## SUMMARY

This report covers two years (2020-21) of exploration work at the Lilypad Project of Avalon Advanced Materials. The project had been largely dormant since 2001 but renewed activity was driven by new attention towards new possible sources of cesium, which is present at Lilypad in the mineral pollucite.

In 2018 an extremely brief visit was made to the property to assess the status of the historic camp and what would be required to renew the camp for exploration purposes.

The primary objective of the 2020 field work was to collect a mini bulk sample of Cs<sup>1</sup>-bearing pegmatite from the Pollucite Dyke, in addition to sampling other pegmatite localities as time and access allowed. This work was helicopter supported and completed in two days. The historic exploration camp was also visited, to assess the condition and clean-up requirements of tent frames and any drill-related material, and to assess condition of core and core racks stored at the camp.

Twenty-one samples of historic drill core and twenty-three samples of rock outcrop were collected in the 2020 project visit. Twenty-two samples were submitted for laboratory analysis and the remainder were retained for metallurgical testwork. The total cost of the 2020 program was \$47,015.

*Table 1: Total Costs of 2020 Field Program*

Category	Cost	Cost per person/day
1. Labour costs and field supervision - field work	\$ -	\$ -
1. Labour costs and Field Supervision Toronto admin salaries	\$ 7,049.40	\$ 352.47
2. Fees for contractors and consultants	\$ 12,790.75	\$ 639.54
3. Cost of supplies consumed and equipment rental: CAMP SUPPLIES	\$ 327.88	\$ 16.39
4. Cost of food and lodging	\$ 3,088.16	\$ 154.41
5. Cost of transport and travel - equipment and people	\$ 2,746.03	\$ 137.30
Flights (helicopter)	\$ 19,610.00	\$ 980.50
6. Cost of shipping samples	\$ 287.05	\$ 14.35
7. Cost of assays and sample analysis	\$ 1,115.00	\$ 55.75
8. Cost of building trail to site	\$ -	\$ -
9. Industrial mineral marketing	\$ -	\$ -
10. Aboriginal consultation	\$ -	\$ -
<b>TOTAL</b>	<b>\$ 47,014.27</b>	<b>\$ 2,350.71</b>

For the 2021 field program, a camp was established in the same location as for previous work and a field program of approximately four weeks was carried out. The program was completed in two stages with the first in late June and the second in late July. The technical

<sup>1</sup> Elemental symbols are used throughout including Cs for cesium, Ta for tantalum, Li for lithium and K for potassium

work included rock sampling, both regional and localised at showings, soil sampling and biogeochemistry sampling. The rock sampling was coordinated with a mapping program both to bring historic geological maps into current UTM grid systems and also add to the historic mapping. It was supported by camp construction and limited grid establishment and supplied from Armstrong Station by NDK Air using float equipped Otter and Beaver aircraft.

The total number of samples collected in 2021 is given in the table below.

*Table 2: GEOCHEMICAL SAMPLES COLLECTED*

	1st program	2nd program	Total
Soil samples	18	75	94
Biogeochem	270	456	728
Rocks	0	28	28
Water (regional)	9	10	19
Water (camp safety)	12	8	20
Total	288	559	847

Note that not all samples were submitted for analysis so the number collected and number analysed may not be equal in all cases. In some cases, especially vegetation, the laboratory had delays in processing as of the date of this report and 456 results are pending.

The total expenditure for the field program was \$356,000.

## INTRODUCTION

The Lilypad Cesium-Lithium-Tantalum property ("the property") has been owned by Avalon Advanced Materials since 1999. The property is in northern Ontario about 350 kilometres north of Thunder Bay.

Considerable exploration was undertaken between the staking and work in 2001 including geological mapping, geophysical surveys and diamond drilling. The initial work was largely focused on tantalum potential. The property was dormant after 2001. Mineralization was outlined at the Rubellite Dyke, Pollucite Dyke, South Dyke, JJ Dyke, F Anomaly, and C Anomaly among others.

The purpose of this report is to document and discuss the results of the 2021 geological and geochemical field programs, to briefly mention the sample collection in 2020 and to recommend further work on the Lilypad property. The 2021 field programs were carried out under the direction of geologist Sarah Bodeving, supervised by Bill Mercer, VP, Operations, Avalon, at the time of the field program. Sarah Bodeving was assisted by Richard Brett, who completed camp construction and maintenance, as well as members of the Whitesand and Eabametoong First Nations. The work in 2020 was directed in the field by Chris Pedersen, also supervised from the corporate office by Bill Mercer.

The workers at site during the field programs are listed in Table 4 and 5. The working days include travel days.

## **PROPERTY DESCRIPTION AND LOCATION**

The Lilypad Cesium-Lithium-Tantalum property is located in northwestern Ontario, Canada, approximately 20 kilometres west-northwest of the Eabametoong First Nation community of Fort Hope; 85 kilometres east-northeast of Pickle Lake; 160 kilometres north of Armstrong on the CNR mainline; and 350 kilometres north of Thunder Bay (Figure 1).

The NTS reference for the property is 52 P/9, with the approximate geographical centre of the property situated at Latitude 51° 38' N and Longitude 88° 15' W.

Present access to the property is mainly by float or ski-equipped aircraft or helicopter. It is possible to land on Lilypad Lake for planes with STOL capability when the water level is high enough, though late in the summer the water may be too low. At present larger lakes more suitable for float planes are further from the exploration areas and there is no development access such as ATV trails from such lakes to mineralization.

In winter it would be possible to access by snow machine. There is no existing ice road for larger vehicles in winter though it would be possible to build one given suitable weather

conditions. There is a winter road in existence most years that runs south from Landsdowne House to Fort Hope and thus passes within about 20 kilometres of the property.

There is reportedly a “skidder road” to Opakeigen and Eabametoong First Nation (Fort Hope) (Rees, 2001). It is stated that the skidder road passes through the property along the western end of Lilypad Lake and that during winter, equipment can be driven out of Pickle Lake to Fort Hope, and then to Lilypad Lake along this road. At present there is no confirmation as to the condition of the skidder road.

The construction of an all-weather road linking Fort Hope to the south has been under discussion for some twenty years, especially more recently relating to development of the “Ring of Fire” mineral deposits, but no formal construction has commenced to date. However a powerline is in construction to remote First Nations and will likely become the road route by default. The work is part of the Wataynikaneyap Power Transmission Line Project launched in 2015, which will connect remote communities to the grid over an 1,800-kilometre transmission line.

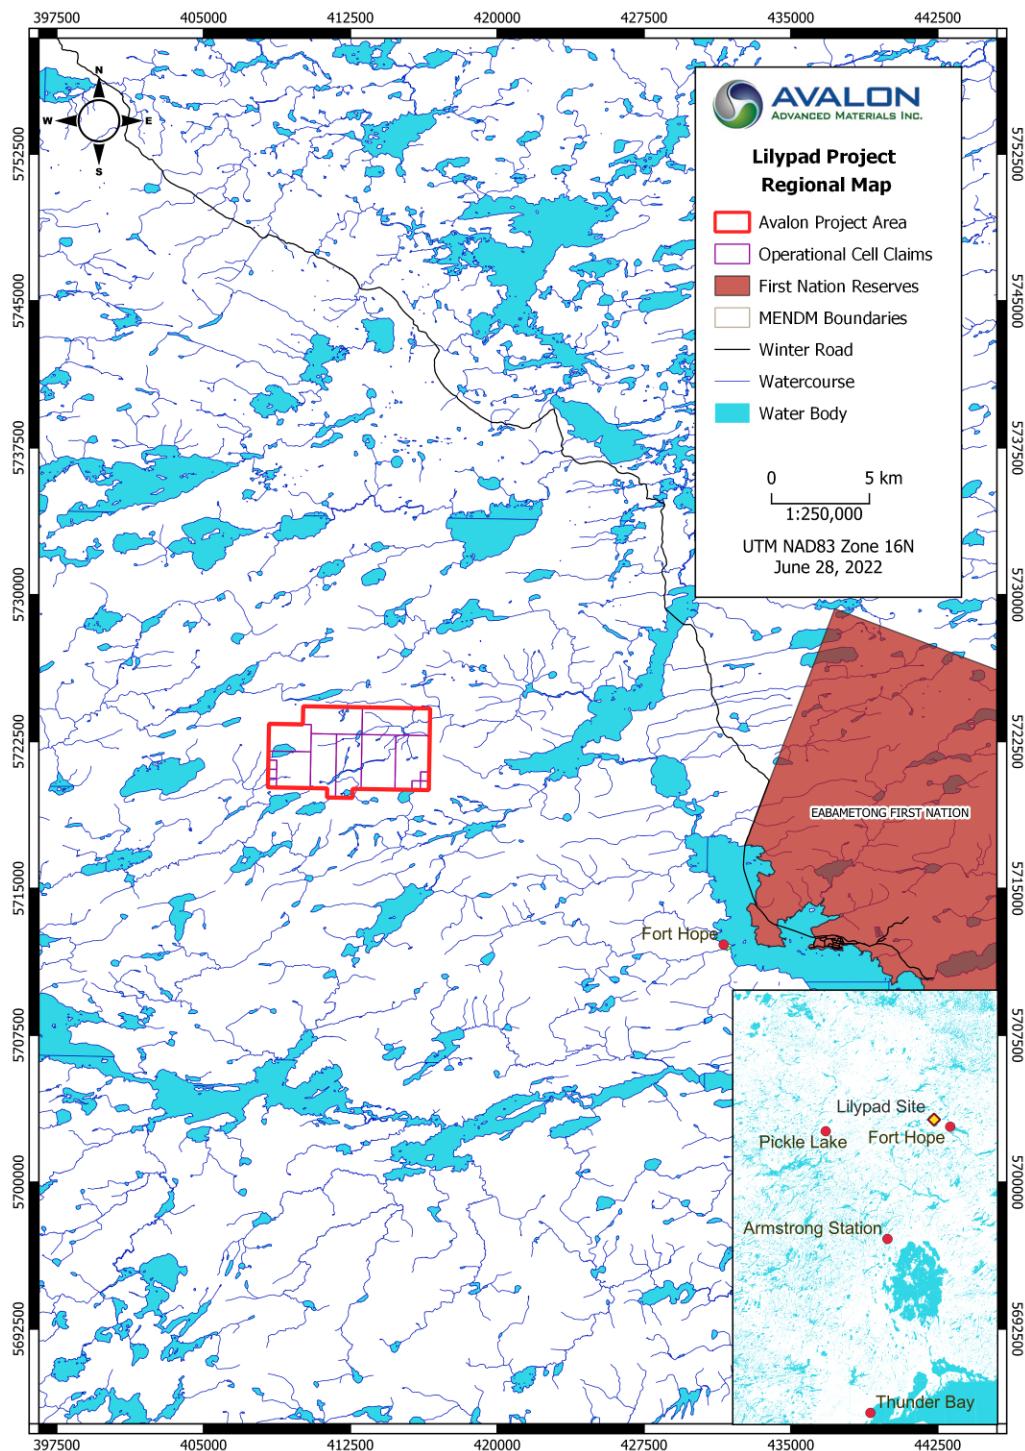

Figure 1: General Location and Access

Avalon has 14 mineral claims at Lilypad Project totalling 166 units covering about 3,330 hectares.

## HISTORY

Rees (2001) has given considerable detail regarding the historic work in the area and this section has considerable material from that publication indicated by italics when a direct quotation.

*Early geological reconnaissance was first carried out by Bell of the Geological Survey of Canada in 1872. This was followed by mapping by Burwash in 1929 and Prest in 1942, both of the Ontario Department of Mines (ODM). Thurston and Carter carried out reconnaissance mapping in the area in 1970 as part of Operation Fort Hope. Wallace (1978) of the Ontario Geological Survey completed the first detailed geology map that includes specifically the Lilypad Lakes pegmatite occurrences.*

There have been a number of Ontario government publications in the period 2004 to 2009 including:

- 2004 Open file 6145 section 8 by L.A.F. Hall describing the geology, including the pegmatites, of the Opikeigen Lake area in the Summary of Field Work and Other Activities, OGS, 2004.
- 2004 Open file 6145 section 11 by Breaks and Tindle describing the geology of the pegmatites of the “Fort Hope Field” (the area referred to by Avalon as the Lilypad project) in the Summary of Field Work and Other Activities, OGS, 2004.
- 2008 Open File 6224 “Reference Specimen Collection of Rare Element Pegmatites, Granitic Rocks and Migmatites from the Superior Province. This includes a few pictures and brief description of government samples from the Lilypad pegmatites.
- 2009 Open File 3611 a geological compilation map that brings together all the historic mapping of the Miminiska Lake – Fort Hope area at 1:250,000. This includes the complete area of the Avalon property.

As Rees (op. cit.) covers industry work in considerable detail, it will be very abbreviated here from that text. The earliest work mentioned is Standard Lithium in 1956, which completed drilling and trenching on the Spodumene and Lepidolite Dykes. This was followed by drilling by R.J. Campbell in 1962.

From 1979 to 1982 Tantalum Mining Corporation completed considerable exploration including lithogeochemistry, geophysics (EM, magnetometer) and diamond drilling (52 holes for 5,367 metres) were apparently targeted on geochemical anomalies. It appears that the company only analysed for Ta and Sn and not for Cs, Rb or Li. Tantalum Corporation allowed the claims to lapse.

In 1987 to 1988 Gold Fields Canadian Mining Ltd restaked the area and explored for gold using geochemistry and analyses for Au and As. Gold Fields did no drilling.

Avalon staked the area in 1999 and did mineral exploration in 1999-2001. Data filed for assessment by Tanco and previous workers was compiled and followed by a preliminary sampling program in September 1999. Subsequently a grid was cut on the property.

A diamond drill program totalling 9 holes for 901m was carried out in March 2000. This program confirmed the continuity of high-grade Ta and Cs mineralization to depth in several of the known pegmatites, including a newly identified high-grade Cs zone at the Pollucite Dyke. In fall 2000, gravity surveying, bedrock lithogeochemical sampling, prospecting, and detailed geological mapping of pegmatite occurrences were completed. Several new pegmatite occurrences were discovered, including the high-grade JJ Dyke.

The field program was followed by 8 drill holes of 1094m in late 2000. The diamond drilling extended the vertical continuity of tantalum mineralization within the Rubellite, South, and Pollucite Dykes, and resulted in the development of an inferred geological resource of 250.000 tonnes grading 0.030%  $Ta_2O_5$ , at the Rubellite Dyke. All work completed by Avalon prior to the current program is documented in Pedersen (2000a, b, c), Morgan and Pedersen (2000) and Rees (2001). In the early work, as the focus was on tantalum potential, less attention was paid to the caesium and lithium mineralization potential.

## REGIONAL GEOLOGY

The Lilypad property is located in the eastern part of the Uchi Subprovince, a 600km long east trending terrane of the Superior Province, composed of interconnected greenstone belts and associated mafic to felsic granitoid suites (Hollings & Kerrich, 2006; Hall, 2004). The Uchi Subprovince is spatially constrained in the north by the plutonic Berens River Subprovince and in the south by the metasediment dominated English River Subprovince (Corfu & Stott, 1996). Between 3 Ga<sup>2</sup> and 2.7 Ga multiple episodes of volcanic activity linked to rifting, arc-magmatism, thrust sedimentation and incremental accretion of new crust to the Uchi-Sachigo microcontinent occurred, terminating in the collision of the latter with the Winnipeg River-Wabigoon terrane during the Kenora orogeny at  $2705 \pm 3$  Ma (Easton, 2000). The metamorphic grade of the belt is low pressure greenschist to amphibolite facies (Easton, 2000).

