Biogeochemical Survey (2017)
Claim Nos. 1240115, 1240130, 1240142, 1240150, 1240154 & 1240155
Township of Havelock-Belmont-Methuen (Methuen)
Our File No. 17-2357

Dear Mr. Anderson:

We are pleased to provide this report outlining the 2017 results of a biogeochemical survey of your claim group in Methuen Township.

This survey represents an expansion of the grid area from similar surveys completed in previous years and follows the same protocols and techniques. We are pleased to advise that the current survey has revealed the presence of a new anomaly, suggesting the potential presence of a barite-calcite-sulphide vein in the northeastern part of the claim group.

Our report provides a summary of our findings and an interpretation of the data.

If you have any questions, please contact our office.

Yours truly,
Oakridge Environmental Limited

Biogeochemical Survey (2017)

**Claim Nos. 1240115, 1240130, 1240142, 1240150,
1240154 & 1240155**

Township of Havelock-Belmont-Methuen (Methuen)

1.0 Introduction

This report presents the results of a recently completed biogeochemical survey conducted over a series of geophysical (magnetic) anomalies associated with a large meta gabbro body situated in west-central Methuen Township, Peterborough County (Figure 1).

Our 2017 survey represents an extension (to the east) of previous biogeochemical surveys completed in 2009, 2010, 2012, 2013, 2014, 2015 and 2016. The current survey was conducted following the same procedures and protocols as in the previous work.

As the area has little to no natural soil cover, conventional soil-geochemical surveys are not practical. Instead, biogeochemical surveys have been undertaken to determine the distribution of trace metals and to identify any significant areas of potentially economic mineralization. Previous surveys have been very successful in this regard, yielding discrete metal anomalies that we feel would not be discernable using conventional geochemical techniques.

The current survey focusses on an area containing a previously identified multi-element anomaly. Reprocessing of previous data has also been conducted, resulting in minor refinements to our previous interpretations.

2.0 Scope of Work

In completing this mapping program, the following tasks have been completed:

- The results of the previous biogeochemical surveys and earlier geophysical survey data (airborne magnetic and VLF-EM) were reviewed with respect to the location and orientation of the identified anomalies.

- Forest inventory mapping of the claim group area was obtained and reviewed with respect to tree species and potential usefulness with respect to biogeochemical sampling.

- A reconnaissance inspection of the survey area was conducted to determine

prevalent species, age, accessibility, distribution, health of trees for biogeochemical sampling purposes.

- Analytical requirements and protocols were discussed with the laboratory prior to sample collection, to ensure proper analytical procedures were followed.
- The sampling program protocols were implemented and the sampling program was undertaken, utilizing a differential Global Positioning System (dGPS) for determining sample locations. The nominal accuracy of the dGPS is ± 2 m.
- Traverse lines, outcrop extents and other features were determined in the field for plotting purposes.
- All data were plotted and analysed.
- Data from the current and previous surveys were combined, re-plotted and re-interpreted.
- This report was prepared, including all data, our findings, conclusions and recommendations.

3.0 Site Description, Access and Location

The subject claim group consists of six (6) contiguous claims (i.e., Nos. 1240115, 1240130, 1240142, 1240150, 1240154 and 1240155). The location of the claim group is provided in Figure 2. The claim group covers a total area of approximately 366 ha (904 acres). Of that total area, the main part of the 2017 survey covers approximately 17 ha (42 acres). Sampling during the current survey was conducted within south-eastern extent of claim No. 1240154 and within the northern portion of claim No. 1240150.

To access the site from Peterborough, at Highway 115, continue eastward to the intersection of Highway 115 and Highway 7 (Figure 1). Proceed onto Highway 7 eastward to the intersection of Highway 28. Follow Highway 28 (northbound) approximately 16 km to County Road 6 (formerly known as Stony Lake Road). Follow County Road 6 approximately 26.5 km eastward, south of Stony Lake, to County Road 44.

The nearest access trail is located approximately 4.5 km north of the intersection of

County Road 6 and County Road 44. The trail is accessed off County Road 6 via a small parking area 270 m south of County Road 56 (Northey's Bay Road). This trail is unmarked and is utilized by snowmobilers and hunters to enter the crown lands. The trail has been labelled "Route A" on Figure 2.

The claim group is located within a large expanse of Crown Lands on the east end of Stony Lake (Figure 2). Several parcels of privately owned land occur between County Road 6 and the claim group, essentially isolating the site from any kind of public roadway access. Therefore, public access to these lands and the claim group is via a network of trails that start from County Road 6 or via the CN Railway off of County Road 44 and Fire Route 51 south of Long Lake. Much of this area contains both registered and unregistered hunting camps and recreation trails for ATVs and snowmobiles.

