand the geology and mineralization. The stripped area was mapped at 1:100 by Ali Ghorbani, Justin Bernard, Michaela Kuuskman and Thomas Hart. A channel sampling program was designed by Thomas Hart and Michaela Kuuskman to test the mineralization potential of the various vein sets observed during the mapping of the stripped area. The channels were cut by Glenn McBride Exploration Services under the supervision of the Tom Hart.

The following observations are based on the 1:100 mapping of the Planet Syenite trench. A high intensity of stockwork quartz veining is observed in the Planet Syenite stripped outcrop with 3 oblique to orthogonal vein sets. Their widths range from less than 1 cm to over 15 cm. The primary vein set is northwest-trending steeply dipping veins. There are also north-northwest-trending veins that are vertical to steeply dipping. This vein set is concentrated at the western portion of the Plant Syenite trench where strong stockwork structure has formed. There is also a set of west-southwest-trending veins that dip between 25° and 40° to the northwest. Based on cross-cutting relations, the west-southwest-trending veins seem to be the youngest, however crosscutting northwest veins conflict this observation.

A total of 84 channel samples were taken, with 2 samples returning over 1 g/t Au, see Table 6. Sample R333565 returned 1.645 g/t Au from a 0.75 m long channel comprised of massive syenite with two 1 mm vertical quartz veins and one shallow 3 mm quartz vein, hosting trace to 1% fine-grained pyrite. Sample

R333575 returned 1.19 g/t Au from a 0.65 m long channel consisting of massive syenite with trace to 1% disseminated pyrite and two 1 cm shallow quartz veins. The common feature between the two samples is a pink alteration halo to shallowly north dipping veins with up to 1% pyrite. There are similar shallowly north dipping veins with alteration haloes in other samples that did not return anomalous gold values, however based on the more detailed work completed in the Miller intrusion, it is interpreted that all of the shallowly dipping veins are of the same generation and the difference in assay results is a result of a nugget effect as observed elsewhere on the property.

Immediately north of the Planet syenite, there is a narrow-linear zone of moderate to strong east-northeast-trending foliation, striking between 050° and 070° dipping between 50° and 60° to the southeast. This area is approximately 400 m long and locally up to 30 m wide. This zone is associated with iron-carbonate alteration and disseminated pyrite. Samples from this area returned up to 4.3 g/t Au.

5.4.4 Meilleur Syenite

The Meilleur intrusion is an irregularly shaped, dyke-like body with surface dimensions of approximately 110 m west by 650 m north, located about 1,500 m north of the Allied intrusion and 800 m northeast of the Planet. Located north of the Catharine Fault, the Meilleur intrusion is hosted by intermediate metavolcanic rocks of the Skead Group in contrast to the mafic metavolcanic rocks of the Catharine

Group that host the other two intrusions. The intrusion is composed of a massive, red to pink equigranular syenite cut by white quartz veins up to 10 cm wide, with a variety of orientations. The Meilleur syenite is bounded by two north-northwest-trending shear zones interpreted based on LiDAR and geophysics. There are two vein sets in the intrusion, a northeast-trending shallowly dipping set and a northeast-trending vertical set. The primary vein set is the northeast-trending, 25° northwest dipping set. Both vein sets host 0.5% to 1% molybdenite, pyrite and occasional tourmaline.

Mapping in the area of the Meilleur suggests that the intrusion is approximately 60m wider than outlined by previous mapping. This interpretation is supported by three holes completed in 1996 which intersected syenite in an area of limited outcrop. Mapping indicated that the intrusion extended further north than previously shown by about 85m but overall the current interpretation is a similar dyke-like body

A total of 28 samples were collected in and around the Meilleur intrusion, and most of the samples returned less than 1 g/t Au. Three of the four samples that returned >1.0 g/t Au were located in the northern portion of the intrusion (Figure 5, Table 7). Sample R333455 returned 1.135 g/t Au and is located in a 140 m by 30 m northeast-trending syenite dyke parallel to the Meilleur syenite which had not been previously mapped.

5.4.5 Structure

There are two major fault / shear orientations on the Miller Property, northwest and northeast, with a minor north-trending set. The following description of these structures is based on an internal company report by Ghorbani (2015).

The northwest-trending faults and shears are parallel to subparallel to the strike of the lithologic units with the Catharine fault zone (CFZ) representing the most prominent structure in this orientation. The northwest faults trend 310-320^{o}, dipping steeply, and have a dextral sense of shearing with compression along the trend of the faults. The CFZ was traced for approximately 2.3 km mafic metavolcanic rocks to the southwest from gabbro sills to the northeast. A 50 m intense deformation zone along the CFZ is related to alteration, including oxidation and bleaching, and an associated magnetic low aiding in tracing the CFZ. The CFZ bounds the northeast side of the Planet intrusion, and a parallel northwest structure bounds the northeast side of the Allied intrusion.

A series of less prominent northeast-trending fault and shears are oriented 050-070^{o}, dipping 50-60^{o} SE or northwest, with a reverse sinistral shear sense, at least partially, based on the shear sense indicators associated with quartz veins with a similar geometry. A structure with this orientation was traced for 400 m along strike in a zone up to 30 m wide along the north side of the Planet intrusion. This structure had minor associated iron carbonate alteration, quartz-iron carbonate veining and disseminate pyrite. A structure with a similar orientation appears to border the south side of the Allied intrusion.

Based on the close spatial distribution of Allied, Planet and Meilleur stocks to northwest-trending

faults/shear zones combined with the observed vein geometry, it is likely that these intrusions are syn-tectonic in nature and probably emplaced during the dextral-compressional movement of either the CFZ or parallel to subparallel zones. However, further work is required to confirm this interpretation, and could include detailed chronological, geochemical, and petrological studies.

5.4.6 Veins

There are three categories of veins identified on the property, laminated fault-fill, extensional veins and vein arrays, and stockwork / fault breccia. Nearly all three of these vein categories are observed along, within, or at the dilatational jogs formed along the CFZ, likely as a result of dextral shearing.