The Lilypad pegmatites belong to the Fort Hope rare-element pegmatite field and are hosted in the Fort-Hope Miminiska greenstone belt (Černý and Meintzer, 1988; Hall, 2004).

---

<sup>2</sup> Ga refers to billions of years ago and Ma to millions of years

The predominant feature of the belt is a sequence of felsic to mafic intermediate metavolcanics, intercalated with assorted and derived peraluminous metasediments (Taylor, 2005). This complex sequence has been tightly folded into a 13 km wide east-west trending belt bounded by migmatized metasediments and paragneiss to the south, known as the Kawitos Lake Batholith and a circular composite granitoid pluton in the north, known as the Cluff Lake stock. Felsic porphyry dykes and sills intrude the supracrustal rocks across the property and have been interpreted to likely represent associated sub-volcanic intrusives (Taylor, 2005).

The Kawitos Lake batholith is composed of a peraluminous monzonite to granite stock intruded lit par lit into orthogneiss. Wallace (1978, 1981) reports abundant pegmatitic sequences containing muscovite, sillimanite, and staurolite. The Kawitos Lake Batholith is considered to be a possible parental source of the rare metal-enriched pegmatite dykes on the Lilypad property. It has been dated at  $2685 \pm 4$  Ma (U/Pb, Davis & Sutcliffe, 2017) and  $2698 \pm 8$  Ma (U/Pb, Buse & Hamilton, 2012). The Cluff Lake stock is composed of hornblende-biotite granodiorite and tonalite-monzonite.

## PROPERTY GEOLOGY

### Country Rocks

The Lilypad pegmatites are predominately underlain by an east-west trending mafic to felsic metavolcanic sequence. The metavolcanics consist of amphibolite of basaltic to andesitic composition and are characterized in the field by massive to pillow flows, which are locally closely associated with enclaves of Algoma-type iron formations. Tuffaceous felsic volcanics of rhyodacitic to rhyolitic compositions are interlayered with the mafic volcanics (Wallace, 1978). Subvolcanic intrusions of quartz-feldspar porphyry sills and dykes concordantly intruded the metavolcanic sequences (Taylor, 2005). The northern and southern margins of the belt are delineated by migmatized metasediments comprised of sandstones, siltstones, greywacke and polymictic paraconglomerate (Wallace, 1978).

The geology of the Lilypad property is structurally complex, as indicated by the development of strong foliations, local schistosity, major and minor folds, and late-stage brittle faults. The east-west volcanic stratigraphy was deformed as part of a larger-scale east-west trending folding episode (Wallace, 1978, op. cit.). Disjointed and laterally discontinuous iron formation horizons, as well as the development of small-scale pinch-and-swell structures (boudins) indicate that the rocks were subjected to east-west extensional deformation.

At least three north-south trending transverse faults pass through the Lilypad property, two of which extend into the Kawitos Lake Batholith to the south. Assuming that these faults represent syn-intrusive structures, they may have played a role in the migration of volatile-rich residual melts from the Kawitos Lake Batholith and subsequent pegmatite emplacement (Rees, 2001). Locally Z-, S- or M-shaped tight isoclinal folds can be observed in the pegmatites and host rocks and sinistral offset is common.

The rock package of the belt has been subject to almandine amphibolite facies metamorphism, with locally occurring retrograde greenschist facies (Wallace, 1978).

## Pegmatites

The discovered pegmatites so far at Lilypad extend over an area of approximately 2 x 6km. Individual dykes range from a few cm to up to several tens of metres width and can be locally traced up to 750m along strike. The steep dipping dykes show a general trend of 240°-270°, with a few exceptions (i.e., Rubellite Dyke and South Dyke). *The main portions of these dykes trend approximately north-south, crosscutting the host stratigraphy at high angles. Diamond drilling indicates that the dykes are continuous to depth, with little change in morphology or mineralogy* (Rees, 2001). Breaks and Tindle (2004) identified four different types of pegmatites at Lilypad, based on the classification scheme of Cerny (1991): albite spodumene; complex spodumene; complex elbaite; and albite. All of the pegmatites exhibit a high degree of fractionation and are considered some of the most evolved rocks in North America, due to the occurrence of pollucite, a rare cesium mineral and rubellite, an elbaite tourmaline mineral (Breaks & Tindle, 2004).

## FALL 2020 SURFACE PROGRAM

Two days, from October 1-2, were spent on site, collecting rock samples, two mini-bulk samples, and examining and collecting historic pegmatite drill core. Access to the site and the pegmatite occurrences was by helicopter, from O'Sullivan's Rainbow Lodge north of Nakina. Personnel for the field program were JC Pedersen (field supervisor), Sarah Bodeving, and Richard Brett. The program was supervised from Toronto by Bill Mercer (VP, Operations).

### Discussion

The historic exploration camp was visited on the first field day in order to determine the condition of the historic drill core stored at site, and to assess the general state of the remains of the camp.

Tents and equipment have been removed from the site, with wooden tent frames partially standing to completely collapsed. Several bins containing scrap metal and drill parts were documented adjacent to the historic disposal pit on the west side of camp.

Core racks have collapsed (Figure 3), but with core boxes generally intact in telescoped positions. Some core boxes are decomposing, and numerous boxes of core may not be salvageable. Several cross-stacked columns of core boxes contain only country rock, with little or no pegmatite. In the telescoped core racks, only two intersections of pegmatite remain, one each from the Pollucite and Rubellite Dykes. Only the Rubellite Dyke core was sampled, as it was the most accessible, and labelled for proper identification. Twenty-two (22) core samples were collected for both thin section, microprobe, and geochemical analyses.

Figure 3: Collapsed Core Racks and Sampling Pegmatite

Of the three pegmatites visited, only the Spodumene Dyke was not sampled. A traverse from the historic exploration camp to the dyke located the pegmatite outcrops, but not the historic trenches. The smooth whale-back outcrops did not allow for easy sampling, and without locating the historic trenches, no sampling was performed.

## Pollucite Dyke

The Pollucite Dyke is a complex-type, albite-spodumene-lepidolite sub-type rare-element class pegmatite. Previous drilling has produced an historic resource estimate of 340,000 tonnes grading 2.294% Cs<sub>2</sub>O and 0.037% Ta<sub>2</sub>O<sub>5</sub> (this resources estimate has not been assessed by a Qualified Person and was not completed under NI 43-101 conditions). The pegmatite is open along strike and to depth.

Figure 4: Pollucite Dyke

The Pollucite Dyke was sampled in the 2020 program from an historic trench (Figs. 4,5,6) on the main outcropping of the dyke. The trench is centred on NAD 27 411597E 5722554W.

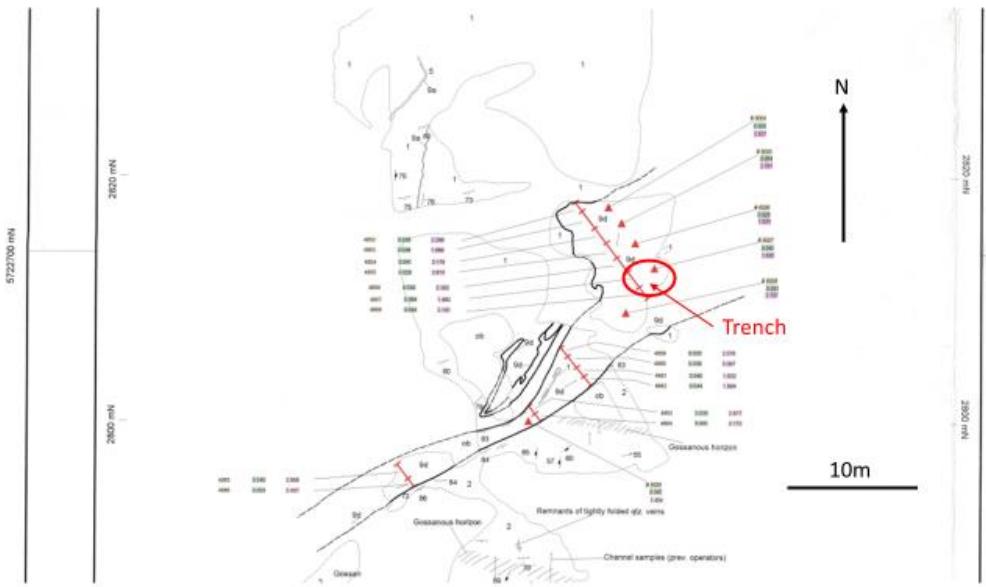

Figure 5: Copy of Historic Map of Pollucite Dyke with Trench Location (Rees, 2001)

A total of 247 kgs of sample was collected from the trench in hand-sized pieces. This “mini bulk sample” was collected for analytical verification of Cs grades and for preliminary metallurgical testwork for concentrating pollucite.

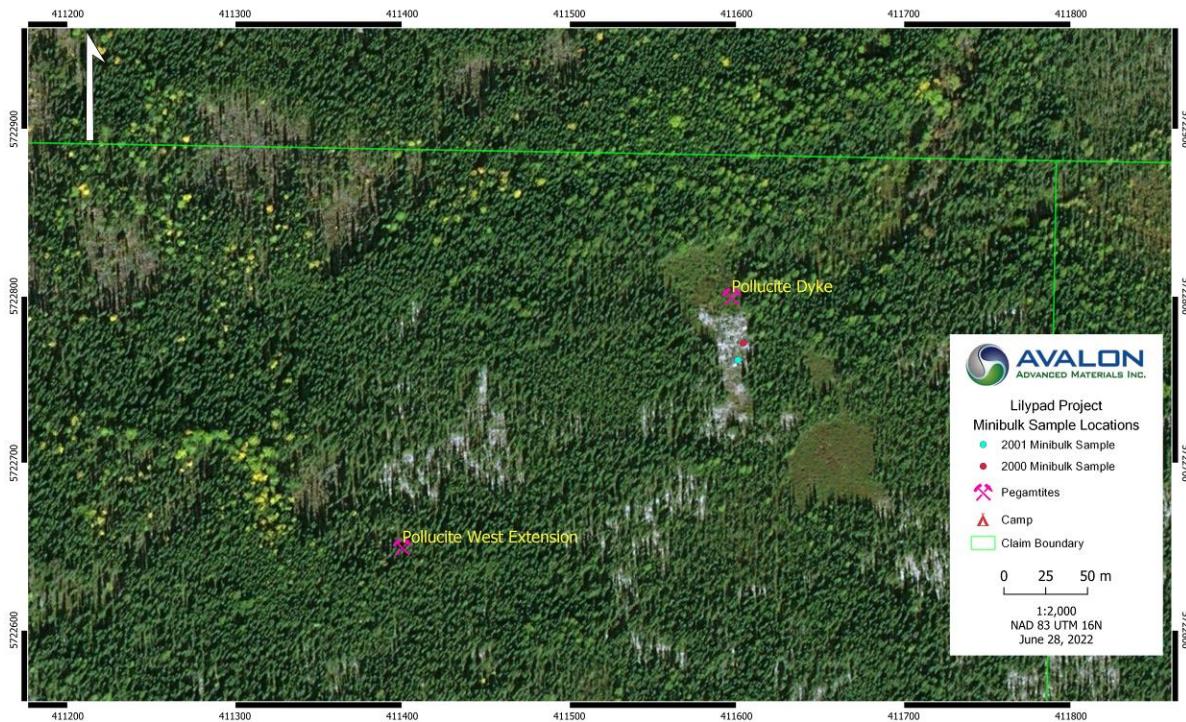

Figure 6: Location of Minibulk Samples 2020 and 2021:

The samples, in rice bags, were flown by helicopter from site to the base at O'Sullivan's Lodge, and from there transported by truck to a secure storage facility in Kenora.

## Rubellite Dyke

The Rubellite Dyke is located 2.5 kms east of the Pollucite Dyke. The dyke is centred at NAD 27 414085E 5722375N. Two historic trenches were sampled in the current program (Figure 8), one on the north outcrop and one on the south outcrop:

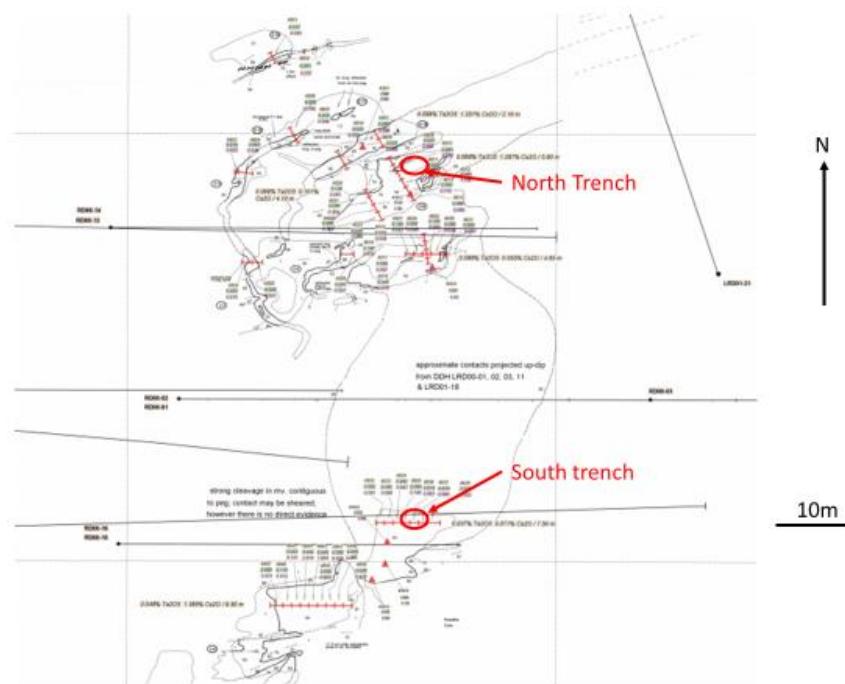

Figure 7: Copy of Historic Map of Rubellite Dyke with Trench Location (Rees 2001)

The Rubellite Dyke (Figure 9,10) is open to depth at 250m and contains both Cs, Li and Ta enrichment. Tantalum analyses up to 0.10%  $Ta_2O_5$  have been historically documented. Pollucite also occurs in enriched zones throughout the pegmatite; historic surface channel samples from the north and south outcrops grade 1.287%  $Cs_2O/5.8m$  and 1.385%  $Cs_2O/9.5m$  respectively.

Figure 8: Rubellite Dyke Looking toward North

Figure 9: Rubellite Dyke, N and S Outcrops

The North Trench (Figure 10) is centred at NAD27 414094E 5722408N. A 50kg sample was collected from this trench for future analytical and metallurgical testing. Samples were collected by hand and averaged from hand-sized to 20cm in diameter.