The subject claims are held by:

Trigan Resources Inc.
35 Lauren Rd
Port Perry, ON, L9L 2A7
Attn. Mr. Matt Anderson

4.0 Topography and Drainage

The claim group area is generally dominated by bedrock outcrop ridges with very rare pockets of thin, discontinuous granular overburden materials. Most low-lying areas are dominated by extensive wetland areas that contain thick layers of organic material overlying sandy silty bottoms or rock substrates. There are generally insufficient soils in the area to allow for normal geochemical soil sampling. However, it is important to note that the 2017 survey area had comparatively continuous overburden cover along the easternmost extent of the claim group.

The maximum local relief within the survey area is somewhat subdued in comparison to the rest of the claim group, at approximately 5 m with the average relief being about 2 m to 4 m. The topography is essentially dominated by the bedrock structure which consists of a metagabbroic pluton which is thought to be at the core of a local synform, according to published mapping (Kingston, 1985). The topography of the gabbro pluton is somewhat dome-like and as such, the regional drainage pattern tends to be roughly radial - outward from the north-centre of the claim group. Locally, the sequence of parallel rock ridges can distort drainage patterns into long, narrow linear valleys.

In the survey area, drainage tends to be slow, with stagnant conditions common in the summer. The general regional flow pattern appears to be from east to west, although local flows may be quite different as a result of bedrock structure influences.

5.0 Previous Work

Previous exploratory work at the site has included a limited diamond drilling program, which consisted of 10 vertical holes (Phipps, 2003a). The depth of the holes ranged from 31.9 m to 45.7 m. The holes intersected medium grained gabbro, with absorbed metasedimentary inclusions, cut by granitic dikes.

Representative samples from each borehole were submitted for aggregate testing. Results of these tests were all positive and show that the bedrock, in the area of the gabbro covered by the boreholes, is suitable for aggregate resource material (Phipps, 2003b).

The gabbro body is somewhat layered, consisting principally of gabbro intruded by irregular masses of granitic material. Along the pluton's western boundary, the stratigraphy consists of layered metasediments, granitic gneiss and gabbro.

In addition to the diamond drilling, a baseline hydrogeochemical study was conducted (King, 2005) for the purpose of comparing trace element concentrations (i.e., major ions and metals) in surface water and groundwater between subwatersheds. That study revealed interesting and highly defined geochemical differences between the subwatersheds, potentially indicating future targets for metal exploration.

Geological mapping was conducted in 2006 (King, 2007) to determine the limits of the gabbro body and to examine transitional contact relationships in the surrounding country rock.

A fixed wing magnetic and VLF survey was conducted over the entire claim group (Webster, 2008) revealing the presence of several large magnetic and conductive anomalies which appear to be associated with the contact zone surrounding the meta gabbro body.

An experimental biogeochemical survey was conducted in 2009 (King, 2009) to explore part of one of the larger geophysical anomalies identified by the 2008 airborne survey (Figure 3). The biogeochemical survey was successful, revealing the presence of several multi-element anomalous zones which appeared to correlate with the geophysical survey results. These included base metal and precious metal anomalies. Follow-up biogeochemical surveys were conducted in 2010 (reported in 2011), 2012, 2013, 2014, 2015 and 2016 expanding on the previous grid areas. The current program (2017) continues to expand on the previous surveys, focussing on the eastern extent of the claim group.

6.0 Geology

6.1 Regional Setting

The claim group is situated less than 2 km north of the southern boundary of the Canadian Shield. While this area is known to contain Paleozoic outliers (such as those near Oak Lake), none have been observed within the claim group.

The claim group is within the “Belmont Domain,” a sub-component of the Elzevir Terrain within the Central Metasedimentary Belt of the Grenville Province (Precambrian). The Elzevir Terrain is characterized by volcanic and related sedimentary rocks which formed around a group of “volcanic centres”. These span much of north-central Hastings County and northern Peterborough County, extending from the southern edge of the shield to about Bancroft in the north. These rocks are intruded by a series of gabbroic complexes which are remarkably similar in chemical composition (e.g., Thanet Complex, Tudor Metagabbro, Cordova Gabbro, Duck Lake Sill, etc.).

In the study area, the closest volcanic centre would likely have been about 15 km to the southeast where the “Belmont Volcanics” occur. To the northwest, the volcanics yield to a thick band of volcanically derived metasediments which underlie the Oak Lake area, immediately east of the claim group. Structurally, this sequence is referred to as the Oak Lake Antiform.

The gabbro/metagabbro¹ within the claim group is a relatively small un-named mafic intrusive body (Figure 4, Regional Geology Plan). This small pluton, referred to herein as the “West Gabbro”, occurs at the core of a small synform feature with an arcuate, ENE-WSW axial trend. Granitic gneiss and metasediments are wrapped around the pluton. Late transgressive granitic intrusions and inclusions of metasediment occur within the gabbro body. These are evident in the diamond drill core logs from a previous drill program (Phipps, 2003a).