Laminated fault-fill veins are northwest-trending, steeply dipping, low angle to parallel to foliation, forming in shear zones or faults. Southeast of the Allied intrusion, northwest-trending, steeply dipping faults/fractures host a set of mineralized fault-fill laminated quartz veins. Pinch-swell and boudinage are common accompanying these veins which may be explained by a stretching along the vein's strike/foliation and perpendicular to the compressional axis.

Extensional veins and vein arrays are northeast- to east-trending, shallow dipping, at high angles to the foliation, and form both within and outside of the shear zones. The extensional veins include the planar shallowly dipping veins formed at a moderate angle to shear zones in both intrusion stocks and volcanic country rocks, as well as arrays of planar to sigmoidal veins at high angle to the foliation generally are found within the shear zones. Mineralized, northeast-trending, extensional veins are present in all three intrusions. In the Planet, these veins dip 25-40^{o} to the northwest, in the Meilleur similar veins have even shallower dips, and in the Allied intrusion, drill holes intersected arrays of planar, shallowly dipping extensional veins. In all three intrusions, these veins are bounded by steeply dipping shear zones. It is possible that these mineralized extensional veins formed as a result of emplacement of the intrusions in dilatational zones, and the continued deformation, along the CFZ. Mineralized quartz-carbonate extensional vein are observed in the western portion of the property associated with reverse sinistral faulting which has 25 degrees dip north and may also include the No.1 Vein of the Miller Independence Mine located south of the Allied intrusion.

The third set of veins contain brittle stockwork and fault breccia observed at both the Planet and Allied intrusions. A high intensity of stockwork quartz veining is observed in the Planet intrusion associated with three oblique to orthogonal vein sets. Vein width ranges from less than 1 cm to more than 15 cm and consist, in order of importance, of the northwest-trending steeply dipping, the north-northwest-trending vertical to steeply dipping, and the east-northeast-trending, northwest dipping (25-40^{o}) extensional veins. The north-northwest veins are mostly located to the west within the strong stockwork structure. Although, in most cases, the northeast-trending shallowly dipping veins appear to be late, there are still some conflicting crosscutting relationships as sometimes they are cut by northwest-trending veins. An example of a fault breccia vein is located in the shear bounding the east side of the Allied intrusion which contains quartz veins and angular wall rock clasts with the geometry parallel to host structure.

6.0 DRILLING

In July to August 2015, Oban contracted Forthright Drilling, based out of Timiskaming Shores, ON, to complete twelve NQ diamond drill holes on the Allied, West Allied, Meilleur and Planet intrusions (Table 8, Figure 8), totalling 4,066.8 m. The rig and equipment sloop were moved between drill sites by a skidder. The drill sites are accessible by truck along a network of bush roads. The core was logged by Justin Bernard and Michaela Kuuskman, GIT both Orix Geoscience Inc. employees at the time of the drill program. The project was overseen by G. Wober, P.Geo.

The diamond drill program was designed to test the extent of the Allied syenite due to the limited outcropping and test the continuity of the mineralization intersected by Northstar in the 2014 drill program. The drill holes in the Allied syenite were spaced on 100 m sections and were drilled with an azimuth of either 065° or 245° to intersect the structures interpreted to control the auriferous veins at an optimal angle. This drilling pattern produced 4 sections through the Allied syenite.

For the West Allied, Planet and Meilleur Syenites, the drill program was planned to test the character and distribution of the gold mineralization with depth and determine the size of these intrusions. The West Allied has no recorded historical drilling. The Meilleur and Planet have been sparsely drill tested with 3 holes and 6 holes respectively. The drill holes were planned to intersect the mineralized quartz veins and structures at an optimal angle based on the results of the 2015 field mapping program

The azimuth and inclination of all drill holes were measured using a Reflex multi-shot down hole survey instrument. Measurements were made 15 m below casing, at 50 m and at subsequent 50 m intervals. The Reflex survey data is summarized in the header section on each of the drill hole logs.

The location of each drill hole was recorded by an averaged GPS reading. Based on this control, accuracy of hole positioning is estimated to be less than 5 meters. All coordinates are in Universal Transverse Mercator (UTM) projection using the North American Datum (NAD) 83 in Zone 17.

Of the 4,066 m drilled, 183.7 m of core was not sampled. The unsampled intervals were in MG15-21 and MG15-24. MG15-21 which failed to intersect the Allied Syenite therefore the majority of the hole was hosted in slightly altered to unaltered mafic volcanic. It was decided that unaltered mafic volcanic with no mineralization or veining would not be sampled. MG15-24 was planned to be drilled to a depth of 370 m to intersect a mineralized quartz vein observed on surface. This vein was not intersected in the drill hole, and of the 140 m of mafic volcanic only intervals with alteration, mineralization or quartz veining, were sampled.

A total of 3,359 samples were analysed for gold by fire assay with an atomic absorption spectroscopy finish completed by ALS-Chemex. All samples were also analyzed by a multi-element ICP-aqua regia digestion package which included Te, Ag, Cu, Ni, Pb and Zn. Information concerning the lithology, structure, alteration and mineralization was logged and entered into an excel spreadsheet. All intervals of core were digitally photographed.

Diamond drill logs are located in *Appendix F: Diamond Drill Log*. *Appendix G: Diamond Drillhole Plan Map and Sections* contains a plan map of the 2015 drill program as well as drill sections at 1:500. The ALS assay certificates for the drill program are located in *Appendix H: ALS Assay Certificate – Drillcore*.

6.1. Discussion of Results

Of the 12 holes drilled, all holes except for MG15-22 and MG15-23 returned assays above 1 g/t, *see* Table 9. The drill program was successful in testing the gold mineralization in the Allied, Planet, and Meilleur intrusions and indicates that there is little chance of gold mineralization within the West Allied intrusion.