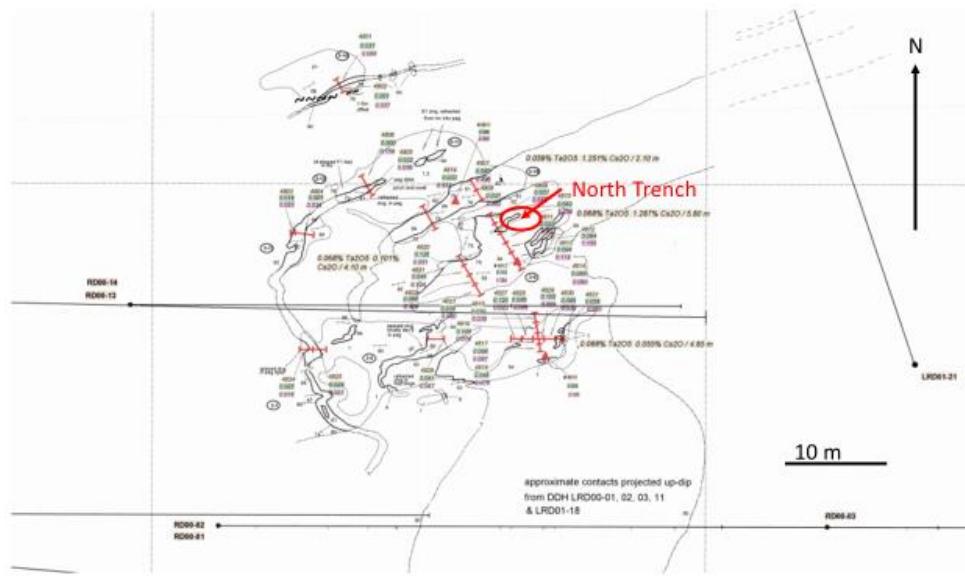

Figure 10: Copy of Detail of Historic Map of Rubellite Dyke North Outcrop and Trench (Rees, 2001)

The South Trench (Figure 12) is centred at NAD27 414081E 5722364N. A 50kg sample was also collected from this trench for future analytical and metallurgical testing. Samples were collected by hand and averaged from hand-sized to 20cm in diameter.

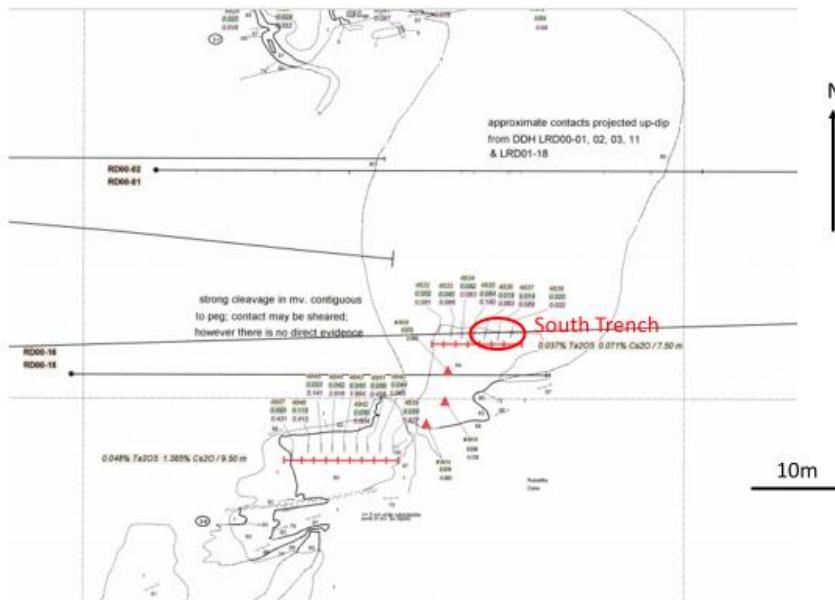

Figure 11: Copy of Detail of Historic Map of Rubellite Dyke South Trench (Rees, 2001)

Samples, in rice bags, from both trenches were flown to the base at O'Sullivan's Lodge along with Pollucite Dyke samples. From there they were trucked to East Selkirk, Manitoba, where they are in secure storage pending testwork requirements.

## **SUMMER 2021 SURFACE PROGRAM**

The summer 2021 Lilypad program ran from June 21<sup>st</sup> to July 9<sup>th</sup> and from July 26<sup>th</sup> to August 8<sup>th</sup>. An additional flight was completed August 15<sup>th</sup> to ensure the camp was correctly closed and to remove the last load of equipment. The field program consisted of building a base camp, collecting biogeochemistry, water and soil samples, an additional mini bulk sample from the Pollucite Dyke, prospecting, lithogeochemical sampling and other geological work.

Material left at the camp from historic exploration was cleaned up. This comprised wood that could be disposed of at site and metal drill parts in drums. All the metal garbage was flown out and disposed of appropriately at the Armstrong Station Landfill Facility about 6 kms east of the community of Armstrong Station. It was estimated by the air charter company that the total weight of material flown out was around 1 tonne.

Personnel for the field program were Sarah Bodeving (senior geologist,) Richard Brett (camp manager, sampling crew, prospector), Ragi Ramesh (junior geologist), Barbara Dupuis (cook), Pius Legarde (line cutter/sampling crew), Bill Spade (line cutter), Kirk Kokokons (line cutter/sampling crew), Kelvin Kwadibens (line cutter/sampling crew), Tyrese Whitehead (sampling crew), Josh Shapwaykeesic (line cutter/sampling crew), Conway Nodin (line cutter), Andrew Waboose (manual labour). Some workers were employees and some on contract including those for the line cutting. Indigenous workers comprised 75% of those on site over the complete program.

Access to the camp was by float plane with NDK Air based in Armstrong Station, Ontario. Initially lumber and other materials were flown in by float plane with NDK Air from Pickle Lake and Armstrong Station, Ontario. Subsequent supply and mobilization were via Armstrong Station. NDK Air also provided excellent expediting and other services out of Thunder Bay.

The field work was carried out mainly on foot except for some remote access by aircraft. Access to the eastern part of the claims was assisted by canoe or a small motor-powered boat on Lilypad Creek.

### **Camp Establishment**

There was no usable camp remaining from previous work. As a result, a new camp was established suitable for a crew of about five to ten people (Figure 12). The main work incurred was:

- Building a new dock on Lilypad Lake suitable for float plane access
- Erecting four canvas tents on plywood floors as well as two toilets and a shower
- Clear cutting a helicopter landing pad
- Provision of satellite communications for regular and emergency use
- Removal of waste materials from historic exploration activities
- Flying in of core racks and core boxes

The camp's water supply was mainly provided by Lilypad Lake. In order to guarantee the safety of the water, a MP4U Gravity Water Filter from Rainfresh Water Filters was used. Samples of the purified water were taken at regular intervals and sent to the ALS laboratory in Thunder Bay for E. coli testing.

A water purifying system was installed in the Lilypad project camp in order to provide safe water for drinking. The work period in the summer had numerous long days with high temperatures day and night so safe water was essential for the crew. The water purifying system was a supplement to water flown into the camp sourced in large bottles from grocery stores and large containers from a domestic water well in Armstrong Station.

The equipment used in the camp was a Rainfresh Gravity Water Filter System MP4U. This comprises a plastic double bucket system with a filter system that is rated to remove E. coli which are 0.5 by  $2\mu$  and so is also assumed to remove giardia which are 7 by  $15\mu$ . It can process 25 litres in 8 hours (2.9 litres/hour). A program of analysis of the lake water provided to the purifier and the water exiting the purifier was implemented in order to monitor the performance of the purifier. The point about the size of giardia and E. coli is important because E. coli analyses were available but not giardia analyses so it could be proven whether E. coli are removed but not giardia.

Five test sequences were completed with each test during the periodic cleaning of the filter system. The usual method was to collect two samples of lake water prior to introduction to the filter and then two filtered samples. Some checks were included with Armstrong well water and bottled water from the grocery store. The water samples were analysed in the ALS Environmental Laboratory in Thunder Bay which laboratory also provided the specific required sample bottles and instructions.

The results are summarized in Table 7 below. The analyses demonstrated that the filter removed the E. coli and fecal coliforms from the lake water, in both cases to zero measurement. There were two anomalies in Total Coliforms which bias the mean to 484. Without those biased samples the mean total coliforms would be 0.25, or 2000 times lower and lower than the well water. The two high total coliform analyses, higher than the lake

water starting point, could be contamination introduced during the filter cleaning process or a lab error, but there is no way to confirm either possibility. (NOTE: MPN is Most Probable Number and is the count of, for example, bacteria for the purposes of human health). Total Coliforms excluding e coli are unlikely to cause human health problems.

*Table 7: Biological Analyses of Lake and Filter Water, Lilypad Camp, 2021 (MPN/100 ml)*

MPN/100mL or CFU/ml (HPC)	Number of analyses	Escherichia Coli	Fecal coliforms	Total Coliforms #	Heterotrophic Plate Count
Armstrong well water	2	0	0	6	300
Filtered Water	10	0	0	484	300
Lake Water	8	9	5	419	155
Average of all samples	20	4	2	410	245
	# Average for filtered water affected by two very high analyses (2420)				
	Average = 0.25 without these two analyses				

It was concluded from the testwork that the Rainfresh filter provided water at the camp safe for drinking and other purposes. Note that the filter system would not change the colour of water, so if it was, for example, brown due to dissolved chemicals or elements, that would not change. These observations are in complete agreement with information provided by the manufacturer and CSA Group certification. CSA and manufacturer data indicates total removal of E. coli, typhoid bacteria, cholera bacteria, dysentery bacteria, pneumonia/meningitis bacteria and giardia.

*Figure 12: Camp at Lilypad Lake 411757E 5720771N (NAD83)*

## Line Cutting

Line cutting was carried out by a contractor over a duration of 16 days for a total length of 10.215km (Figure 13). Two North-South and two East-West trending lines were cut to be used as baselines for soil and biochemical sampling lines. Additionally, a trail for easier access to the northern pegmatite showings was cut and flagged. One to two crews, at various times, of 2-3 people worked on the line cutting, using a chainsaw, ax, chain, compass and GPS. The approximately 1.5m wide lines were picketed and flagged at 25m intervals.

*Table 8: Line Cutting Details*

		Easting	Northing	Length
Line 1	North end	411600	5723000	2,168m

## Geological Work and Lithogeochemistry

### Description of Pegmatite Occurrences and Sampling

Most of the known pegmatite occurrences on the Lilypad claims were identified and extensively mapped during the 2000-2001 geological mapping and sampling program.

During the summer 2021 program, six pegmatite occurrences were revisited (E Anomaly/Pollucite Dyke, Rubellite Dyke, Baseline Dyke, Opie Dyke, Spodumene Dyke and F Anomaly) on eight days in order to review the geological maps produced during the 2001 mapping program, to identify the location of historic drill collars by GPS, to sample potentially pollucite-bearing zones and to prospect beyond the currently known pegmatite occurrences.

The following sections discuss each of the Lilypad pegmatite occurrences that were investigated during the 2021 surface program. Additional information with detailed

descriptions and maps regarding the occurrences can be found in previous reports by Morgan and Pedersen (2000), Pedersen (2000a, b) and Rees (2001).

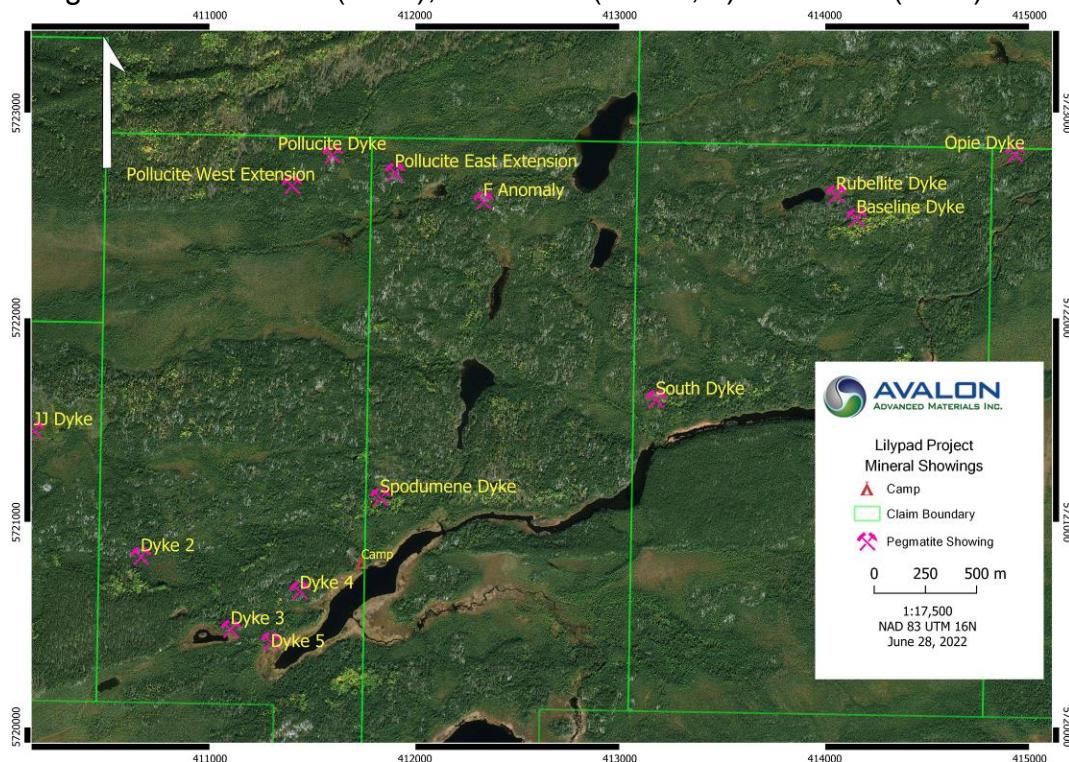

Figure 14: Location of Pegmatite Deposits and Occurrences

## E Anomaly / Pollucite Dyke

The E Anomaly/Pollucite Dyke pegmatite zone consists of a series of boudinaged, disjointed or folded dykes cropping out over a strike length of roughly 500m in the northern part of the claim group. The pegmatites can be subdivided into a southwestern extension, a main showing and an eastern extension.

The main showing (Pollucite Dyke) is composed of a thickened S-folded hinge and consists of a 1.5 to 13m wide and roughly 30m long outcrop entering overburden on either end. It has been previously channel sampled and a blast trench was done on the eastern end of the main dyke. The intrusive contacts with the host rock are characterized by a sharp lithological change generally accompanied by a black or blue coloured metasomatic alteration halo bleeding into the exocontact. Mineralogically the main mass appears unzoned. Intensive hydrothermal overprint eradicated most of the primary textures, creating a schlieren-flaser texture mostly visible by elongated ribbony quartz pods rimmed by anastomising stringers of white pollucite and purple lepidolite (Figure 16). Pollucite additionally occurs as monomineralic anhedral masses in a matrix of white saccharoidal albite. Blades of white angular spodumene are common. Rubellite occurs sporadically.

The southwestern extension of the Pollucite Dyke is characterized by a swarm of dykes ranging from a few cm to up to 3m thickness and variable mineralogy. The swarm can be traced for about 200m, before it disappears underneath the esker and heavy blow down.