Published mapping of the area (Kingston, 1985) shows the gabbro pluton as an oval shaped body with a generally east-west long axis. In the field, the pluton has a much more complex and irregular shape which includes a series of finger-like granite porphyry bands that appear to extend into the pluton.

A similar, “East Gabbro” body also occurs approximately 11 km to the east and is the subject of a traprock quarry operation. The West Gabbro is also of interest with respect to future traprock production.

¹ Published mapping suggests that bodies of this type (in this area) may include diorite, gabbro, hornblendite, pyroxenite, anorthosite, metagabbro and amphibolite.

According to Ontario Geological Survey Special Volume 4 (Geology of Ontario), a variety of metallic mineralization types are known to occur in the gabbros of the Central Metasediment Belt. These include magmatic deposits consisting of disseminated copper and nickel. Iron and titanium deposits are also known in the gabbros. Stratiform sulphide lenses have reportedly been identified, consisting of chalcopyrite, pyrrhotite, pyrite, and sphalerite. Occurrences of stratabound volcanogenic massive sulphides are also known or suspected in the region.²

All Precambrian rocks in the area have been metamorphosed to middle-upper amphibolite facies (Bartlett, 1982).

6.2 Survey Area Geology

The local geology is exposed by rock cuts along the rail line which extends from Havelock in the south, northward to Nepton and Blue Mountain (nepheline syenite mine). The local rock cuts and outcroppings expose a sequence of granitic gneiss, metasediments, gabbro, diorite/metadiorite and pegmatite. The contact relationships between the West Gabbro pluton and its surrounding rocks are relatively consistent, although irregular.

Porphyritic granite occurs widely in the claim group and is present in the survey area. The porphyritic granites appear to have been emplaced in linear bands, possibly intruding the original bedding planes of the host metasediments and also within the gabbro. Occasional narrow quartz veining occurs in the granite, typically with minor sulphide mineralization. Some finer grained late granitic veining and zoned pegmatite also occur within the porphyritic granites. The granites also include narrow bands of metasediments and finely crystalline mafic rocks.

It is apparent that the gabbro magma has reacted with the wall rocks creating a zone of hybrid rocks transitional between the gabbro and adjacent country rock. The contact zone consists largely of layered meta-granodiorite and/or monzonite, with interbeds of metasedimentary rock and porphyritic granite. The Transition Zone is up to several hundred metres in width, is highly variable and appears to be narrower along the northwestern edge of the pluton. The gabbroic rocks occur principally within a “core” zone situated in mid-northern Claim 1240130.

The gabbro consists of a medium to coarsely crystalline, dark grey to black mixture of mafic plagioclase, olivine-clinopyroxenes (gabbro) and hornblende (diorite), with minor biotite. Rare to occasional specks of pyrite and/or pyrrhotite occur, although most of the gabbro contains no appreciable sulphide. Portions of the gabbro are weakly layered or

² Previous diamond drilling in the claim group did not reveal any significant occurrences of sulphide mineralization.

foliated, however, for the most part, the gabbro appears relatively unaffected by metamorphism (although it is likely annealed).

The gabbro appears to be iron-rich and consistent with the typical tholeiitic composition of the volcanic rocks and mafic intrusives of the Belmont Domain as described by Lumbers (1969) and by Holm, et al. (1986).

7.0 2017 Biogeochemical Survey

7.1 General

Tree roots can extract metals and other elements from many cubic metres of soil, overburden, groundwater and bedrock. These metals are then transferred to aerial parts of the tree where they may concentrate. Data derived from the analysis of an appropriate vegetation sample medium permits geochemical mapping and the potential detection of geochemical anomalies that reflect the underlying metal content of the soil, rock and/or groundwater. This technique can be especially useful in areas where conventional soil-geochemical methods are not practical, due to minimal soil cover.

Biogeochemical sampling can provide similar results to those obtained from standard soil geochemical surveys. However, the tree extracts elements from a large volume of material of diverse composition, including groundwater. Some elements that are dissolved in groundwater can be readily extracted by the tree roots, but may not be precipitated on soil particles, thus a different suite of responses is possible, in comparison to standard soil geochemical prospecting methods.

Because each species of plant has a different requirement for, and tolerance to, a range of chemical elements, some partitioning of elements takes place and there is selective absorption and transference into the plants. For biogeochemical exploration, conifers are good sample media because they are primitive plants that have a wide tolerance to many trace elements.

The outer bark is generally considered a repository for many elements that do not fit elsewhere or are not required for the metabolic function of the tree. Some elements may be excluded from uptake at the roots or may only be partially absorbed, and some may be taken up but dispersed among tree tissues to the extent that inter-site variations are so small that they cannot be detected. The work of Springer, et al. (1988) suggests that biological uptake of metals in some tree leaves may be “capped”. This does not, however, appear to be the case for tree bark, based on our experience to date. Regardless, such factors need to be taken into consideration when interpreting geochemical results.