6.1.1. Allied Syenite

The 5 holes drilled into the Allied intrusion intersected a series of quartz veins. As noted by Arteaga (2015). gold mineralization is associated with two generations of quartz veining that are irregularly distributed within the main portion of the 90 m by 280 m intrusion. The first generation of veins is centimetre-scale, milky white quartz usually with shallow dips. The second generation of quartz veins is younger and occur as pseudo-stockworks of discontinuous veinlets intersecting at 90°. These veins also display a greater variation in thickness than the first set and it is common to find veinlets 5 cm or thicker. Gold mineralization is sporadic, with the majority of the high grade intervals hosted in the shallowly dipping first generation quartz veins, hosting tellurides and rare visible gold. The distribution of gold within the veins appears to be erratic as comparable zones of 4 to 5 veins per meter may vary from approximately 1 ppm to tens - hundreds of ppb Au.

Within the 5 holes that intersected the main body of the intrusion there were 23 intervals that returned >1.0 g/t Au, with the best interval intersected in MG15-20 which returned 40.5 g/t Au over 1.0 m from 311.85 to 312.85 m included in a graded interval of 14.1 g/t Au over 3.05 m from 311.85 to 314.9 m (Table 9, Figure 8). Drilling from the southwest side of the intrusion towards MG15-20, M15-18 intersected 4.2 g/t Au over 3.0 m from 374.75 to 376.25m including 5.96 g/t Au over 0.75 m and 6.27 g/t Au over 0.75 m (Table 9).

One hole, MG15-21, was drilled south of the Allied intrusion to test the potential for a south dip to the intrusion or a structural offset to depth across the west-trending fault, bounding the south side of the intrusion. This hole also tested the southeast extension of the mineralization observed on surface and in other holes along the east side of the intrusion. MG15-21 failed to intersect the Allied intrusion, however mafic metavolcanics cut by gabbro sills, feldspar porphyry dykes and a diabase dyke were intersected. One sample returned an anomalous value of 1.08 g/t Au between 166.5 and 167.77, hosted by a zone of

carbonate-sericite-silica bleached mafic metavolcanic containing minor pyrite. The current interpretation based on the mapping and drill data has three intersecting faults terminating the Allied intrusion to the south.

6.1.2. West Allied

Two holes were collared in the area referred to as the West Allied intrusion (MG15-22 and MG15-23). Drill hole MG15-22 intersected a medium to coarse-grained syenite between 88.1 and 115.27 m that was cut by a 2.3 m wide diabase dyke. Quartz veins with pyrite, chalcopyrite, and tellurides are hosted by the syenite, however none of the syenite or the remainder of the hole samples, returned significant gold values. Hole MG15-22 was collared about 150 m southwest of MG15-23 along the same section to test a separate syenite dyke. This hole intersected medium to coarse-grained, porphyritic syenite between 148.5 and 175.15 m hosting approximately 1 to 2 quartz veins per metre, however none of the samples in the syenite, or the remainder of the hole, returned anomalous gold values.

6.1.3. Planet

Two holes were drilled into the Planet intrusion with MG15-24 collared near the northeast contact and MG15-25 collared approximately 110 m east of MG15-24 and was drilled to be parallel to MG15-24. MG15-24 intersected a series of five syenite dykes between 45.45 and 229.47 m which range from 2.5 to 57.2 m in width and are separated by fine-grained mafic metavolcanic rocks. The syenite and metavolcanic rocks host numerous centimetre-scale quartz veins containing pyrite with lesser chalcopyrite, molybdenite, and rare visible gold. A total of 16 samples returned greater than 1 g/t Au, with the best interval returning 74.9 g/t Au from 53.7 to 54 m in a 5 cm quartz vein containing coarse tellurides and 5 specks of visible gold (Table 9). MG15-25 intersected medium-grained, equigranular syenite between 39.7 and 284.48 m that hosted numerous centimetre-scale quartz veins containing pyrite with lesser molybdenite, and rare visible gold. The best interval returned 4.7 g/t Au from 242.2 to 243.5m and was hosted in potassic altered syenite. The 4 cm vein at 83.13 m containing a speck of visible gold did not return an anomalous assay result. It was noted that this hole intersected less quartz veining and alteration than MG15-24.

6.1.4. Meilleur

Two holes were collared to intersect the north end of the Meilleur intrusion (MG15-26 and MG15-27). MG15-26 intersected a red, medium-grained syenite between 89.64 and 316.06 m with a satellite dyke between 332.06 and 335.73 m. The syenite hosts centimetre- to a few tens of centimetre-scale quartz veins containing pyrite and 0.5 to 1% molybdenite. The best assay returned 20.8 g/t Au from 86.55 to 87.5 m in a faulted bleached mafic metavolcanic. There were 13 intervals hosted by syenite that returned >1.0 g/t Au (Table 9) with the best interval returning 14.3 g/t Au from 293.8 to 295.2m in faulted syenite with moderate chlorite alteration. MG15-27 was collared approximately 85 m southwest of MG15-26 with a parallel orientation and intersected a medium-grained syenite interpreted to be a satellite dyke between 9.0 and 46.6 m with the main body occurring between 101.94 and 366.0 m, which hosts numerous quartz veins up to 14 cm in width containing pyrite and trace to 2% molybdenite. Three intervals returned >1.0 g/t Au with the best interval returning 10.2 g/t Au from 295 to 296 m.

6.2. Core Logging and Sampling

The drill core was logged and photographed, four boxes at a time. The logs recorded the different lithologies, alteration types, mineralization, position and orientations of veins, fractures, RQD and other structures. This information was recorded in a password protected Excel spreadsheet.

The sampling protocol was based on representative sample widths of the mineralogy, lithology, vein, structure, or alteration zone within the limits of a maximum sample length of 1.5 m and a minimum sample length of 0.3 m. Samples did not cross lithological contacts, changes in structural style, veins/vein sets, or strong alteration zones, unless the lithology, structure, vein or alteration was less than 0.3 m in width, and then only to meet the 0.3 m minimum.