The last exposure of the pegmatite swarm at UTM 0411406E 5722666N consists of four dykes trending 11, 12 and 40 strike with a subvertical dip. One of the dykes shows a 20cm slip fault move to the west (disjointed and displaced), visible by the displaced dark tourmaline contact zone and the lack of alteration along fault contact (Figure 15). Mineralogically, the last exposure outcrop is also of importance as pollucite, rubellite and lepidolite are clearly present, while the thinner albite dykes of the swarm macroscopically do not contain rubellite or lepidolite. A very pronounced flaser texture is visible by quartz ridges occurring almost perpendicular to the contact subparallel to the regional foliation (Figure 15). Heavily metasomatized mafic enclaves with drawn out flame texture are sporadically present (Figure 16). One composite sample composed of pieces from two dykes and chips from a channel was taken at this location.

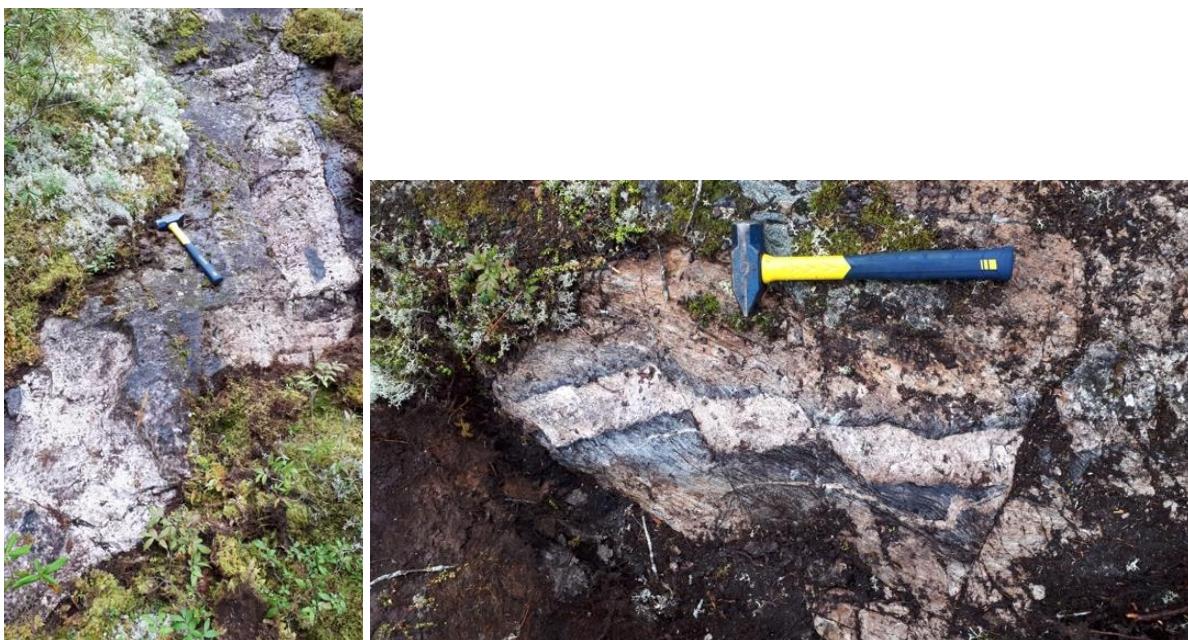

Figure 15: 20 cm displacement visible in last dyke exposure. Disjointed albite dyke. Note metasomatic alteration composed of black tourmaline in exocontact.

Figure 16: Saccharoidal white albite dyke with ribbon elongate quartz, crosscut by white and purple veinlets of pollucite and lepidolite.

Figure 17: Rubellite laths in Pegmatite Dyke

Figure 18: Heavily metasomatized mafic enclave with flame structure in pegmatite

About 25m after the last in situ outcrop exposure (UTM 0411383E 5722651N) of the Pollucite Dyke a large “boulder” of pegmatite in contact with host rock was found in the ground underneath a toppled tree in the esker. The contact remains intact and the rock is

angular, suggesting it has not been transported very far (Figure 19). The rock consists of white pollucite, albite, quartz, purple lepidolite stringers, prisms of pink rubellite and drawn out ribbony quartz. A grab sample was taken. Prospecting was conducted on strike and the surroundings for several hundred metres after the last *in situ* exposure, but no further pegmatite was discovered.

Figure 19: Contact between pegmatite and host rock - considered not "in situ" (left). Contains rubellite, pollucite and lepidolite (right)

The eastern extension of the Pollucite Dyke consists of a swarm of albitic pegmatite dykes ranging in size from a few cm to a thicker dyke showing of a few metres (Figure 18). These dykes do not show macroscopically recognizable pollucite and are mainly composed of quartz and albite. The contact with the host rock is sharp and crosscuts the foliation at a steep angle. Tourmalinization borders are thick in the exocontact. Locally tourmaline crystals grow into the endocontact. The dykes exhibit a “wiggly” curved shape and seem to be trending mostly between 200° and 240° however do get deflected into other directions. A composite grab sample composed of several pieces from three individual smaller albitite dykes was collected at UTM 0411698E 5722578N.

At UTM 0411902E 5722715N a dyke of 1.5m thickness was encountered cropping out along the edge of an amphibolite cliff. This dyke may potentially contain pollucite and exhibits the typical “flaser texture” observed at the main Pollucite Dyke showing and seems to be less albitic than most other dykes in the eastern extension. A surface grab sample (Sample 718516) was taken, visually considered to contain albitite, fluorite, lepidolite and potentially pollucite. However on analysis it showed slightly anomalous Cs (250ppm) and Rb (1495ppm) but insignificant Ta and Li.

Generally, the eastern extension pegmatite zone consists of albitic dykes showcasing a lack of lepidolite, pollucite or rubellite, whereas the southwestern extension exhibits a mineralogy similar to the main pegmatite mass at the Pollucite Dyke.

*Figure 20: Parallel albite dykes in eastern extension zone*

The location of eight historic drill sites representing twelve drill holes was recorded by GPS and compared to old maps from the 2000-2001 programs. The tables below give the field data from 2021 and a comparison to the data in the Avalon digital drill database. The drill database is in NAD27 and the 2021 surveying was in NAD83. In the second table the NAD83 (2021) coordinates are converted to NAD27 using the Canadian government online NAD83/27 converter. The resultant average difference in Easting is 5.7 metres and in Northing 1.1 metres, which are negligible errors on a percentage basis given the use of handheld GPS. As a result, it can be considered that the drill database has been validated.

## Spodumene Dyke

The Spodumene Dyke showing is located at UTM 0411809E 5721127N, and consists of a series of approximately east-west trending dykes and stringers cropping out as pinch and swells over an area of 100m.

Previous programs noted that the Spodumene Dyke appears to have undergone greater deformation than the other pegmatites on the claims and exhibits a very different mineralogy than all the other pegmatite occurrences. Rees (2001) described two different mineralogical types of dykes: A more ‘primary’ granitic variety, characterized by salmon-pink K-feldspar and green spodumene crystals up to 20 centimetres long, along with lesser albite, grey quartz, minor green mica, and garnet. The second, more commonly seen phase appears to be a highly albited version of the first. This variety also contains abundant green spodumene, but with white albite (cleavelandite) replacing the K-feldspar. Green mica appears to constitute a larger percentage of these dykes as compared to the ‘primary’ variety, whereas grey quartz is present in similar amounts. Garnet and blue apatite aggregates also occur more commonly, often in association with each other, although still in minor amounts. Small black to reddish-brown opaques, at least some of which are tantalum oxides, seem to be much more common in the albited variety, occurring most frequently within the albitic ground mass and along crystal faces of the spodumene.

Detailed mineralogical observations across the strike of the dykes, shows that individual dykes contain both varieties. Commonly, a more albitic pinkish phase is found close to the contact with the host rock and then slowly grading into a coarser zone with cm size K-feldspar and coarse, but smaller sized seagreen spodumene. This is well observable in the main mass of the Spodumene Dyke outcrop. The contact is sharp, with a darker alteration halo of up to 10cm, with layers in the host rock changing between brown and black, with the black being composed of tourmaline. In certain contact locations, black euhedral tourmaline of 2-3mm size is also observed in the endocontact. The endocontact seems to have a 1cm rind of pure albite with no quartz present before grading into an albite zone with smaller grains of quartz. The quartz texture is oftentimes similar looking to the Pollucite dyke flaser – schlieren texture. Deformation is visible in the dykes in the form of rotated crystal cleavages. K-feldspar is commonly perfectly euhedral with up to 20cm size white crystals locally exhibiting graphic textures. Spodumene is present as euhedral prisms of up to 20cm size, often of a seagreen color and a distinctive cleavage (Figure 19). Generally, the center of the dykes is coarser grained and composed of K-feldspar and spodumene, coated with long stringers of interstitial grey, glassy quartz and milk white albite. In the albitized zones of the dykes, K-feldspar is replaced by albite.

Eight lithogeochemical surface grab samples were collected along strike representing both types of dyke varieties (Appendix 1). One sample originates from the historic blast trench at UTM 0411793E 5721153N and contains coarse spodumene rimmed with black/greenish mica, very coarse-grained K-feldspar, blue apatite, sporadic red garnet and black oxides in a quartz feldspar matrix. A second sample was collected at the main dyke exposure at UTM 0411809E 5721127N composed of saccharoidal albite with green mica. Five additional samples were taken on strike along boudins of the main pegmatite dyke cropping out along a ridge in a birch forest. They were mainly composed of white saccharoidal albite locally containing seagreen spodumene, green mica and salmon coloured K-feldspar. One sample was taken at an outcrop in the swamp (UTM 0411829E 5721151N) composed of coarse grained crystals of K-feldspar and spodumene coated with quartz in an albite and green mica matrix.

The historic drill collars at the Spodumene Dyke could not be located due to dense vegetation.

Figure 21: Seagreen spodumene coated by green mica in albite and quartz (left). 15 cm long spodumene rimmed by mica associated with pink K-spar (right)

## Rubellite Dyke

The Rubellite Dyke pegmatite zone is located in the northwestern part of the Lilypad claim group and is composed of a series of steeply dipping exotic looking dykes exhibiting a variety of fold morphologies (S-, M- and Z-) and related pressure shadow zones (Barclay, 2001). The main Rubellite Dyke is exposed over a strike length of 115m averaging about 7m in width. It is separated into a northern and southern exposure divided by a 35m wide spruce bog (Rees, 2001). The intrusive contact with the mafic host rock is sharp and locally exhibits a black to blue 2-10cm thick metasomatic alteration zone composed of prisms of holmquistite and tourmaline. In the Northern exposure extremely coarse grained white spodumene occurs together with blocky black to salmon coloured K-feldspar and monomineralic pods of quartz (Figure 22). Laths of pink rubellite are hosted in a groundmass of white to bluish albite. Crosscutting stringers of purple lepidolite and a white phase (pollucite?) are common. Some zones have undergone intense alteration characterized by green clay replacement of spodumene. Late fractures are filled with beige/salmon coloured potential amblygonite and bavenite and pods of deep purple fluorite.

The Southern exposure is mineralogically similar to the Northern exposure, however exhibiting a higher concentration of rubellite and a less coarse-grained blocky texture. The up to several cm long rubellite blades occur subparallel to white laths of spodumene hosted in a matrix of saccharoidal albite (Figure 23).

Three surface grab samples were collected at the Southern exposure (UTM 0414080E 5722581N) for lithogeochemical analyses to identify the presence of pollucite.

The location of 6 historic drill collars was recorded by GPS and compared to old maps from the 2000-2001 programs (see Tables 9 and 10).

Figure 22: Northern exposure. Extremely Blocky spodumene and K-spar (left). Green clay altered spodumene and salmon coloured bavenite (right)

Figure 23: Southern Exposure. Subparallel laths of white spodumene and pink rubellite (left). Coarse white spodumene crystal in groundmass of albite cut by lepidolite and pollucite stringers. Pink rubellite blades and quartz visible. (right)

## Baseline Dyke

The Baseline Dyke is located at UTM 0414155E 5722491N approximately 90 metres SSE of the Rubellite Dyke. Similar to the Southern limb of the Rubellite Dyke, the Baseline Dyke exhibits S-fold morphology. The dyke is hosted in andesitic tuff and is exposed over a length of 25m with a width of up to 4m. The dyke has a similar appearance to the Rubellite Dyke and Barclay (2001) interprets the Baseline Dyke to be a subparallel, en echelon-type dyke to the latter. Compositinally it is mainly comprised of centimetre sized prisms of pink rubellite, stringers of purple lepidolite and a white phase potentially composed of pollucite and creamy to dark grey feldspar hosted in a white matrix mainly comprised of saccharoidal albite and some quartz.

Two surface grab samples (718522, 718523) were taken at the Baseline Dyke at UTM 0414155E 5722491N and UTM 0414161E 5722539N. One sample contained rubellite and lepidolite, whereas the second sample represented a less fractionated zone of the outcrop with little to no rubellite or lepidolite. The analyses (Appendix 2) show that the samples are anomalous and worthy of further investigation.

*Table 11: Analyses of Baseline Dyke Samples*

Sample	Cs <sub>2</sub> O	Rb <sub>2</sub> O	Ta <sub>2</sub> O <sub>5</sub>	Li <sub>2</sub> O
	(%)			
718522	0.073	0.529	0.049	0.403
718523	0.538	0.556	0.055	0.357

## Opie Dyke

The Opie Dyke, located at UTM 0414927E 5722804N, was first discovered during the 2001 program occurring to the east of the Rubellite Dyke. It represents the furthest known eastern extension of the pegmatite zone of Lilypad Lakes. The skinny pegmatite dyke is located in a dense swamp and crops out over a strike length of less than 10 metres trending 259° with a subvertical dip. The width varies between 10 and 35cm. The sharp contact with the host rock is exposed on both sides and shows a <5cm thick metasomatic dark/blueish halo most likely composed of holmquistite and potentially tourmaline. The endocontact is characterized by a white color and locally coarse pink rubellite crystals growing in fans nucleating from the pegmatite wall (Figure 21). Some zones of the albitic dyke are more quartz rich and accessory purple lepidolite is present. A lithogeochemical grab sample was taken at UTM 0414927E 5722804N composed mainly of albite and some lepidolite. No rubellite was present in the sample. No pollucite was macroscopically identified.

Southward of the Opie Dyke along the edge of the swamp an outcrop hosting a squiggly 20 to 30cm long quartz vein with green mica, is exposed in a cliff face. A surface grab sample was collected at UTM 0415106 5722773 (718524) and indicated anomalous Ta<sub>2</sub>O<sub>5</sub> (0.14%), Rb<sub>2</sub>O (0.86%) and Li<sub>2</sub>O (0.27%).

*Figure 24: Contact Zone of Opie Dyke. Pink rubellite nucleating at metasomatized contact zone*

## **F Anomaly**

The F Anomaly consists of a series of variably oriented pegmatites, located approximately 750m south-east of the E Anomaly/Pollucite Dyke. Mineralogically the pegmatite dykes are mostly similar to the Rubellite Dyke in as they contain a matrix of white saccharoidal albite, hosting several mm long pink rubellite crystals, prisms of white spodumene, stringers of purple lepidolite and green mica, quartz pods as well as coarser blocky K-feldspar. Some of the dykes have been previously described as similar to the E Anomaly/Pollucite Dyke containing pollucite. The dykes vary in orientation from northwest-southeast to east and west and are hosted in metasediments and QFP country rock. Two surface grab samples were collected for lithogeochemical analyses at UTM 0412334 5722574 and 0412282 5722471 (718520 and 718521 respectively). One sample consisted of chips from a previous channel cutting through an albite dyke comprising quartz and green mica. The second sample is a grab sample from a less than 1m wide albite dyke with lepidolite and potentially pollucite and rubellite. Analyses (Appendix 2) showed high Ta<sub>2</sub>O<sub>5</sub> (0.12% and 0.10%) but insignificant Cs and Li.