7.2 Survey Methodology and Protocols

Prior to conducting the sampling program, published mapping resources were consulted with regard to the vegetation types present in the survey area. Updated SOLRIS Ontario Land Cover Compilation Version 2 mapping (Figure 5) is a primary data layer that provides a comprehensive, standardized landscape level inventory of natural, rural and urban lands in Ecoregions 6E and 7E, current to 2015. The mapping is based on MNRF's Ecological Land Classification (ELC) for southern Ontario (Lee et al., 1998).

A reconnaissance / feasibility inspection of the survey grid area was undertaken on September 20, 2017 to verify the types of vegetation and the viability for sampling in the expanded grid area. At that time, it was determined that the grid area contained a sufficient number of similar aged Eastern White Pine (*Pinus strobus*) with a reasonable areal distribution to permit expansion of the previous sampling area. The sampling commenced at once.

Other species that could potentially be sampled were also present, however, White Pine were found to be the most abundant and accessible. Given the large amount of wetland present, the survey focussed on areas of outcrop where this species occurs. Sampling of other species was not conducted.

During a previous survey, new growth twigs and needles were collected from smaller diameter, younger and/or less developed trees as an experiment to determine the viability of other sampling approaches. That experiment yielded interpretable results, however, may not have provided the same sensitivity and the results did not appear to correlate well with the bark data. As such, only bark samples were collected in subsequent surveys, including 2017.

The main sampling period for the 2017 biogeochemical survey was conducted from September 20, 2017 to October 10, 2017. Fieldwork was conducted and/or assisted by the following individuals:

- Mr. Dan MacIntyre, BSc., Peterborough, ON. (Senior Hydrogeological Technician)
- Mr. Brad Pettersone, BSc., Peterborough, ON. (Senior Environmental Technician)
- Mr. Matthew Dimitroff, Peterborough, ON. (Environmental Technician)

The work was supervised and directed by Mr. Brian King, P. Geo., of Peterborough, ON.

Samples of loose outer bark were collected by scraping the circumference of the tree from approximately 0.75 m to 1.0 m height using a rigid plastic (i.e., non-metal containing) scraper. Only trees with diameters in the range 12 cm - 24 cm were sampled, to ensure similar ages. The samples were removed by cutting with a plastic (non-metal containing) serrated knife. All sample materials were transferred to "ziplock" plastic bags which were tagged in the field. Each sample location was determined in the field using differential

GPS (accuracy ± 2 m).

Figure 6 illustrates the sampling equipment used during the survey.

As in the previous surveys, the typical sample size was approximately 40 g. The amount of sample material varied, depending on the condition of the tree. Only the loose, outer bark was removed so as to not harm the tree. Care was taken not to include the inner bark as its composition is substantially different from that of the outer bark. Whereas there are seasonal variations in the chemistry of twigs and leaves, the chemistry of the outer bark does not change during the course of the year; this is because the bark is dead tissue that can be collected at any time. Moreover, samples from different survey periods can be integrated without the need to normalize data to a common datum.

During the survey, a total of 106 bark samples were collected and analysed. These include two duplicate samples for QA/QC purposes. Figure 7 illustrates the locations of all grid samples with respect to the subject claims.

All field data were entered into the existing MS Excel database upon returning to our offices. At that time, all samples were individually inspected and any visible non-bark materials (“debris”) were removed. Non-bark materials largely consisted of pine needles, insects, hardened tree gum and occasional plastic fragments from the scrapers. All samples were air-dried prior to shipment.

Following the inspections, samples were counted, weighed and boxed for shipment to AGAT Laboratories in Mississauga, Ontario.

7.3 Analytical Data

At the laboratory, the samples were reduced to ash by controlled ignition at 480°C for 24 hours. They were then digested in strong acid (aqua regia) and the solution analyzed for 51 elements by inductively coupled plasma mass spectrometry (ICP-MS). All 2017 data are presented in Appendix A. Data were provided electronically by the laboratory.

8.0 Analysis & Interpretation

8.1 General

The interpretation of biogeochemical data should be undertaken with due consideration of the chemical requirements and tolerances of plants. Plants require certain elements for their survival, and they have the ability to concentrate metals by scavenging them from the substrate. Zinc (Zn), for example, is needed for plant metabolism. Therefore, subtle differences in Zn concentrations between sample sites could simply reflect the health of

the plant and may not indicate significant differences in the chemistry of the substrate. However, major differences in Zn concentrations may reflect the presence of Zn mineralization.