A removable portion of the sample tag was stapled into the core box at the beginning of the sample interval. The core cutter removed half the tag and placed into a sample bag inscribed with that number. The beginning and end of each sample interval was marked on the core with a china marker. The core was sawn in half with a core saw using a diamond blade with half of the core placed into a numbered bag with the sample tag, and the remaining half of the core was placed in the core box. Sample numbers and corresponding intervals were recorded in the sample book and a password protected Excel spreadsheet.

For all field geochemical samples collected, a sample description and the site location, obtained from a handheld GPS, were noted on a pre-numbered sampling booklet. Sample descriptions include lithology, structural measurements, mineralization and alteration. The sampling site was flagged and clearly marked in the field with the sample number for eventual future visits.

7.0 SAMPLE PREPARATION AND ANALYSES

All rock and core samples from the 2015 field and diamond drilling program were submitted to ALS Minerals for analyses. Samples were prepared using PREP-33D method and analyzed using the AU-ICP22 and ME-MS41 methods. If a sample assayed >10 g/t Au, then the pulp was re-assayed using gravimetric finish method, AU-GRA22, as well as Screen Metallics Gold Method, AU-SCR-21. The screen metallic analyses were then considered to be the final gold value. The following descriptions were supplied by ALS-Chemex.

9.0 CONCLUSIONS AND RECOMMENDATIONS

The geology of the Miller Property appears favourable for hosting additional and potentially economical deposits of gold in a manner consistent to those deposits associated with other gold camps in the Abitibi (Matachewan, Kirkland Lake, Larder Lake, Val d'Or). It is recommended that additional work to further assess the economic characteristics of the gold mineralization should include an integrated property scale exploration program to examine the relationship between the syenite intrusions, metavolcanic rocks, quartz veins and structures and evaluate their potential to host additional deposits of gold.

A program of trenching and channel sampling should be completed on the Allied, Planet and Meilleur intrusions to better expose the intrusions and auriferous quartz veins. This program should include locations within the intrusions and across the regional structures that host gold mineralization, including the northwest-trending zone along the east side of the Allied intrusion and the northeast-trending zone along the north side of the Planet intrusion, to better assess the relationship between the intrusions and the structures which appear to control the auriferous quartz veins. This trenching and channel sampling program should also examine the mineralized quartz veins located to the south of the Allied intrusion hosted by a set of structures associated with those in the intrusions.

A detail structural study should also be completed targeting the veins and regional structures that appear to have some control on the emplacement of the veins. This study would overlap with the trenching program but should also examine other areas on the property. A better understanding of the structures should aid in developing a better understanding of the relationship between the auriferous veins that are syenite-hosted and metavolcanic-hosted veins.

A diamond drilling program is proposed to follow-up on the results of the trenching program and structural study to further develop an understanding of the controls on gold mineralization which will add in further determining the potential for economic gold mineralization on the Miller Property. The number and location of drill holes is dependent on the results of the field programs and may include holes in the area of the Planet, Meilleur, and Allied intrusions, as well as drilling in the area of the No.1 and Independence veins.

1.0 Executive Summary

K8aranada Geophsyiques Ltd. was commissioned by Oban Mining Corp. to fly a helicopter-borne gradient magnetic survey over the Miller property in the Kirkland Lake, Ontario area. The survey conducted over the Oban claims was an extension of a previous survey to the south in December 2014. The extensions of the Cote claims were also covered at 50m line spacing. The survey was flown between the dates of March 25 – April 3, 2015 and covered of a total of 1,243.5 line-kilometers (282.7 line-kilometers over property claim boundary).

The system that was flown over the Miller property consisted of four (4) GEM System potassium vapour, magnetometers mounted on a customized platform with a 2.9 m vertical separation and a 10 m horizontal separation. This platform was designed by K8aranada geophysics and named the “White Eagle”. This system is capable of measuring both vertical and cross-line magnetic gradients with the in-line gradient being calculated using a time lag offset that simulated a sensor separation of ~3m.

As an added benefit, a Very Low Frequency (VLF) electromagnetic receiver was installed on the White Eagle. A VLF station in Cutler, Maine (24.0 kHz), the strongest available signal in the area, was used for total field, in-phase and quadrature measurements.

Navigation of the aircraft was achieved using differential positional (DGPS) and aided by both radar and laser altimeters for high precision topographic draping. All ancillary equipment was mounted directly to the magnetometer for higher accuracy measurements.

The survey was flown using the WGS-84 Datum and re-projected into the UTM coordinate system (Zone 17) during post-processing. All data processing, quality control, databasing and map products were performed in Geosoft Oasis Montaj V8.2.

Described in this report are the following sections: Property Description in Section 2.0, Survey Procedures in Section 3.0, Personnel in Section 4.0, Equipment in Section 5.0, Processing in Section 6.0, Results in Section 7.0, Deliverables in Section 8.0, Interpretation in Section 9.0 and Conclusions & recommendations in sections 10.0 & 11.0.

Appendix A contains a statement of qualification of the Author.

Appendix B contains a list of the survey outline points in NAD-83, Zone 17 N.

2.0 Property Description

Oban & Miller

The Oban and Miller properties are located approximately 25 km Southeast of Kirkland Lake, Ontario and 125 km East-Southeast of Timmins, Ontario (Figure 1). The property covers ~59 square kilometers and is defined by relatively flat topography ranging from 209 to 338 metres above sea level. Access to the site is possible via Hwy 624 which runs north-south through the East side of the property. The crew staged out of Kirkland Lake, Ontario. The property was flown at 100m line spacing in a NE-SW direction with 500m, NW-SE tie lines (See Figure 2). The property covers a number of contiguous mineral claims as shown in Figure 3.