## **Prospecting**

Prospecting was carried out by Richard Brett during two days in an area southwest of Lilypad camp targeting unexplained high lithogeochemistry anomalies from the 2000-2001 sampling programs. A total of 7 grab samples of pegmatitic rock were collected. At the anomalous target points discrete dykes of up to a few cm in width were identified hosting green mica, albite, quartz and locally disseminated cubic oxides and accessory blue apatite.

Further prospecting of one day was carried out by Sarah Bodeving to the east of the E Anomaly in an area with high Li, Cs and Rb anomalies discovered in the 2001 lithogeochemical sampling program. The area immediately west of a large lake is composed of large outcrops of mafic country rock. Two less than 20cm wide white dyklets were discovered parallel to the foliation of the host rock (UTM 0412787E 5722788N). They crop out over a distance of 15m. Mineralogically they seem to be composed mainly of white saccharoidal albite and some quartz. No lepidolite, rubellite or pollucite was detected. No sample was taken at this location due to the polished nature of the rock surface.

## **Description of Lithogeochemistry Sampling Methods**

A total of 28 surface grab samples were collected of which a subset of 26 were sent to the ALS laboratory in Thunder Bay for whole rock assays. Where possible one half of the sample was kept for future analyses and petrographic work and was sent to McGill University in Montreal, Quebec. The samples were bagged together with a laboratory ID which was additionally marked on the sample bag. The samples were flown out in rice bags

from Lilypad camp to Armstrong Station by float plane and subsequently transported by truck to ALS labs in Thunder Bay. The size of the samples averaged 1kg. The aim was to identify the presence of potentially economic grades of specifically cesium, lithium and tantalum.

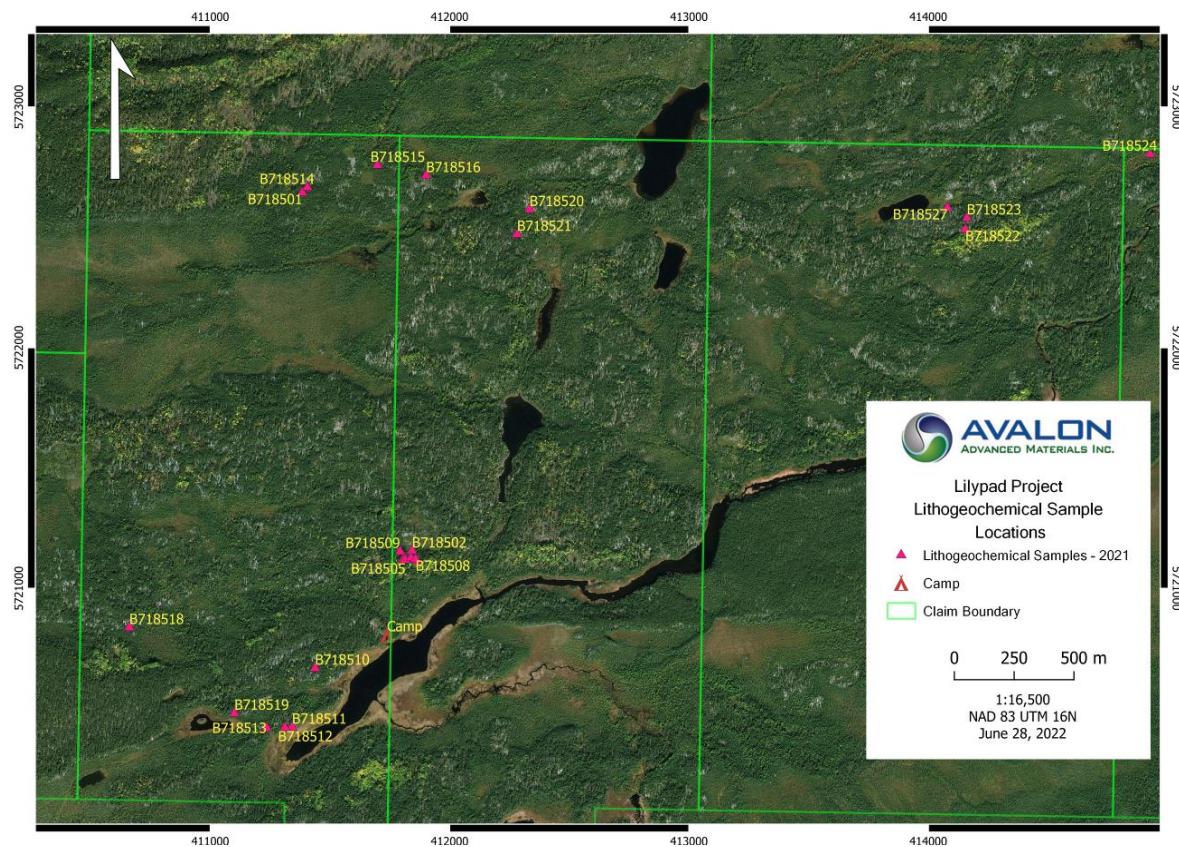

Figure 25: Lithogeochemical Sample Locations

Rock samples were prepared with method PREP-31Y and analysed by code CCP-PKG01. The methods can be summarized as:

1. Prep-31Y: crush to 70% <2mm, pulverize split to >85% passing 75 microns
2. CCP-PKG01 comprises five sets of analyses of over 50 elements:
  - a. ME-ICP06 – whole rock analysis 14 parameters
  - b. ME-IR08 – providing C and S values
  - c. ME-MS81 – fusion followed by ICP for 31 elements including high field strength elements
  - d. ME-MS42 – aqua regia dissolution followed by 10 elements
  - e. ME-4ACD81 – four acid dissolution followed by ICP for ten elements

## **Lithogeochemistry Results**

The lithogeochemistry analyses confirm the historically reported values of cesium, lithium and tantalum. The details are provided in the appendices 1 and 2.

## **Mini-Bulk Sample**

An additional mini-bulk sample of ~500kg was collected in 2021 from the Pollucite Dyke. A total of 25 pails of hand-sized rock were collected from a historic trench (see Figure 6 in Fall 2020 Program section) on the main outcrop of the dyke, located at NAD 83 Zone 16 0411604E 5722772N. Twenty pails contained pegmatite rock and five pails contained mafic and felsic volcanic host rock. The pails were slung by helicopter (Whisk Air) from the Pollucite Dyke to the helicopter pad at the base camp (NAD 83 411723E 5720814N) in two loads. From there they were flown out by float plane (NDK Air) to Pickle Lake and transported by truck (Richard Brett) to Kenora where they were put in storage at the Avalon warehouse. The mini bulk sample was collected for analytical verification of cesium grades and for preliminary metallurgical test work for concentrating pollucite.

## **Soil Geochemistry**

A soil sampling program was carried out over eight days, mainly in the northern area of the claims. North-south running lines were sampled at 50m intervals, ground permitting at a depth varying between 10 to 40cm. The soil samples consisted of B horizon.

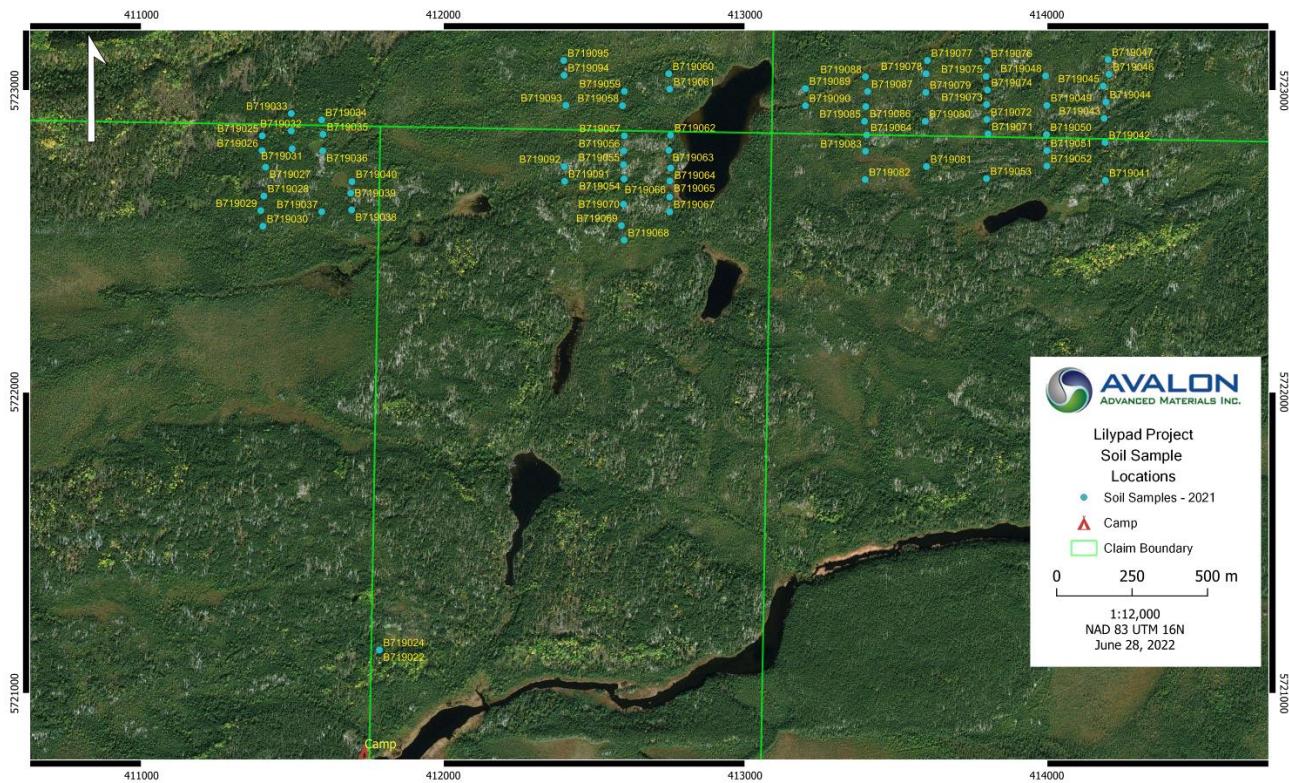

Figure 26: Soil Sample Locations

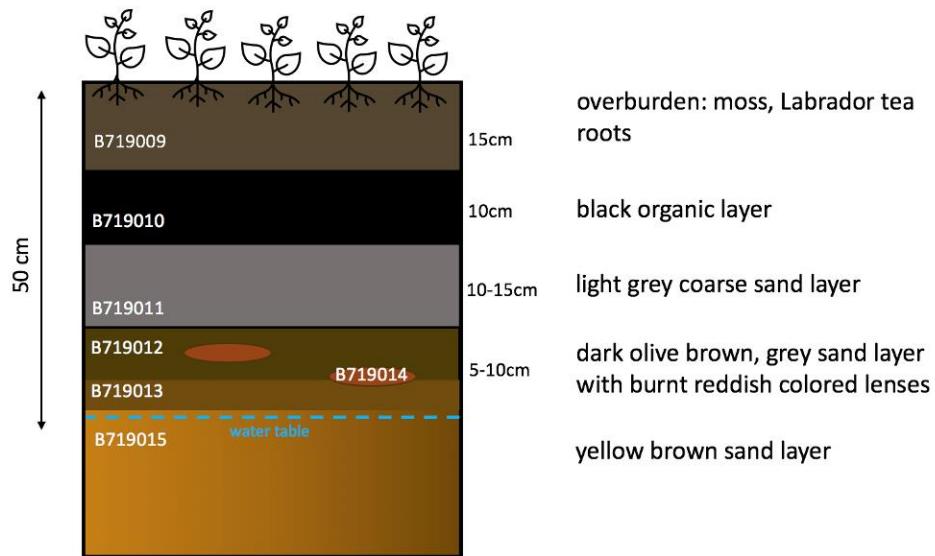

The 0.3kg weight samples were collected with the use of a soil auger and in some cases with a small shovel. The use of a soil color and grain size chart facilitated the description of the samples. The collected soil and a laboratory ID tag were enclosed in Kraft paper bags with a zip tie. The bags were labeled with the same number as the laboratory ID. The often wet or damp soil bags were laid out in camp to dry prior to transportation to the laboratory for analyses. Each sample location was flagged and the UTM coordinates were recorded with a Garmin 64 handheld GPS, as well as a description of the vegetation and ground were recorded. Samples were transported in rice bags by float plane to Armstrong Station and then by truck to the Thunder Bay ALS laboratory, Ontario. A total of 94 soil samples were submitted to the laboratory for multielement analysis. The main objective of the analysis was to test the utility of multielement analysis of soils for outlining potential extension of any known pegmatite dykes and the possibility of discovering new pegmatites covered by soil, glacial till and/or vegetation.

Soil samples, averaging 300 grams in weight (200-500 grams range) after drying at camp and shipping, were subject to preparation using ALS methods PREP-41 followed by ME-MS41L. The methods can be summarized as:

1. PREP41 – dry and sieve to 180 µ
2. ME-MS41L – aqua regia dissolution followed by ICP analysis for 43 elements

Apart from sampling lines, two soil profiles were conducted on the eastern and western margins of the Pollicite Dyke outcrop. The aim was to identify if the Cs concentrations would be increased in close proximity to the pegmatite and to potentially observe a change of the Cs level in the different soil horizons. The description of the two profiles is illustrated in the figures below. A soil profile was also collected at the Spodumene Dyke but with no detailed description.

The soil profiles do not provide clear definitive data but do suggest that samples at least 20 to 40cms down, assumed to be true B horizon, are superior for Cs, Ta and Li but Profile 1 showed stronger Cs on surface in what would be weak B horizon.