In contrast, plants also have the ability to exclude those elements that would have a detrimental effect on their growth or health (referred to as the “barrier” effect), thus only weak enrichment of an element may occur in an environment where that element may have an anomalously high concentration in the soil or groundwater. As a consequence, there is not always a simple relationship between the chemistry of tree tissue and the chemistry of the soil and underlying parent material for some elements.

8.2 Data Management

To facilitate interpretation of the biogeochemical data, the laboratory results were entered into a Rockworks database for processing. The output from Rockworks was then loaded into an ArcGIS database to determine the spatial significance of the data.³

Based on our review of the 2017 data and the compiled results of the previous surveys, we have focussed our current data assessment on those parameters which have sufficient response to provide anomalies and for which discrete trends are visible.

For each analytical parameter considered, the areal distribution of that parameter was plotted and contoured for presentation. Contouring was undertaken using the Kriging method. The contoured element plots are presented in Appendix B.

In addition to the areal data, histograms for each parameter of interest were prepared and added to the corresponding plots to illustrate the statistical distribution and provide the mean value and standard deviation.

8.3 2017 Data Interpretation

Data from the 2017 survey appear to be continuous and form discrete areal concentration anomalies, indicating that the biogeochemical technique remains robust.

The 2017 survey was intended to expand the sample grid along part of the eastern claim group boundary where previous data were sparse. Using GIS, we were also able to further refine some of our previous anomaly interpretations. A brief description of our 2017 findings is presented below.

³

The software Rockworks provides a variety of statistical and mapping modules for this purpose.

The new data have allowed further refinement of previously identified anomalies and revealed the presence of a new anomaly which occurs in the northeastern-most part of the 2017 grid area (referred to as “Anomaly VI”). This zone is comprised of multiple samples and appears to be continuous in that area, albeit on the eastern terminus of the claim group. The anomaly is dominated by a local high concentration of Strontium (Sr) within a large and discrete area. Other characteristics of Anomaly VI include:

- a localized core zone of Ba enrichment;
- a zone of Fe and Mn depletion is apparent along the eastern edge of the claim group suggesting some form of alteration, especially with respect to Mn;
- a general area of weak K and Na enrichment;
- a core zone of Mg enrichment that correlates with Ba and other parameters;
- a general zone of Pb enrichment;
- a fairly discrete zone of S enrichment, exhibiting an apparent linear trend, roughly along Azm 120°;

In addition to identifying the new Anomaly VI, the 2017 data have also allowed improvements to our earlier interpretations, including:

- Al occurs at a low concentration (i.e., background level), thus the 2017 data further confirm the eastern and southern extent of the Al rich part of Anomaly II;

The association of Ba, Mg, Sr and S with possible depletion of Fe and Mn in Anomaly VI appears to be a unique assemblage for this property. It is not clear what type of potential mineralization could be responsible for this assemblage. However, we note that the geochemical signature could be consistent with the occurrence of barite-calcite-galena (\pm sphalerite) veining, not previously observed within this claim group.

That type of deposit is well known to occur in the former Bedford Township, Tudor Township and in the southeastern corner of Methuen Township (Uglow, 1916). These comparatively late-stage vein systems generally have NW or WNW trends that reflect the regional tectonic setting at the time of emplacement. In this regard, there is a possible linear trend in our S data for Anomaly VI that would be consistent with that orientation. Most interestingly, the known occurrence in Methuen Township appears to have been reported as a locality for the strontium rich mineral celestite (Ontario Legislative Assembly, 1897).

While the barite-calcite veins are of considerable interest to mineral collectors and did historically support several small-scale mining operations, we are not aware of any recent

instances where these have representing significant exploration targets. These tend to be very narrow-vein deposits with sporadic sulphide mineralization. As such, Anomaly VI does not appear to represent a significant exploration target at this time.

The 2017 data also confirm our previous interpretations, primarily with regard to the characterization and extent of Anomaly II. It also further defines the background concentrations of Mg, Ce, Cs, Rb and Al which allows for refinement of all other previously identified anomalies.

The 2017 data have been compiled with the results of previous surveys and geochemical anomalies have been interpreted based on the various element concentrations and/or zonations. These are briefly described below and are identified on the updated Interpretive Plan, Figure 8.

Anomaly I

Anomaly I occurs in the northwestern corner of Claim 1240130 (i.e., at junction of Claims 1240142 & 1240154). Anomaly I is characterized by elevated Au, Fe, Cd, Mn, Mg, Pb, Ni, Rb, V, Y and Zn. A weak correlation with Ag, Cd and S was also thought to be present. This anomaly continues to stand out given the widespread presence of Au. The 2017 data have not changed our interpretation of this anomaly, other than Rb being slightly elevated above the new background concentration.

This anomaly appears to be associated with the main contact zone between the country rock and the outer transition zone surrounding the gabbro. Published mapping indicates that this area may also contain rusty paragneiss and schist. It also correlates with the north flank of a large magnetic anomaly.