Additional survey coverage details can be found in Table 1.

3.0 Survey Procedures

Prior to survey execution, planning of the flight lines was conducted on each area according prescribed specification. Navigation files were developed in proprietary planning software based on provided boundary files for each survey area. The software exported formatted files that were imported into the onboard navigation system use by the pilot and operator during survey. Typically, tie lines are flown first followed by survey lines in a sequential order. Any reflights determined by the quality control geophysicist were reflown immediately and integrated into the master database.

After each flight, the data was exported from the field computer, processed and checked for quality control issues. This procedure was completed at the end of each survey day in order to notify the helicopter operate of any concerns or flights prior to the next survey day.

All accepted data was imported into Geosoft for further processing and trimming. The database survey line path was trimmed to the property boundary plus 100m. Total line km's calculated for the survey (as shown in Table 1) were based on a flush boundary and the additional 100m provided as an added benefit.

During survey, the average altitude of the gradiometer was ~ 40 m. The height for the towed system was closely monitored with the use of a laser altimeter. Best effort is made to ensure close contouring to the regional topography, however, certain obstructions such as tall trees or steep topography may required higher flight altitudes due to safety concerns. Based on an average survey speed of ~110 km/h and a sampling frequency of 10 Hz, data samples were recorded at intervals of approximately 3 m.

All ancillary equipment used to guide navigation (laser altimeter, radar altimeter and GPS) were all mounted directly on the gradiometer in order to calculate precise location and position with minimal geometric error.

4.0 Personnel

The field crew engaged on this project was composed of four (4) personnel for the start of the project including the pilot, equipment operator, technical support and geophysicist. The pilot was responsible for following the pre-planned flight path and maintaining a steady altitude of the geophysical system at all

times. An operator accompanied the pilot in the helicopter to ensure all geophysical sensors were operating as expected and watching for data quality issues.

At the end of each flight or survey day, the data files were sent to the geophysicist for processing and analysis. Any data quality issues not addressed during flight were caught during the processing stage and re-flights recommended for the next survey day. Following the completion of each survey area, a preliminary database was generated and sent for review. All final products including Geosoft databases, grid products, maps, reporting and interpretation were performed by the project geophysicist.

Table 2 provides a listing of all personnel involved in the project, their employers, respective positions and a brief description of their responsibilities throughout the project.

5.0 Equipment

5.1 The Helicopter

Heli Explore, based out of Lasarre Quebec, were commissioned by K8aranda Geophysique to tow the geophysical equipment throughout the project. The helicopter used was a Eurocopter AStar 350 BA with registration C-GWMO as shown in Figure 4. The AStar B2 helicopter is capable of towing geophysical equipment in challenging topography at a wide range of temperatures. On a full tank of fuel, an AStar BA is capable of 3 hours of continuous flying with the current payload. Navigation of the helicopter was accomplished using differential GPS and high precision altimeters.

Figure 4 - The survey was flown with a Eurocopter AStar BA (*photo from www.heliexplore.ca*)

5.2 The Gradiometer

The equipment used on this project was a 4-sensor potassium magnetic gradiometer designed by K8aranda Geophysique Ltd. The gradiometer system was attached to the helicopter by a 100 ft long tow cable. The tow cable is designed to hold the weight of the system and integrates a shear pin as a weak link. Cables for the magnetic and laser altimeter data follow the tow cable to the helicopter.

The gradiometer is constructed with a fiberglass shell with pods design to house each magnetic sensor. The pods each contain an adjustable gimble and removable covers for easy access and realignment. In total, the gradiometer contains four (4) sensors mounted within the Y-Z plane at the front of the frame: one (1) located at the top of the frame, 1 at the base of the frame and two (2) on the outer edges of the frame (see Figure 5). The center, bottom sensor is used for the total magnetic intensity measurement and combined with the top sensor at ~2.9 m away for the measured vertical gradient. The two outside sensors are separated by 10 metres and used for the cross-line gradient measurement. The length of the bird is ~7 metres and weighs approximately ~180 kg. The bird can be disassembled into multiple components for ease of transport.

This gradiometer is uniquely designed to keep a large separation between the equipment electronics and the magnetic sensors. This allows for cleaner data collection unaffected by electronic noise. By design, the sensor positions allow for the measurement of the cross-line (difference between bottom sensors) and the vertical (distance between the top and bottom sensors) gradients. The inline gradient is calculated by applying the same difference formula to 2 consecutive records that occur approximately 3 metres from each other.

The gradiometer data is collected at a rate of 10 samples per second (10Hz) and merged with all ancillary data. The combined data stream (including mag, gps, vlf and radar information) is then sent up the tow cable to the data acquisition system in the helicopter. Specifications for the magnetometer sensors are given in Table 3.

5.3 The VLF-EM System

Located within the magnetic gradiometer were two (2) VLF (very low frequency) EM receivers that can be tuned to any of the operational VLF transmitters worldwide. Typically, two orthogonal stations are chosen based on proximity and include Cutler Maine (24.0 kHz), La Moure (25.2 kHz) and Jim Creek Seattle (24.8 kHz). For this survey, both 25.2 kHz and 24.0 kHz frequencies were recorded with the latter producing the highest quality data.

Measurements of the in-phase, quadrature-phase and total field were taken at a 10 Hz sample rate. The in-phase measurement is easily affected by variations in the sensor orientation and may not be useful in areas of rugged topography or where bird movement is significant. The resulting signal measured by the sensors can reveal weak conductors that are energized by the strong VLF signals.

5.4 The Magnetometer Base Station

In order to remove fluctuations in the Earth's magnetic field (diurnal), two redundant base stations were setup daily to record the Earth's field at fixed position in an area with no external interference. Redundant stations are preferred in the event one fails during a survey day. Each base station included a spare potassium sensor (same sensors as used in the gradiometer) connected to a dedicated laptop. Each setup was powered by two 12V batteries with enough power to easily last a full day. The magnetic data

readings were logged in communications software and synchronized to UTC time for direct correlation with survey data. Base station data was collected at a rate of 10 Hz.

