INTRODUCTION

Between May 22nd, 2020 and June 15th, 2020, New Found Gold Corp conducted a mechanized trenching/stripping and channel sampling program on the FP Zone on its Lucky Strike property in Ossian Township. The FP Zone lies approximately 13 kilometres northeast of the town of Larder Lake, Ontario. The FP Zone and stripping area is contained within crown claim cell #237913 & #260665. Though the work falls within a single cell two cell numbers are assigned to the cell due to underlying agreements. The Lucky Strike property has a surface area of 11,360.8 hectares and contains 639 single cell claims. The purpose of the stripping-channel sampling program was to follow-up and ascertain the nature of gold mineralization identified and sampled during a prospecting-reconnaissance program during the summer of 2018, and a previous stripping-channel sampling program in 2018. The work was conducted in the field by Ken Rattee (Project Geologist), Dave Eves (Geotechnician) and Sarah Taylor (Geologist). Canadian Exploration Services Ltd. of Larder Lake, Ontario was contracted to provide the heavy equipment and operator for the excavating of the stripping and provided a labour crew and equipment for the bedrock washing and channel sampling. The mechanized stripping is permitted under the Ministry of Energy, Northern Development and Mines Permit PR-17-11118 expiring on July 13, 2020.

LOCATION AND ACCESS

The FP Zone where the mechanized stripping was conducted lies approximately 13 kilometres northeast of the town of Larder Lake, Ontario. The area is accessible from Larder Lake by travelling east via truck along Highway 66 to Larder Station Road, 1 kilometre east of town. Then travelling north along Larder Lake Station Road for 15 kilometres to a bush trail on the eastern side of the road, just past the 13 kilometre marker sign on the Larder Lake Station Road. On an ATV this bush trail is followed east for 4 kilometres to the FP area. The stripping area is centred at UTM coordinates 602415 East, 5339240 North. (Refer to Fig. 1 - Road access for the Lucky Strike property)

LUCKY STRIKE PROPERTY

The Lucky Strike property is comprised of 639 single cell claims. (Refer to Appendix A – Lucky Strike Property Claim List) The cell claims cover an area of 11,361 hectares.

The rocks underlying the property are of the Lower Blake River Group and are dominated by intermediate to mafic, massive volcanic flows. The volcanic flows have been intruded by diorite-gabbro and syenite. The syenite hosts the gold-bearing quartz-ankerite veins of the Walsh Mine. The long axis of this syenite intrusion strikes approximately north-south and extends for 3.5km on the property and another 3km south of the property and is generally 0.5km wide. Two major regional faults cross the property, the Misema-Misty Lake Fault and the Mulvern Fault, striking roughly in a northeast-southwest direction. These structures have been speculated as being a continuation of the Kirkland Main Break Fault system which hosted the seven historic gold mines of the Kirkland Lake Gold camp. The Victoria Creek Deformation Zone, possibly a splay off the Misema-Misty Lake Fault and a control on the Victoria Creek and Upper Beaver Mines, lies just south of the property with splay structures extending onto the property. (Refer to Figure 2 – Lucky Strike Geology)

The Walsh/FP area hosts the Walsh Mine, initially developed in 1924 with a two compartment shaft sunk to a depth of 157m with 915m of lateral development on four levels at 43m, 76m, 114m and 152m depth. No production records have been found in the historical record though small bulk samples reportedly processed in 1933 graded up to 64.12g/t Au. Three mineralized quartz-ankerite veins, hosted by a syenite intrusion, varying in widths from 7cm to 1.5m have been outlined on surface with strike lengths up to 150m. Surface grabs from the veins in 2011 assayed up to 19.4 g/t Au. The FP Zone lies approximately one kilometre southeast of the Walsh Mine along the northwest-southeast trend of the mineralized Walsh veins and is currently defined by a high grade DDH intersection and a series of channel samples. The DDH (AR-10-30) was drilled in 2010 by Ateba Resources. It returned an assay of 8.5 g/t Au over 3.7m at a vertical depth of 195m. This intersection projects to a wide, altered, pyritic-ankerite zone on surface outlined by numerous old pits and trenches. The channel samples were taken by New Found Gold Corp. in 2018. A 2017 IP survey (New Found Gold 2017) shows a broad high chargeability / low resistivity region corresponding to the surface mineralization suggesting the zone is much wider than surface mapping and prospecting would indicate.

During the summer of 2018, a reconnaissance and prospecting program was conducted over the area (refer to Work Report on the Summer 2018 Surface Prospecting Program, Lucky Strike Property, New Found Gold Corp.). A series of very old, overgrown trenches and pits appear to trace a zone of altered, bleached, fine-grained, mafic volcanics. Ankeritic alteration was strong locally as evident by prevalent highly iron oxidized patches. The zone exhibited a moderate to strong pyrite ± chalcopyrite mineralization with local concentrations up to 30% though typically <10%. Irregular quartz stringers, generally less than 3cm in thickness, were noted locally. The zone appeared to strike in a northwest-southeast direction similar to the strike direction of the Walsh mineralization and could be traced on surface, as defined by the old trenches and pits, for approximately 300m. The area in the vicinity of the highest grading sample from the reconnaissance program, assaying 3.88 g/t Au, at location 602424E, 5339214N was chosen for stripping in order to appraise the quality and continuity of the mineralization through systematic channel sampling.