We continue to interpret Anomaly I as a potential mineralized occurrence, perhaps related to the rusty schist host rock (which could include mineralized quartz veining or pegmatite).

Anomaly I continues to be considered a high priority target for future exploration.

Anomaly II

Anomaly II consists of elevated concentrations of Au, Al, Cd, Mn, Mg, S, Y and Zn.

Anomaly II continues to be considered a high priority target with respect to Au.

Anomaly III

Anomaly III occurs as an east-west band crossing through the central part of the claim group and is the largest identified biogeochemical anomaly. No significant changes to this interpretation result from the 2017 data.

Anomaly III is characterized by elevated base metals (Zn, Pb, Cd) and S in bark. The eastern part of the anomaly exhibits possible Na depletion. A weak Au anomaly also occurs within this zone, near the centre of claim 1240130. This anomaly also appears to have discrete metal sub-anomalies, possibly suggesting fractionation or zonation.

Anomaly III occurs in the centre of the main gabbro body. The gabbro is thought to be somewhat layered and contains zones where inclusions of country rock are more prominent. The geological mapping data do not provide any clear indication that Anomaly III coincides with such a zone. Similarly, there is no clear topographic expression that would suggest an accumulation of metals in sediment or groundwater. Anomaly III does, however, correlate with broad anomalies identified by the airborne magnetic survey.

Based on the above, we interpret this anomaly to potentially represent a deeply buried zone of base metal sulphide enrichment within the gabbro body.

Anomaly III is considered a medium priority target that will require further work to provide better definition of targets.

Ti Boundary

The compiled bark data indicate that there is a distinctive boundary separating the southern third of the survey area from the rest of the grid. Ti values clearly increase south of Anomaly III, reaching a maximum along the southern boundary of claim 1240130, coinciding with the mapped southern contact of the main gabbro body. No changes to our interpretation of the Ti boundary have resulted from analysis of the 2017 data.

It is not clear how to interpret this result other than as a compositional change in the underlying rock. However, it is also conceivable that an ilmenite rich segment of the gabbro may underlie the southern part of the gabbro, perhaps at depth, resulting in the broad geochemical Ti signature. In this regard, we also note that there are significant magnetic anomalies associated with the enrichment which could be related.

In this geological environment, elevated Ti may be highly significant. A similar gabbroic body that contains an important ilmenite deposit (also Trigan Resources) occurs east of the claim group. As such, any anomalies that suggest the presence of a similar deposit in the West Gabbro body are of considerable economic interest.

Anomaly IV

Anomaly IV is situated immediately south of the 'Ti Boundary' (see description above), in the southwestern part of the compiled survey area within Claim 1240130. This anomaly is based entirely on previous data and is characterized by elevated Ni, Cu, Co, Ba, Mo and Ag. Anomaly IV correlates with a magnetic anomaly that occurs along the southern boundary of the main gabbro body. No changes to the previous interpretation of Anomaly IV have resulted from the 2017 survey.

Anomaly IV appears to indicate the potential presence of metal enrichment in the gabbroic rocks. Anomaly IV is now considered a lower priority target, primarily based on its size.

Anomaly V

Anomaly V consists of elevated concentrations of Ag, Cd, Mn, Na, Sr and Y.

Anomaly V continues to be considered a high priority target with respect to Ag.

Anomaly VI

Anomaly VI is a new finding. See above for a description of this zone.

8.4 Discussion

Other than the rail line which passes through the survey area, the subject lands have not been disturbed and are undeveloped. As such, there are no known man-made factors which would account for any of the anomalies identified by the survey. Airborne dust, for example, would not appear to be a significant factor in this area. As such, it is likely that the anomalous geochemical values represent real occurrences in those areas, subject to the variability expected from this survey method.

In the almost complete absence of terrestrial soils, the biogeochemical survey is likely to provide results that are directly related to the chemistry of the underlying bedrock. White Pine tree roots extend into fractures in the rock where (presumably) some residual soils have accumulated in response to weathering. The roots are also likely to penetrate to the water table, thereby sampling local groundwater. Anomalous element concentrations in bark and/or twig samples should represent real accumulations (or depletions) of those elements in the underlying soil, rock and/or groundwater (subject to biological sensitivity considerations, etc.). As part of the 2017 grid area was found to have some overburden, the possibility of soil-related effects cannot be completely discounted, however, nothing in the current data suggest this to be an issue.

While the survey grid is mostly within the mapped boundary of the main gabbro body, differentiated rock units occur within and surrounding the gabbro, not the least of which are inclusions of felsic gneiss and pegmatite. As such, some of the geochemical patterns may be attributed to varying composition within the gabbro and/or any associated lithological transition zones.