5.5 Altimeter

Two altimeters were used during the survey in order to monitor and collect altitude data of the magnetic gradiometer. Both altimeters were mounted directly to the belly of the gradiometer structure for the most accurate measurements. The primary altimeter was mounted in the nose of the gradiometer, a Multiwave Sensors laser altimeter, and was used for navigation and was capable of seeing both topography and vegetation elevations. Laser altimeter data was recorded as the magnetometers exact height above ground and was used to generate the Digital Terrain Model (DTM) product. A second altimeter, a Free Flight TRA 3500 radar altimeter, was monitored for topographic detailing and as a redundancy to the laser altimeter.

5.6 Navigation

Flight path navigation was achieved using a Novatel V4.0 GPS receiver (WAAS enabled) which connected directly to proprietary navigation software called Maglog from Geometrics. Prior to survey commencement, navigation files were generated for each survey area and imported into the Maglog software providing an easy to follow plan view of all survey lines.

6.0 Processing

Data processing was achieving within Geosoft's Oasis Montaj through the use of several custom scripts and a concise data quality control plan. The methods used during this survey are detailed below.

6.1 Base Maps

Base maps used in this project were generated using Geosoft control files. General map layers include, data view, inset map, specifications and legends. The data view of all base maps was surrounded by coordinate reference points in both UTM NAD83 and Lat / Long positions. Within the data layer, GIS layers such as lakes, rivers, roads and topography have been imported from Geogratis servers. Mineral license boundaries have also been imported from provincial datasets. Survey data such as block boundaries, flight path, geophysical grids and contour lines are overlaid on top of all base layers.

Topographic shading has been derived from 90 m resolution digital elevation model (DEM) data provided by the NASA Shuttle Radar Topography Mission (SRTM) and shaded at an inclination and declination of 45º.

6.2 Flight Path

The geophysical survey flight path is merged with the incoming magnetic data string at the same sampling rate of 10 hz. No additional interpolation is required on the flight path data. All lines have been trimmed to a boundary 100m outside of the required boundary providing a small amount of additional data. A low pass filter is applied to the flight path prior to finalization.

6.3 Terrain Clearance

The digital terrain model (DTM) was derived by subtracting the laser altimeter value (located on the magnetic gradiometer) from the GPS measured elevation (mean point above sea level). The DTM grids were microleveled and re-sampled into the database to remove line to line banding cause by slight pitch changes in the magnetic bird based on flight direction. The DTM values are to be considered relative as they have not been tied into any surveyed geodetic point.

6.4 Magnetic Data Processing

In ideal conditions, all tree magnetic data sensors will record clean data that roughly follow one another. In some situation, dramatic swings in the magnetometer can cause one or more of these sensors to

become unlocked. The process of re-locking is generally fairly quick and only results in a dropout that is less than 3-4 seconds. In these situations, the dropped magnetic data is deleted from the data and replaced with “dummy” values. A quality control channel gave an indication if the sensor has lost lock. Loss of lock is rare within survey lines (unless in rough terrain) and typically only occurs on turn-arounds. In the event of excessive dropouts, the magnetic sensors will be adjusted to a new azimuth and dip to better couple with the Earth’s magnetic field.

A secondary magnetic recording station was setup near the base location which remains stationary and clear of electromagnetic interference and ferrous objects. The base magnetometer continually collects data at a rate of 10 Hz during all survey operations. This data represents the diurnal and is later subtracted from the acquired airborne magnetic data during preliminary processing. This procedure is only performed on the Total Magnetic Intensity product as it is not required for the gradient calculations.

As the horizontal gradients are dependent on line direction, positive polarity is defined as to the north and east. On south and west direction lines, the horizontal gradients are multiplied by -1.

The magnetic data from the individual sensors as well as the computed total magnetic intensity have no filtering applied. The computed gradients are lightly filtered to remove high frequency noise common in areas of rough terrain or flying conditions. The magnetic data grids were tie line-leveled and the resulting grids micro-leveled.

6.4.1 Magnetic Analytic Signal

The magnetic analytic signal (ASIG) is calculated by taking the square root of the sum of the squares of each of the 3 axis components of the gridding total magnetic intensity data. The equation for the analytic signal is:

$$\mathrm{ASIG} = \sqrt{\left[\left(\frac{\mathrm{dT}}{\mathrm{dx}}\right)^2 + \left(\frac{\mathrm{dT}}{\mathrm{dy}}\right)^2 + \left(\frac{\mathrm{dT}}{\mathrm{dz}}\right)^2\right]}$$

where dT/dx is the in-line gradient, dT/dy is the cross-line gradient and dT/dz is the vertical gradient of the total magnetic field.

In general, the analytic signal is a gradient product that ignores the effects of target orientation. This "turns" all responses, regardless of how they interact with the earth's magnetic field, into the positive direction. Therefore, both negative anomalies & dipole effects will appear positive centered of the target source.

The analytic signal can be used to map the edge of large magnetic bodies as well as bring to light anomalous trends that can appear insignificant in a TMI grid. The nature of the algorithm also strips out effects of deep regional responses and focuses more on the near surface.

6.4.2 Magnetic Tilt Derivative

The magnetic tilt derivative (TDR) combines all three gradients (X, Y and Z) to produce what is a called a tilt angle. This product highlights very subtle, near surface structures in the dataset where the zero contour line of the grid is said to represent geology contacts or edges of bodies.

The magnetic tilt derivative is calculated by the following equation:

$$\mathrm{TDR} = \tan^{-1}\left[\frac{{}^{\mathrm{dT}}/_{\mathrm{dz}}}{\sqrt{\left({}^{\mathrm{dT}}/_{\mathrm{dx}}{}^{2} + {}^{\mathrm{dT}}/_{\mathrm{dy}}{}^{2}\right)}}\right]$$

where dT/dx is the in-line gradient, dT/dy is the cross-line gradient and dT/dz is the vertical gradient of the total magnetic field.