FP STRIPPING & CHANNEL SAMPLING

The stripping was carried out over 8 days between May 28th, 2020 and June 11th, 2020, in warm, generally clear, late spring weather. (Refer to Appendix E, Daily Work Log). The excavator used, contracted from Canadian Exploration Services Ltd., was a Caterpillar 320BL. The stripping area was covered by thin overburden no more than 50cm at its deepest depth, typically less than 30cm and excavator work progressed quickly. After two days an area approximately 65m x 8m was opened covering a surface area of approximately 795m² (see Fig. 3). Minimal overburden was stockpiled and was smoothed out over wet, swampy ground on the northeast side of the trenching area. Using an average overburden depth of 0.3m it is estimated that the volume of overburden stripped was approximately 250m³. Washing of the outcrop with a high-powered water pump was carried out over the period May 29th, 2020 to June 5th, 2020 with a 2 man crew contracted from Canadian Exploration Services Ltd. 37 channels were marked for channel sampling with a total length of 193.2m. 196 separate intervals were marked for sampling. The longest sample interval marked was 1.4m in length, while the shortest was 0.5m in length.

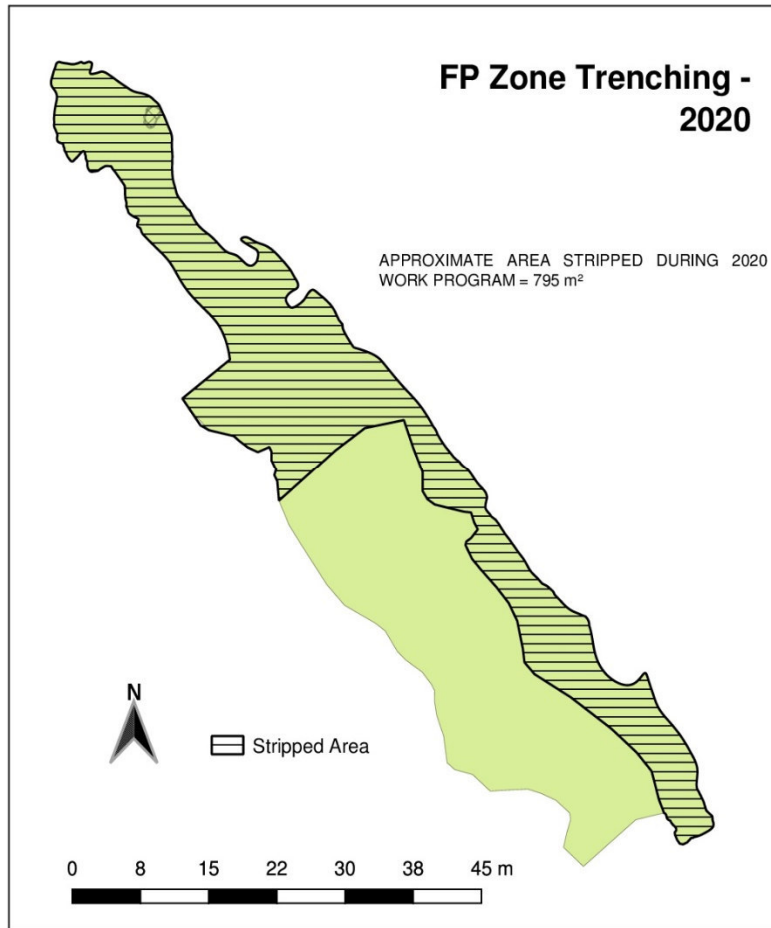

Fig. 3 – 2020 FP Zone Surface Stripping

Channel sampling was carried out in fine weather conditions from June 3 , 2020 to June 15th, 2020. 196 samples were collected for assay from the 37 channels marked. The channel sampling, utilizing a rock saw for cutting and chisels to extract the sample, was conducted by a 2 man crew contracted from Canadian Exploration Services. The 196 samples collected were sent to ALS Canada Ltd for assaying using the Au-ICP21 and ME-ICP41 analytical method. Twenty one control samples comprising blanks and standard were included in the sample shipment.

The bedrock exposed in the majority of the area exhibited a veneer of rubbly, iron oxidation attributed to ankerite alteration and pyritization of the mafic volcanic which masked the unaltered character of the bedrock (see Fig. 8). (See Fig. 3, 4, 5, 7 for an overview of the FP stripping area.) (See Fig. 9 for a drone image of the FP stripping area.) All ground observed was a fine-grained mafic volcanic, typically bleached to a pale grey in colour. Pyrite mineralization was prevalent throughout the stripped area with fine to coarse-grained concentrations up to 15% locally. Narrow quartz stringers

were evident locally throughout the stripped area with no preferred orientation. Locally, the area has a sheared texture. Locally, the mafic volcanic was well jointed. Neither the joints, nor the shearing, have a preferred orientation. Visible gold was found in channel 29. It was associated with quartz stringers. The highest gold grades were found in channels 19, 29, 30, 32, 33, and 34. These grades are associated with quartz-breccia and quartz stringers (see Fig. 9).