## Profile 1 Pollucite Dyke

(All elements in ppm, tantalum on right axis)

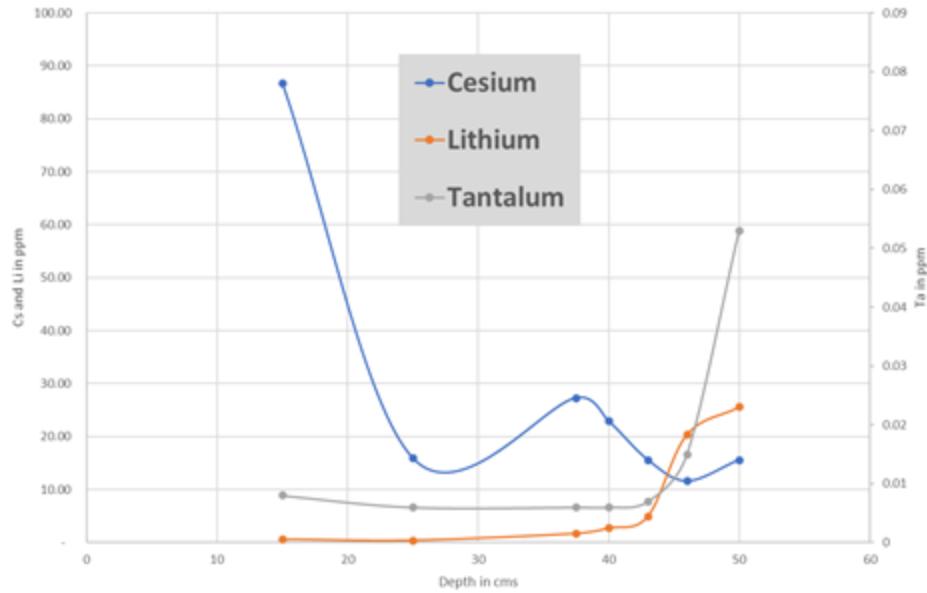

Figure 27: Schematic and elemental profile at Profile 1 on Pollucite Dyke

## Profile 2 Pollucite Dyke

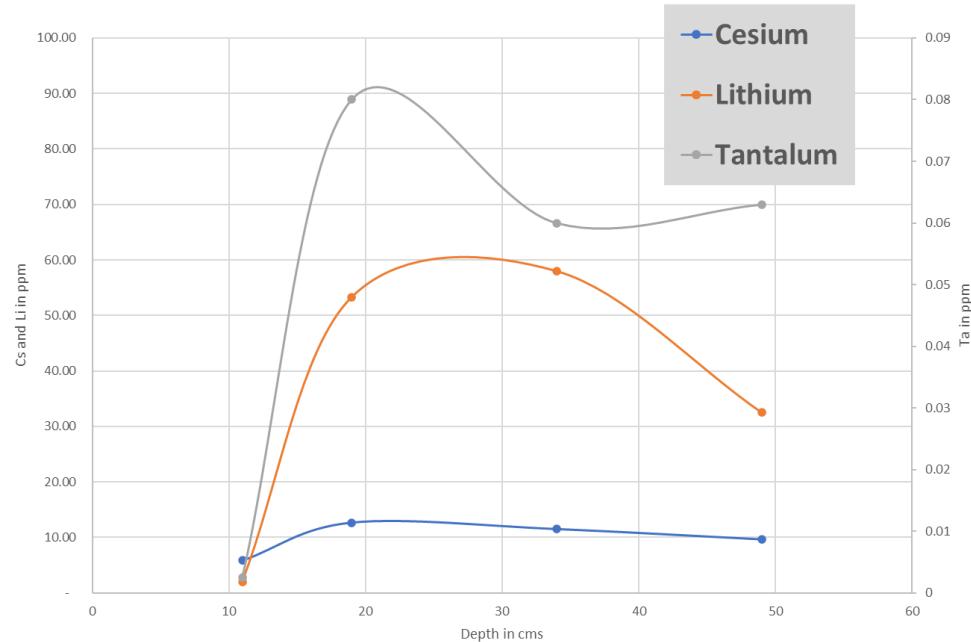

Figure 28: Schematic and elemental profile at Soil Profile 2 at Pollucite Dyke

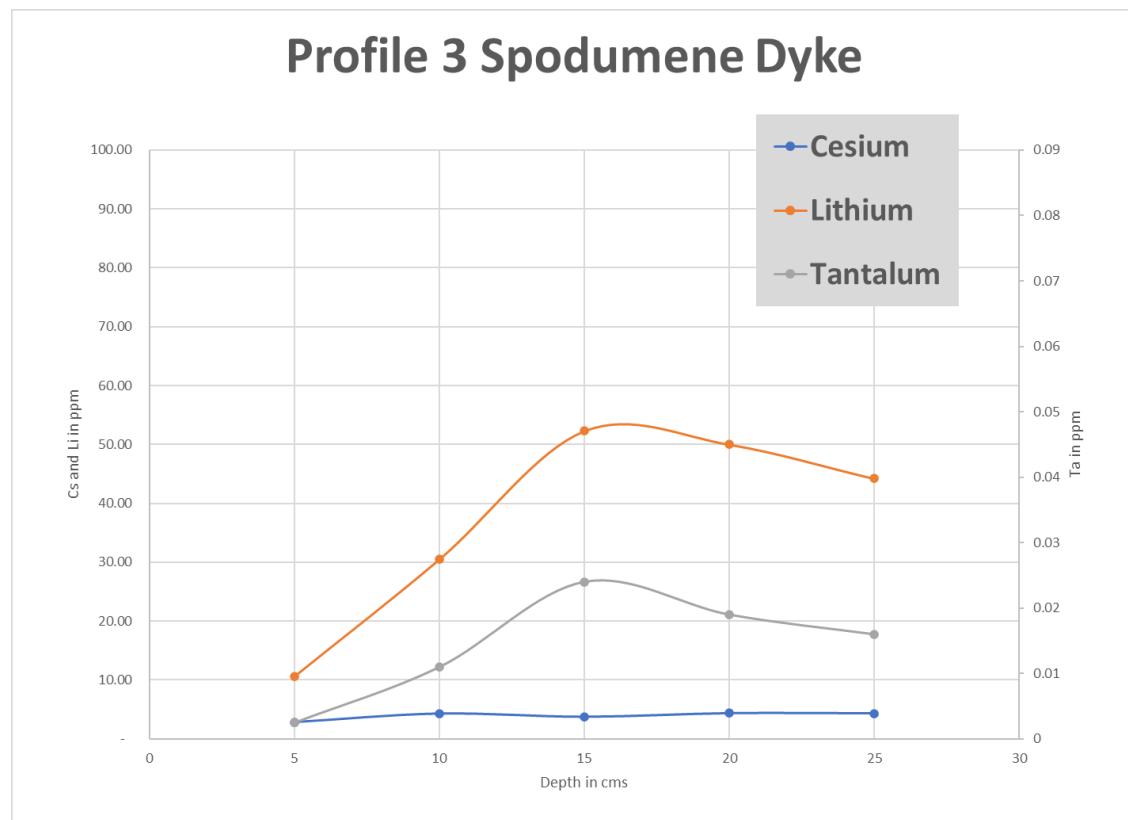

Figure 29: Elemental Profile Spodumene Dyke (no profile available)

## The Regional Soil Sampling

Soil samples were collected at Lilypad in locations where soil was clearly present and not poorly developed due to being swampy, which is a smaller area of the property than that covered by black spruce, utilized for biogeochemistry.

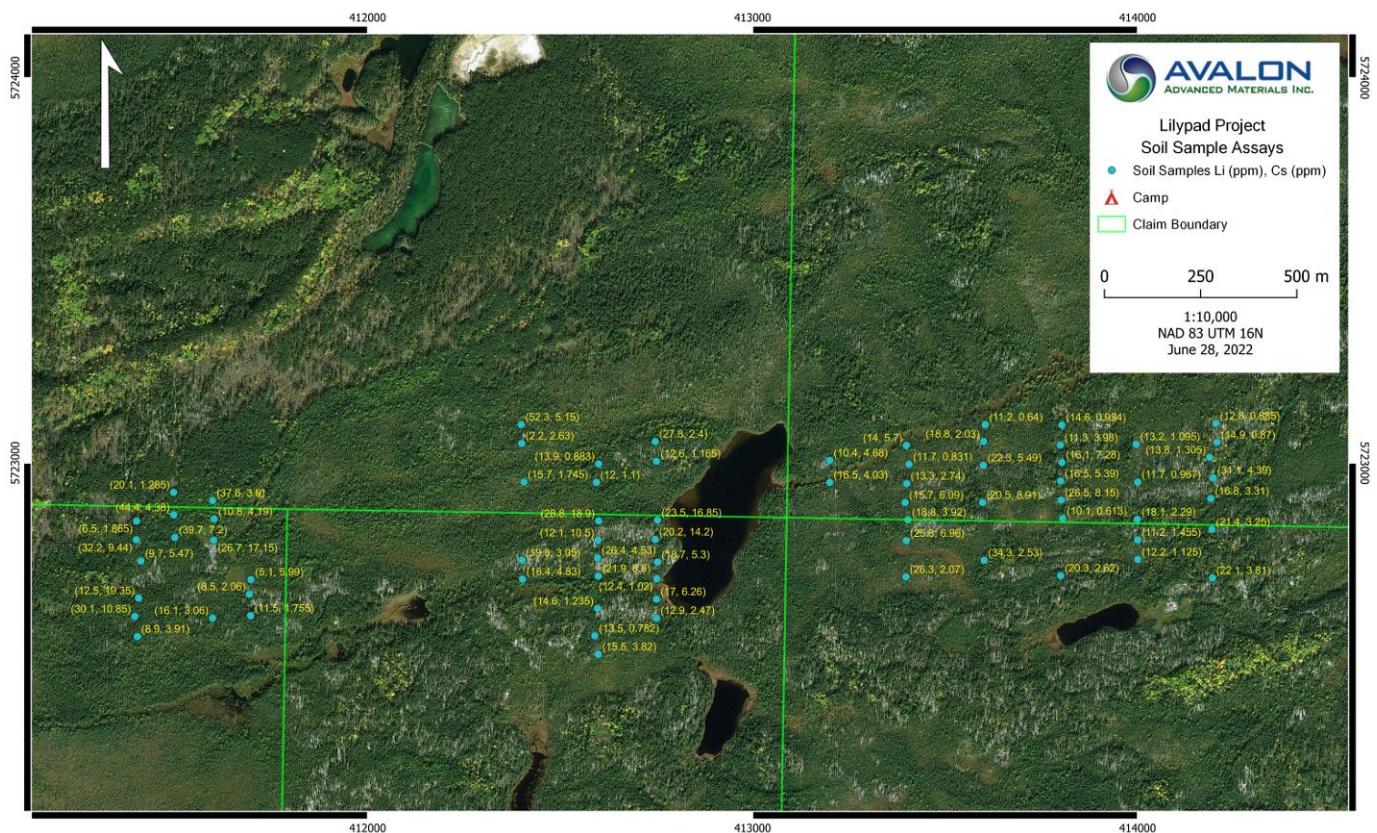

Figure 30: Li and Cs Values in Soil Samples (ppm)

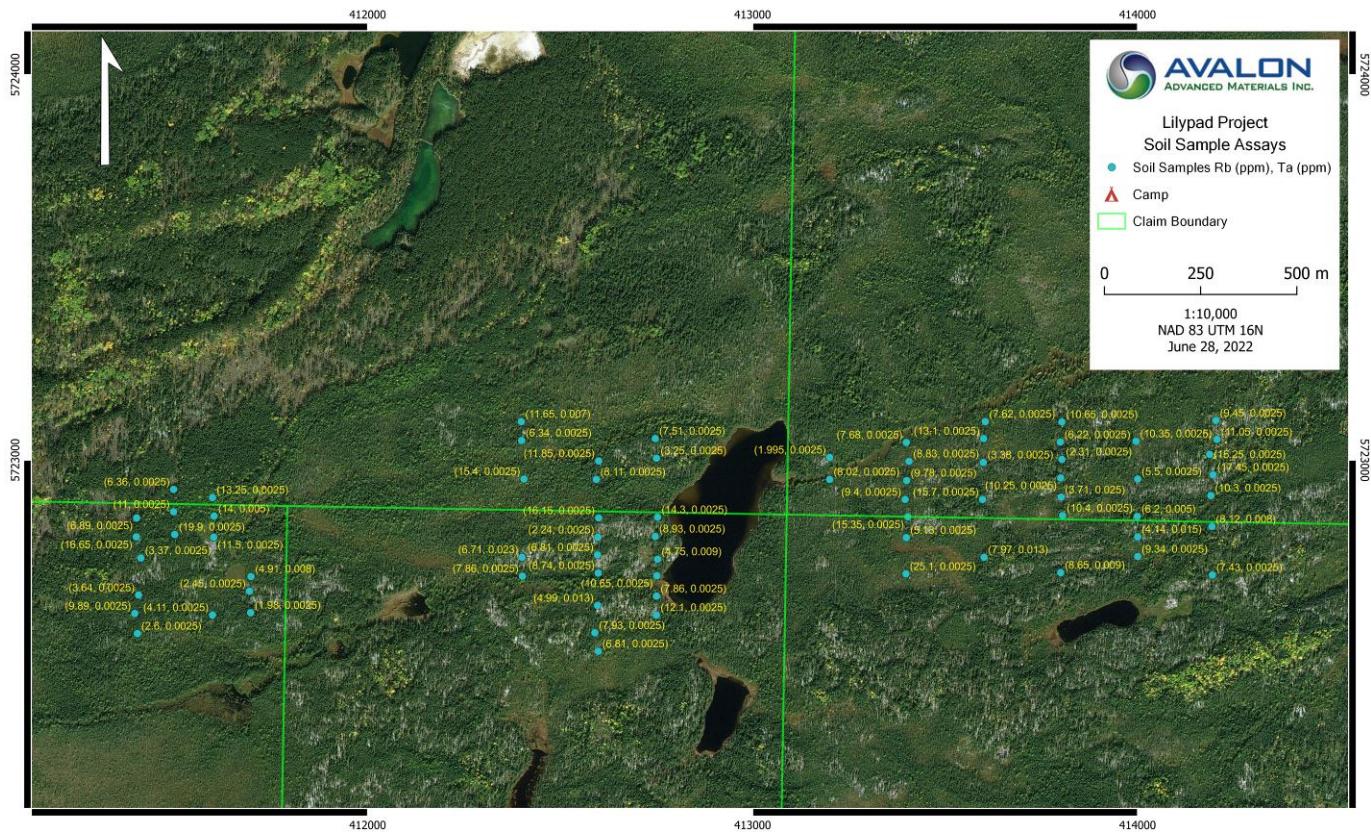

Figure 31: Rb and Ta Values in Soil Samples (ppm)

The soil results for Cs and Li show anomalies in a variety of locations without known mineralization and thus justify further field prospecting and sampling. Of the high Cs in soil only one is close to the Pollucite Dyke. Of the high Li values, some three out of ten are close to the Spodumene Dyke and the remaining seven not assigned to a known occurrence. The results have demonstrated that soil reflects underlying bedrock mineralization and have generated numerous targets for further investigation.

## Biogeochemistry

A biogeochemistry (vegetation) sampling program was carried out over the historically unsampled low percent outcrop swamp areas, as well as over the main outcrops of the Pollucite Dyke, Rubellite Dyke and Spodumene Dyke. The objective was to seek Cs, Li and Ta as tracer elements in the chemistry of the vegetation and potentially detect hidden (covered) pegmatite occurrences.

A total of 728 vegetation samples were collected during a period of 19 days. The vegetation samples consisted of approximately 0.25kg of freshly cut branches with needles of black spruce trees. Black spruce was chosen as a widely distributed abundant tree with known

good biogeochemistry responses from sampling for similar metals elsewhere. Utilizing one species removes the variability due to tree species. Samples were taken at 50m intervals on north-south sampling lines. Sampling lines going across the Pollucite Dyke, Rubellite Dyke and Spodumene Dyke were collected at approximately 10m intervals to test the chemistry adjacent to mineralization.