According to Wilson (1994), there are four main Classes of metal deposits associated with mafic intrusives within the Grenville Province:

- Gabbro-hosted magmatic Ni-Cu sulphide deposits, such as the examples in the Raglan intrusive complex, in which there is evidence for sulphide liquid immiscibility. Anomaly IV appears to be of this assemblage.
- Gabbro-hosted Fe-Ti oxide deposits, of variable *magnetite : ilmenite* ratio, with accessory sphene and apatite, also related to magmatic processes. These may also contain minor sulphides, some of which have been mined, and which also seem to be magmatic concentrations (e.g., Lavant). The area south of the 'Ti Boundary' would potentially appear to be consistent with this type of mineralization.
- Zn deposits in metamorphosed carbonate scarns associated with gabbro, (e.g., the Long Lake Zn mine). None of the identified biogeochemical anomalies appear consistent with this type of occurrence.
- Au-Ag mineralization, of late (epigenetic) origin, hosted in shear zones along the intrusive margins (e.g., Cordova Gabbro). Anomalies I and II could possibly be indicators of this deposit type. Anomaly II is especially interesting due to the presence of Au with a variety of other elements that are commonly associated with precious metal occurrences, plus an accompanying (off-set) Na depletion zone.

Zinc is a dominant component of some of the anomalies at this site (not including Anomalies V and VI), likely due to its mobility. The correlation with other base metals and sulphur appears to suggest the potential presence of base metal sulphide mineralization (especially Anomalies II and III). Anomaly III does not appear to fit well with the above listed deposit types, however, could represent a different type of gabbro-hosted base metal enrichment. New Anomaly VI may represent a new type of occurrence, related to late-stage barite-calcite-galena veining which is not likely to be genetically related to the host rocks. For all anomalies, it must also be recognized that biogeochemical data may not yield classic geochemical anomalies.

Occasional examples of gossanous rocks have been noted within the claim group, also suggesting the presence of that type of mineralization. As such, we feel that Anomaly III remains the most important *base metal* exploration target identified within the claim group to date. Anomalies I, II and V represent the most important *precious metal* targets.

The “Ti Boundary” also suggests that there is a widespread compositional shift in the southern part of the survey area. As this area is also associated with a significant magnetic anomaly in the southern part of Claim No. 1240130, we feel that there is some potential for the occurrence of ilmenite mineralization in that area (or further south). Unfortunately, a specific target cannot be resolved from the available data. However, we also feel that further geophysical work, possibly including data re-interpretation, could identify future targets for follow-up exploration.

9.0 Conclusions & Recommendations

- 9.1 The compiled biogeochemical survey has revealed the presence of significant trace element anomalies over a wide area. The 2017 data expand the grid area to the east, revealing a new Strontium (Sr) anomaly (referred to as “Anomaly VI”) and confirming the boundaries of previous interpreted anomalies.

We feel that new Anomaly VI is a minor area of interest in comparison to the other identified anomalies within the claim group.

- 9.2 Anomaly II appears to represent the most prospective zone for future prospecting, exhibiting a widespread, low amplitude Au anomaly, associated with several other parameters and a discrete zone of Na depletion. Anomaly II appears to be centred in the western half of Claim 1240154. The 2017 survey has confirmed the eastern boundary for Anomaly II.

- 9.3 The central anomaly ('Anomaly III') appears to be consistent with the potential presence of base metal sulphide mineralization, occurring across a wide band in the central part of the main gabbro body. Anomaly III also straddles two large magnetic anomalies.

We continue to recommend that prospecting along this trend be conducted in an effort to determine whether there are any surficial indicators of mineralization and if any, what style of mineralization is present. The magnetic anomalies should be targeted for follow-up exploration by diamond drilling.

- 9.4 The area south of the ‘Ti Boundary’ and the presence of magnetic anomalies in the southern part of Claim 1240130 suggest that ilmenite mineralization could be present at depth, perhaps within a buried extension of the gabbro. Unfortunately, we cannot resolve any specific exploration targets from the available data, other than the magnetic anomaly.

Therefore, it is recommended that additional work be conducted to further evaluate the potential for ilmenite mineralization south of the Ti Boundary. As a first step, we would

recommend additional evaluation (i.e., modelling) of the available geophysical data. We also recommend that prospecting in the southern part of Claim 1240130 and northern part of Claim 1240155 be conducted in an effort to determine whether there are any surficial indicators of ilmenite mineralization. Any areas of interest should be explored by diamond drilling.

- 9.5 Anomaly I continues to represent an interesting potential occurrence of Au. Typically, Au occurrences in this area are within small quartz vein systems. Rare examples of Au bearing pegmatites are also known to occur.

We recommend that prospecting within and around Anomaly I be conducted in an effort to determine whether there are surficial indicators of mineralization and the style of mineralization present, if any.