6.5 VLF-EM Data Processing

The measured VLF components were converted into a digital signal and then appended to the data string in the main magnetometer console. This entire data string is then transmitted up the tow cable to the data acquisition system in the helicopter. Processing of the VLF data included:

- Polarity reversal of alternating quadrature-phase measurements based on line direction;
- Removal or erroneous data points; and
- Grid Microleveling for filtering line-by-line variations.

7.0 Results

The following images are shown in the corresponding figures. Each image has been color shaded with a sun angle of 45° inclination and a declination parallel to the line direction in order to enhance regions of high gradient. All grid products are processed independently and lightly micro leveled for the final product.

9.0 Interpretation

K8aranda has acquired high resolution magnetic gradiometer data over the Miller property in the Kirkland Lake, Ontario area. Below is an interpretation of the results over each survey area with a focus on structure.

9.1 Magnetics

The individual magnetic products have been referenced in order to better define the numerous structures throughout the area. The various gradient and derivative products fully represent the components of the magnetic field and can provide specific information not obvious in the total field data. The in-line magnetic gradient (IGRAD) emphasizes subtle magnetic features perpendicular to the line direction, the cross-line gradient enhances features parallel to the flight path and vertical gradient product (VGRAD) emphasizes all subtle features in the data. In addition, the magnetic analytic signal (ASIG) is produced by calculating the vector sum of all three magnetic gradients to produce a grid that is independent of the effect of orientation from subsurface bodies. Typically, the orientation of a magnetic target can produce a positive or negative response in the total magnetic field relative to its orientation. The ASIG produces highs directly over magnetic sources that are independent of the direction of the earth's magnetization vector.

The magnetic data collected over the Miller survey area is complex, similar to and an extension of the data collected in 2014 on claims to the south. Much of the area is characterized by heavy, magnetic bands suggesting geologic layering with possible outcropping (see Figure 16). These features are likely the result of meta-sedimentary units that contain magnetite iron formation (MIF) because MIF is so obvious in the magnetic data. Priority should be given to areas within the MIF where folding is observed as sulphide carrying gold is often concentrated along fold noses. Structures that intersect the MIF can remobilize precious metals (such as silver or gold) found in low concentrations within the iron formation out into the country rock in higher (possibly economic) concentrations. Intrusions can also act as a heat source for the creation of syenite dikes and quartz veins, the latter carrying gold, the former a possible indicator of strike direction and extent.

To the northwest, this MIF unit cuts off abruptly and levels off in magnetic field intensity. Features within this units are very subtle and may indicate numerous fractures extending throughout the area. In general, broad, low gradient features likely represent deeper seated bodies, whereas the sharp and high gradient responses are more likely to be related to near surface features.

9.2 VLF

Airborne VLF (very low frequency) surveys have been used in the past for geological mapping in areas where the targets are only weakly conductive. This method uses military communication antenna as the primary electromagnetic field. Synchronization to this field is provided by detecting the electric field. Variations with respect to this field are provided by an orthogonal receiver coil which measures the in-phase, quadrature-phase and total field component of the magnetic field. This is done for two separate frequencies that are tuned to the transmitting frequency of the communication antenna (these values

are preset and the two strongest primary fields are selected in software). As VLF-EM transmitters do not transmit a constant amplitude source field, without a base station receiver it is not possible to quantitatively use the VLF profiles.

Normally the measurement of the in-phase and quadrature-phase signals provides for an estimate of conductance by the ratio of the two components. Weakly conductive targets produce only a quadrature response, moderately conductive targets have both in-phase and quadrature components and highly conductive targets are mainly in-phase.

VLF-EM surveys are also sensitive to changes in topography. This is because the EM fields are considered to be horizontal along the surface of the earth. When the surface of the earth is no longer horizontal (say along a major change in elevation) the VLF receiver is then measuring only a component of the VLF field. When the bird is measuring on the close side of an elevation change (the close side being the side of the hill which is closest to the transmitting station) the amplitude of the EM field will increase. On the opposite side of the hill the EM field will decrease. It is important to interpret the VLF-EM signal in conjunction with the digital terrain model (also measured during the survey) to eliminate such topographic effects.

VLF-EM systems are also sensitive to man-made infrastructure such as power lines even though such infrastructure is rarely transmitting at the high relative frequencies of VLF transmitters (17-30 kHz). However, the higher frequency harmonics from such infrastructure will produce measurable responses that are coherent enough to average into a signal that is continuous across flight lines. The anomalies caused by man-made infrastructure are usually easy to identify from Landsat images or by their very linear nature and sudden (and straight) changes in direction. Such interference is noted along the west side of the Miller property corresponding directionally with a known power line passes through the claim area.

VLF-EM systems can detect weakly conductive structures such as faults. In some cases the major fault systems are responsible for transporting gold in sulphide. The gold mineralization may originate within a particular rock unit such as an iron formation and is later remobilized and concentrated within fractures that are related to major structures. Gold can also be transported from a host rock and into a formerly barren rock unit via these same structures (such as the chert-hosted gold occurrences).

Upon analysis of the VLF data collected over the Miller claim area, numerous features were identified in all components of the recorded data, however, there were no clear correlations between the magnetic data and the EM signatures with the Miller claim boundary that didn't also appear to correlate with topographic changes visible in the DTM data.

10.0 Conclusion

The above structural interpretation has identified a wide range of geologic structures including regional and localized folds, faults and cross-cutting fracture zones. Many of the identified structures could have been conduits for hydrothermal transportation of mineralization and should be closely examined in areas where they intersect intrusions, folds or other features of interest. Grab samples should be taken in areas where surface exposure is more likely (characterized by a strong, sharp magnetic signature) along with a soil chemistry analysis, both of which may provide valuable information in advancing this exploration program.