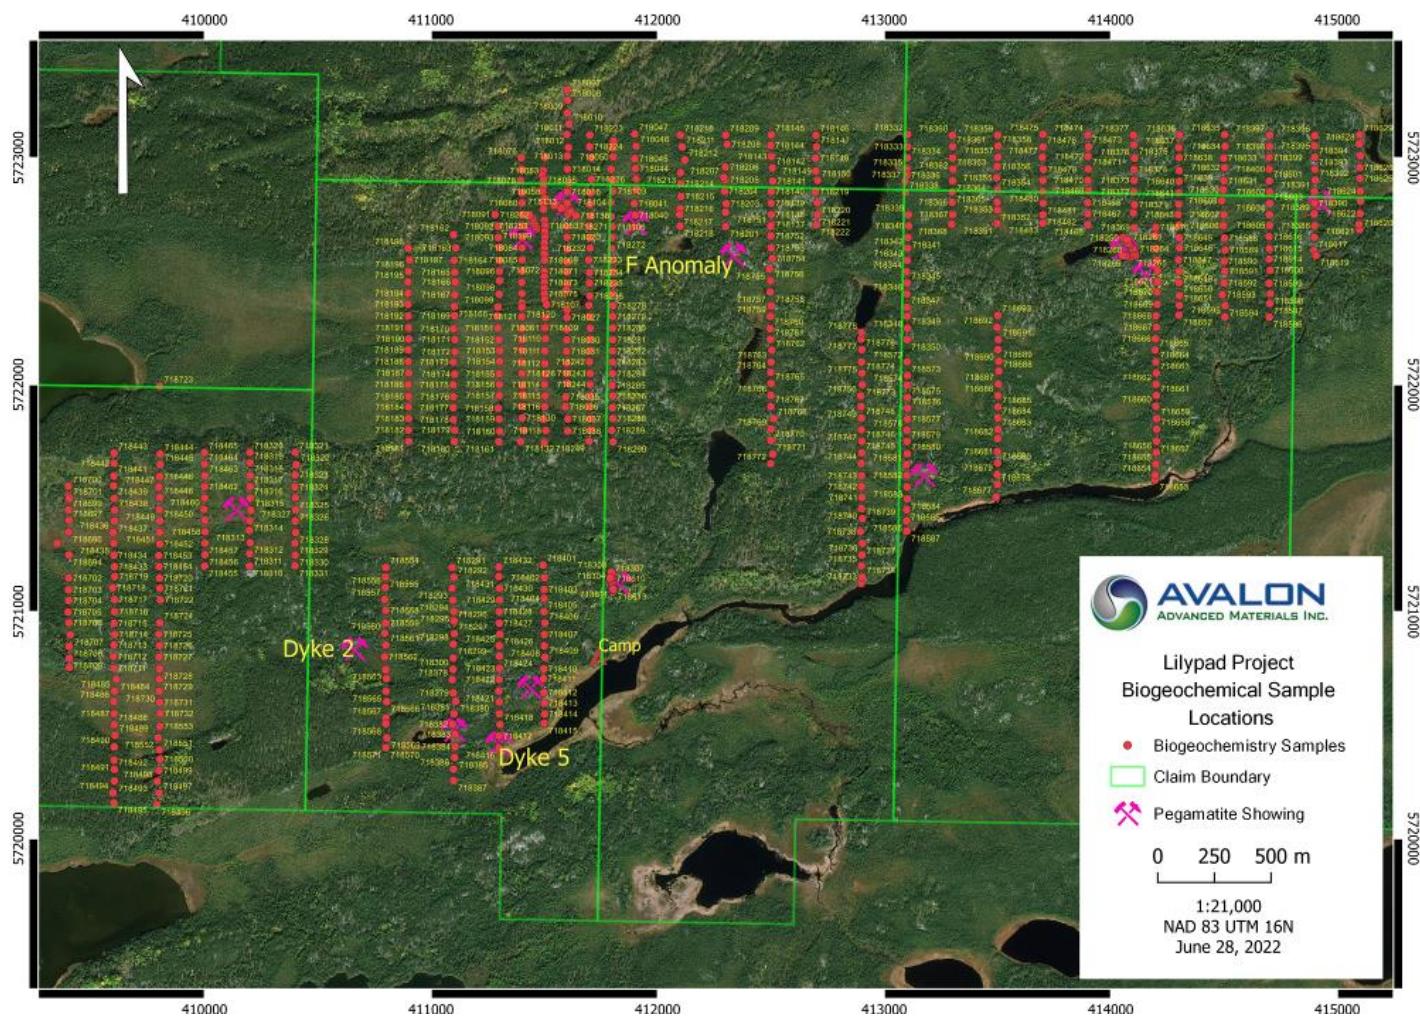

Figure 32: Biogeochemistry Sample Locations

Each sample location was flagged and the UTM coordinates were recorded on a Garmin GPS. A brief note about the ground and vegetation was made for each spot. A laboratory ID tag was included with the vegetation in the sample bag and the latter was numbered with the corresponding lab ID on both sides. Where possible, the same size of tree was being sampled. Branches were cut off with a clipper. Sample bags were left out in the sun to dry before being closed up with zip ties for transportation. Samples were transported in rice bags by float plane to Armstrong Station and then by truck to the ALS Laboratory in Thunder Bay, Ontario.

Vegetation samples for biogeochemistry were sent to ALS Laboratory for VEG-Mil01 followed by ME-VEG41 or alternatively ashing and method ME-VEG41a. The methods can be summarized as follows:

1. ME-MILL01 – the vegetation sample is milled to 100% passing 1mm, after drying
2. VEG-ASH01 – the sample after drying is ashed at 475°C for 24 hours. The weights before and after are recorded. Typical yields are 2 to 4% of the original material. The concentration factor is about 40X.
3. ME-VEG41 or ME-VEG41a comprises Aqua regia acid digestion and ICP-MS measurement, 53 elements, using 1g of finely milled material or for VEG41a, 0.25g of ashed material

The vegetation samples averaged 250g in weight, which was reduced to about 20g after drying and after ashing, to about 0.5g. As 0.25g was required for analysis of ashed samples, there was an adequate amount of sample after ashing.

Figure 33: Biogeochemistry Sampling in Field

Figure 34: Flagged sample locations near Spodumene Dyke 411809E 5721127N NAD83

## Biogeochemistry Results

In conclusion, for the analyses of vegetation samples, it can clearly be seen that the anomalous values are defining areas of known mineralization really well. Of the 42 samples, out of 273, that have anomalous values of one or more of Cs, Li and Ta, sixteen are in the Rubellite Dyke area, thirteen are in the Pollucite Dyke area and thirteen are not presently assigned to one of the known pegmatites. An advantage of biogeochemistry, as opposed to soil surveys, at Lilypad is that much of the property has poorly developed soil profiles, often due to the ground's swampy nature, but trees are present throughout the property.

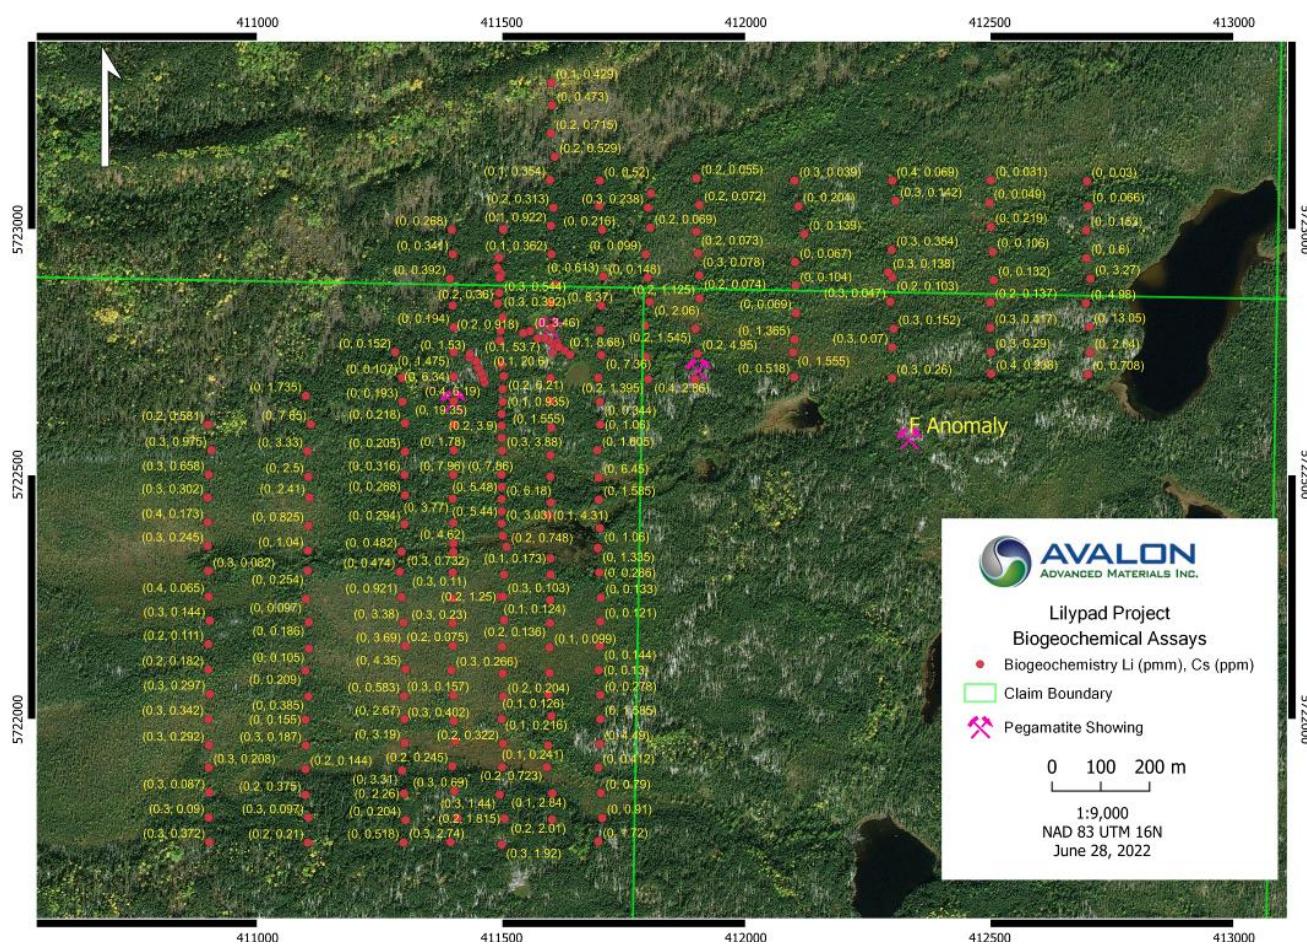

Figure 35: Biogeochemistry Values Li and Cs (ppm)

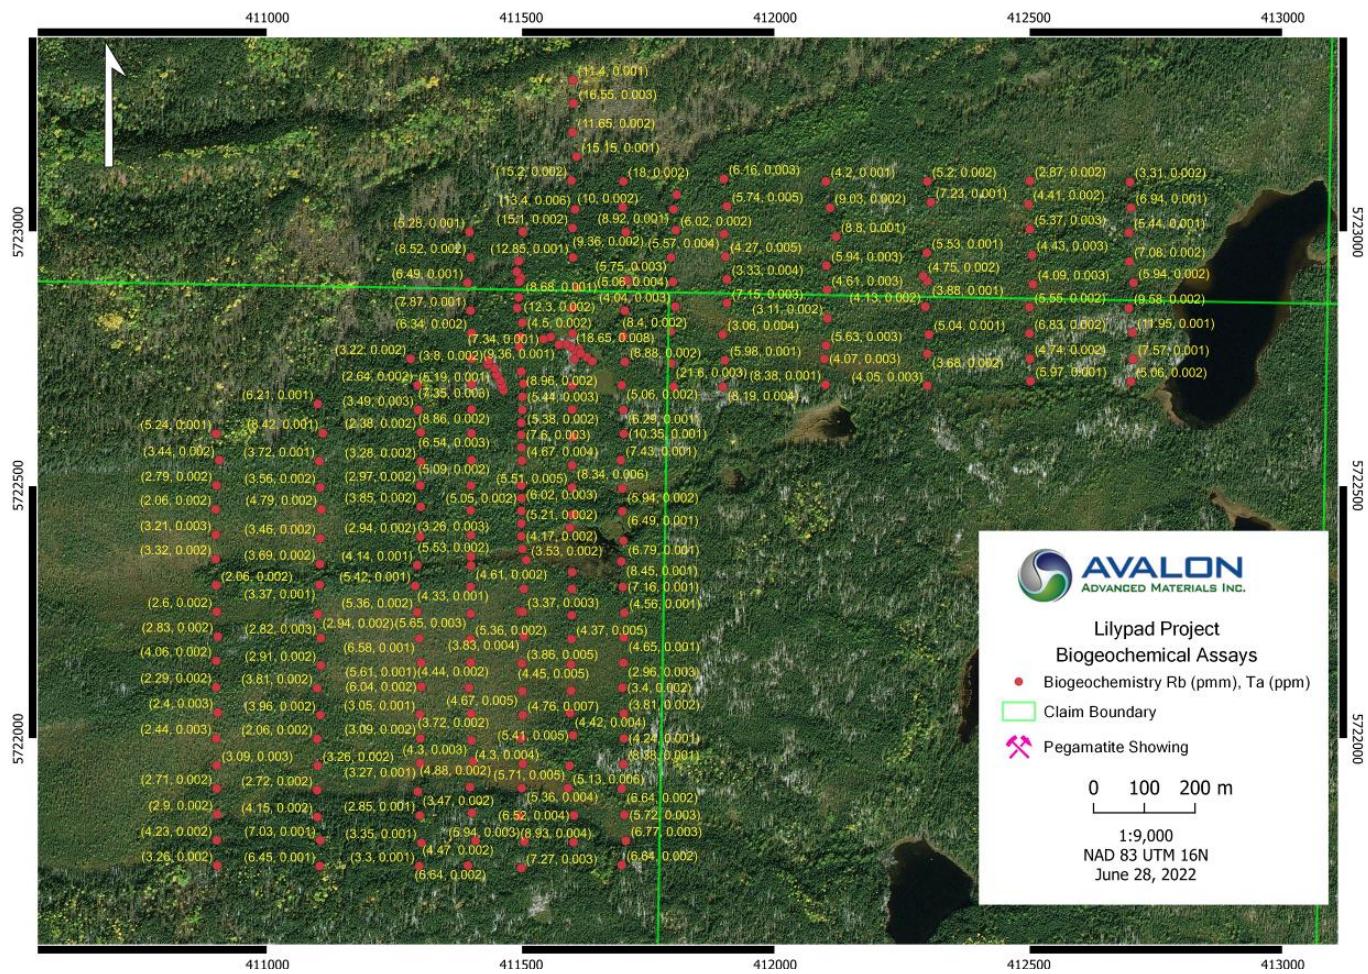

Figure 36: Biogeochemistry Values Rb and Ta (ppm)

With the Cs value in tree twigs ranked from twenty highest to lowest, eight are within the area of the Pollucite Dyke (including the six highest values), nine are near the Rubellite Dyke and two in areas not designated as close to a known dyke. Of the ten highest Li values, three are near the Pollucite Dyke, one near the Rubellite Dyke and the remaining six not presently assigned to one of the known pegmatites. For Ta there are five of the top ten values close to the Pollucite Dyke and five not assigned to an existing dyke.