- 9.6 Anomaly V continues to represent an interesting potential occurrence of Ag. Similar to Au, the occurrences of Ag are typically found within small quartz vein systems.

We recommend that prospecting within and around Anomaly V be conducted in an effort to determine whether there are surficial indicators of mineralization and the style of mineralization present, if any.

End of Report

Sincerely,
Oakridge Environmental Ltd.

Brian R. King, P. Geo.

Statement of Qualifications

I, Brian R. King have been practising in the fields of environmental geology, hydrogeology and economic geology for more than 30 years. I am a Registered, Practising Professional Geoscientist (Ontario Reg. No. 0396). I have supervised the design of, collection of data for, and interpretive work involved in this study.

As a principal and the president of Oakridge Environmental Ltd., I am authorized to conduct and report on geological, hydrogeological and mineral exploration related studies and investigations.

My educational background includes completion of an Honours Bachelor of Science degree from Brock University, specializing in the geological sciences including hydrogeology, geochemistry and environmental science. I have completed continuing education courses in groundwater contaminant assessment from the University of Waterloo and have completed the Ministry of Environment's "Hydrogeological Technical Information Requirements for Land Development Applications," among other environmental courses.

Brian King holds memberships in the following organizations:

Practising Member of the Association of Professional Geoscientists of Ontario
Member of the International Association of Hydrogeologists

It is further stated that neither Oakridge Environmental Ltd. nor its employees have any ownership interest in the subject property and that the only remuneration to be received is monetary and that the remuneration is solely related to the work completed as outlined in this report.

Brian R. King, P. Geo.

Comments: RDL - Reported Detection Limit; G / S - Guideline / Standard

8823874-8823919 Samples were ashed in a muffle furnace at 550°C. The ashed material was digested with concentrated HNO₃/HCl and digestates analysed using ICP/MS and ICP/OES. The results reported are concentrations of the elements in the ashed material.

Elevated RDLs indicate the degree of sample dilutions prior to analysis in order to keep the analytes within the calibration range of the instruments and to reduce matrix interferences.

Comments: NA signifies Not Applicable.

Duplicate Qualifier: As the measured result approaches the RL, the uncertainty associated with the value increases dramatically, thus duplicate acceptance limits apply only where the average of the two duplicates is greater than five times the RL.

High RPD for sample and duplicate is due to the matrix and heterogeneity of the sample.

Chain of Custody Record

If this is a Drinking Water sample, please use Drinking Water Chain of Custody Form (potable water consumed by humans)

Report Information:

Project Information:

Project: West Gabbro
Site Location: Havelock-Belmont-Methuen, Ontario
Sampled By: Dan MacIntyre, Brad Petterson, Matthew Dimitroff
AGAT Quote #: 182363 PO: 17-2357

Please note: if quotation number is not provided, client will be paid full price for anesthesia.

Invoice Information:

MISCELLANEOUS ANALYSIS REVIEWED BY: Mike Muneswar, BSc (Chem), Senior Inorganic Analyst

DATE REPORTED: Nov 30, 2017

PAGES (INCLUDING COVER): 17

VERSION*: 1

Should you require any information regarding this analysis please contact your client services representative at (905) 712-5100

*NOTES

All samples will be disposed of within 30 days following analysis. Please contact the lab if you require additional sample storage time.

Comments: RDL - Reported Detection Limit; G / S - Guideline / Standard

8824146-8824192 Samples were ashed in a muffle furnace at 550°C. The ashed material was digested with concentrated HNO₃/HCl and digestates analysed using ICP/MS and ICP/OES. The results reported are concentrations of the elements in the ashed material.

Elevated RDLs indicate the degree of sample dilutions prior to analysis in order to keep the analytes within the calibration range of the instruments and to reduce matrix interferences.

Comments: NA signifies Not Applicable.

Duplicate Qualifier: As the measured result approaches the RL, the uncertainty associated with the value increases dramatically, thus duplicate acceptance limits apply only where the average of the two duplicates is greater than five times the RL.

High RPD for sample and duplicate is due to the matrix and heterogeneity of the sample.

Comments: RDL - Reported Detection Limit; G / S - Guideline / Standard

8824221-8824247 Samples were ashed in a muffle furnace at 550°C. The ashed material was digested with concentrated HNO₃/HCl and digestates analysed using ICP/MS and ICP/OES. The results reported are concentrations of the elements in the ashed material.

Elevated RDLs indicate the degree of sample dilutions prior to analysis in order to keep the analytes within the calibration range of the instruments and to reduce matrix interferences.

Comments: NA signifies Not Applicable.

Duplicate Qualifier: As the measured result approaches the RL, the uncertainty associated with the value increases dramatically, thus duplicate acceptance limits apply only where the average of the two duplicates is greater than five times the RL.

High RPD for sample and duplicate is due to the matrix and heterogeneity of the sample.