Data surrounding these claims should be analyzed to determine extent and to identify any cross-cutting features no apparent within the claim areas themselves.

11.0 Recommendations

1. Concentrate exploration in areas where delineating structures and faults intersect the regional fold or other features of interest.

2. Conduct ground truthing and possibly geochemistry in areas where the magnetic data suggests near surface exposure.

3. Digital products from this report should be made available in either MapInfo or ArcView format as registered tiff files for integration into a GIS compilation.

4. Conduct an advanced level interpretation of the magnetic data, integrate with geology and possibly model selected structures.

From	To			
0.00	3.25	OB		Overburden.
3.25	155.90	MVOL		Fine- to medium-grained (locally coarse, resembles Gabbro), dark green to black, moderate- to strongly-magnetic, locally amygdaloidal (10.95 to 23.35m) Mafic Volcanics. Minor, medium- to coarse-grained, dark green to red Feldspar Porphyry Dykes are present from 104.4 to 124.6m. The Porphyry primarily occurs as irregular fragments to < 5cm dykelets but larger, up to 35cm dykes are present. The lower contact with a feldspar Porphyry Dyke is broken but appears to be at 60 degrees tca.

Minor, 0.6 to 1.4m, pink to red, aphanitic to locally equigranular Syenite Dykes are present below 189.6m. Narrow, red to pink, Syenite Dykes are present at; 164.10m (5cm at 33/36 tca), 175.23m (9cm at 45/50 tca), 186.9m (10cm at 20 tca), 187.1m (6cm at 15 tca), 188m (6cm at 50 tca), 188.4m (10cm at 20 tca) and 188.85 (17cm at 65 tca). 196.95	199.00	MVOL		Fine- to -medium grained, medium- to -dark green Mafic Volcanic. The first 65cm of this narrow interval may actually be a narrow GAB Dyke (?). It is less altered and slightly coarser grained. The lower contact with Syenite is sharp but irregular.	R331474	196.95	197.60	0.65	0.003	0.04	<1%

199.00	380.45	SY		Medium- to -coarse grained, pink- to -red Syenite (equigranular) with a minor chlorite (altered from biotite) groundmass. Local patches of a more light pink, vuggy, equigranular Syenite occur from; 272.70 to 320.55m and 337.25 to 375.40m. They locally exhibit diffuse to sharp contacts and likely represent a later phase of Syenite. A 24cm, pink, aphanitic Aplitic Dyke is present at 284.05m with sharp upper/lower contacts at 35/50 tca. Pink, vuggy, aphanitic APL Dykes occur locally between 346.95 to 369.20m. The lower contact with MVOL is sharp at 50 tca.	R331476	199.00	199.80	0.80	0.027	0.17	<1%		0.01%

Meterage		Rock type	Minor Litho	Description
From	To			
0.00	2.13	OB		Overburden.
2.13	23.50	GAB		Medium- to -coarse grained, medium- to -dark green Gabbro. Very localized intervals resemble fine- to -medium grained Mafic Volcanics (contacts are difficult to determine). The lower contact with Mafic Volcanics is gradual, no sharp contact was identified.
23.50	33.63	MVOL		Fine grained, medium- to -dark green, massive Mafic Volcanics. The lower contact with a Feldspar Porphyry Dyke is sharp at 55 tca.
33.63	36.45	FPORP		Feldspar Porphyry Dyke with medium- to -coarse, white- to -pink feldspar phenocrysts set in a very fine- to -aphanitic, dark grey groundmass. The lower contact with Mafic Volcanics is sharp at 55 tca.
36.45	88.10	MVOL		Fine- to -medium grained, medium- to -dark green, massive Mafic Volcanics. The lower contact with Syenite is sharp at 40 tca.

0.00	0.87	OB		Overburden.
0.87	25.10	MVOL		Fine grained, dark green, massive, strongly magnetic Mafic Volcanics. The lower contact with Pillowed Mafic Volcanics is marked by the appearance of pillow selvages.
25.10	123.30	MVOLPIL		Fine- to -locally medium grained (within pillow cores?), medium- to -dark green Pillowed Mafic Volcanics. Pillow selvages tend to be dark green, chlorite rich and < 5cm wide. Medium grained, medium green-grey Gabbro Dykes are present at 60.16m (1.39m) and 68.05m (0.50m). The lower contact with Feldspar Porphyry is sharp but irregular.

1.10	45.45	MVOL		Fine- to -locally medium grained, dark green, magnetic, massive Mafic Volcanics. Altered Syenite Dykes (up to 1.75m) and red, aphanitic Aplitic Dykes (<5cm, late) first appear at 28.45m then occur sporadically until 39m. Below 39m, there is a significant increase in both Syenite and Aplitic Dykes which is associated with increased mineralization/alteration within the MVOL. The lower contact with Syenite is sharp at 45 tca.
30.17	30.60		SY	Faded, pale grey- to -red, equigranular- to -porphyritic Syenite Dyke with sharp upper/lower contacts at 20/30 tca.
42.70	44.45		SY	Altered, equigranular- to -porphyritic Syenite Dyke with approximately 5 qtz vlt's/m, 0.5% diss py and locally cut by Aplitic Dykes.

45.45	102.65	SY		Syenite. 45.45 to 90.8m: Equigranular- to -porphyritic, medium- to coarse grained, pink- to -red Syenite with strong hematite-potassic +/-silicification +/- albite which primarily bleaches out the original texture. Minor biotite locally altered to chlorite forms the fine grained groundmass surrounding feldspar. Less than 10% red, aphanitic Aplitic Dykes are also common throughout. 90.8 to 102.65m: Equigranular- to -porphyritic, medium- to -coarse grained, pink, weakly magnetic Syenite with increased biotite-chlorite groundmass (locally up to 30%), minor (1-3cm) Aplitic Dykes and local (<30cm) intersections of strongly magnetic.