In summary, the highly anomalous values close to known dykes demonstrate the validity of vegetation analyses for detecting the presence of mineralisation. The fifteen values not close to the Pollucite or Rubellite Dykes with one or more of the mineralization key elements at anomalous levels – Cs, Li, Rb or Ta – are useful targets for further investigation. Meanwhile a further approximately 500 vegetation samples are in process of being analysed.

# Water Geochemistry

## Description of Field and Laboratory Methods

A surface water sampling program was carried out on seven days at ten locations. Thirteen surface water samples were collected at various streams, creeks and lakes on the Lilypad claims, with two background control samples approximately 20km away from Lilypad camp and off the claims. Four additional samples were collected but were lost in transit to the laboratory and are ignored in this report.

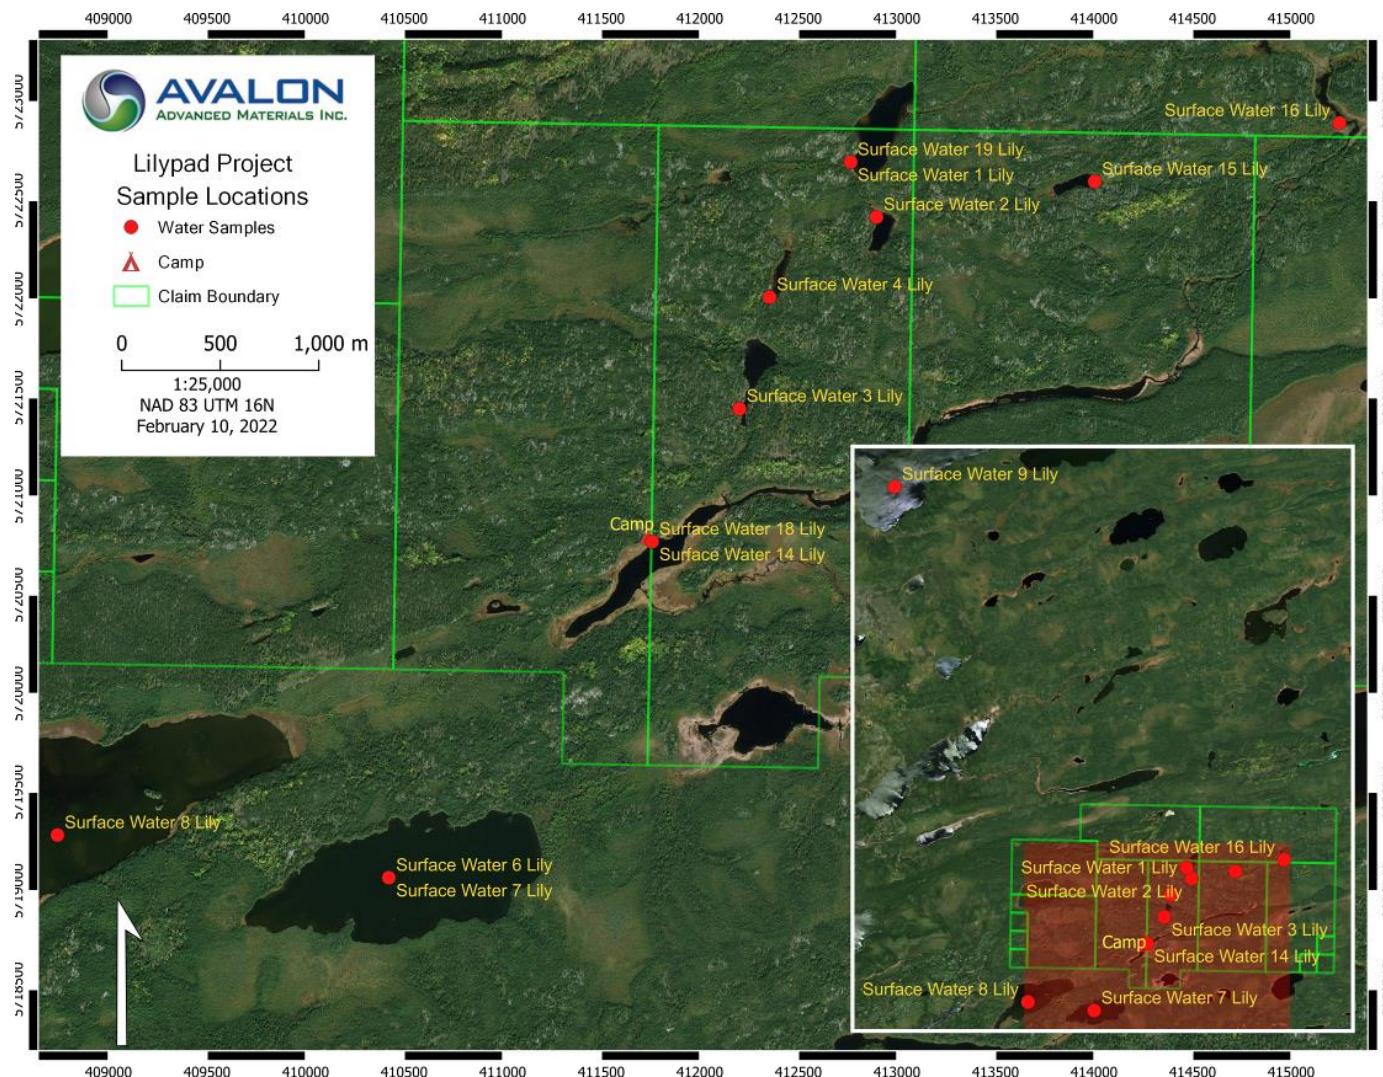

Figure 37: Baseline Water Sample Locations

ALS provided Avalon with a sampling protocol. Sampling was done with the help of a pitcher to collect the water to fill it carefully in the specific water sampling bottles provided by the ALS Environmental Laboratory. The pitcher was rinsed several times at each sampling location before the actual water sample was taken. The sampler did not touch the rims of the sampling bottles nor the spout of the pitcher with their fingers. The sampling protocol provided by ALS stated to not use the sampling bottles directly as some of them contained a liquid inside the bottle which could have escaped during the filling. They also emphasized to not overfill the bottles as the pre-existing liquid with chemicals would also have been lost in that case. Since access at the shores was often difficult, one big sample was collected with a pitcher and the sample bottles were subsequently filled.

At each sampling location the time of collection and the UTM coordinates as well as the temperature and pH of the water was recorded. The sampling bottles were labelled with the name of the sample collector, time of collection, a sample ID as well as the UTM coordinates. The samples were kept in a cooler with icepacks or in a refrigerator until their delivery to the ALS laboratory in Thunder Bay, Ontario. The coolers with the samples were transported by float plane from the camp to Armstrong Station and then by truck to Thunder Bay. Three duplicates and two “blanks” (bottled commercial “Spring Water” and domestic well water from Armstrong Station) were included in the analyses for quality control.

A total of fifteen samples, including the three duplicates and two blanks, were submitted to the laboratory for analyses to develop a baseline of the chemistry of the surface waters on the claims in order to be used as a reference for future work at Lilypad Property.

## **Interpretation of Results**

Water quality analysis sampling was successfully undertaken at eleven sites, with multiple parameters being analyzed. The details of the samples and analyses are included in the appendices to this report. At three sites a duplicate was also collected. The objective was to obtain preliminary baseline water data at the scale of an exploration project, prior to any significant surface disturbance that would be useful for future permitting and community consultation considerations.

The main points from the analyses are:

- There were no exceedances of MDMER regulatory limits
- pH levels were all within CCME guidelines, and only two locations had pH marginally higher than 8.0 (8.06 and 8.08)
- Total silver levels were above CCME guidelines at sites 19 (near mineralization), 3, 4, 6 & 7, with site 3 being significantly higher than any other site (near anomaly east).

- However, it is also worth noting that the high silver values in samples 14 and 19 were not repeated in the duplicates at those two sites (samples 18 and 1 respectively).
- Also two of the three highest silver values were in the “blanks” – Armstrong well water and commercial drinking water purchased from a grocery store.
- Total Cyanide, Total Cobalt, Total Lead, dissolved Cadmium, and Mercury (total and dissolved) all fell below detection limits at all sampling locations.
- All instances of total and dissolved Copper, Nickel, Molybdenum, and Zinc were well below CCME guidelines, with many falling below detection limits
- While all instances of Iron fell under CCME guidelines, Lily 1 (located near mineralization) shows an Iron concentration of 0.259 mg/L, near to the 0.3 mg/L allowable limit. This is a surprising result, considering that the relatively high pH of the sample.
- Total Cesium shows higher values close to mineralization of the order of 0.000X mg/l and in lakes distant from mineralization of the order of 0.0000X mg/l. Dissolved Cesium shows the same orders of magnitude. Lithium does not show such clear trends.
- There are not any water quality parameters of concern in this study that should preclude any further exploration work being undertaken at site.

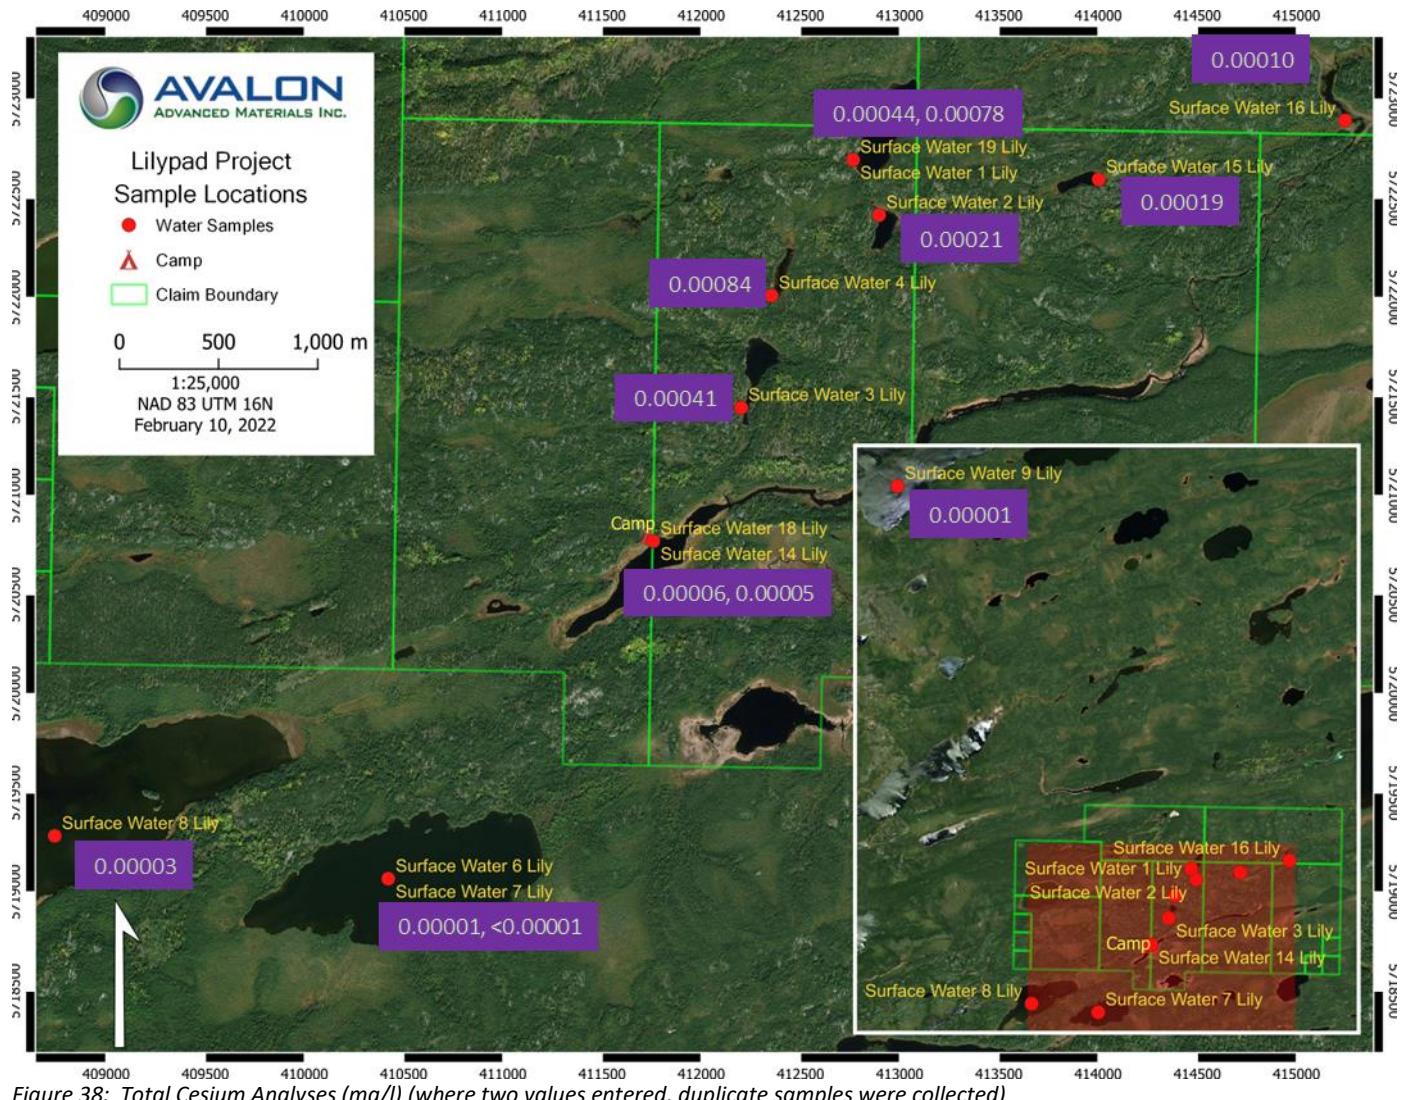

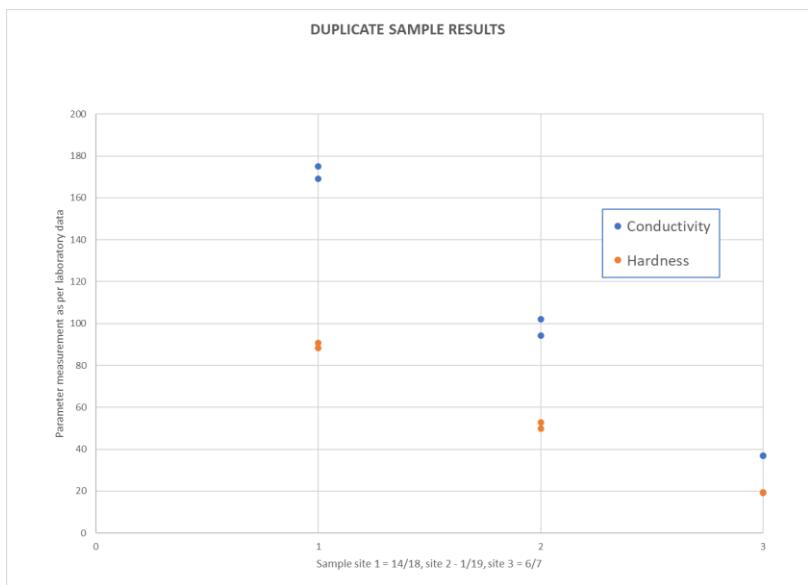

Figure 38: Total Cesium Analyses (mg/l) (where two values entered, duplicate samples were collected)

The duplicate samples show good comparison helping validate the results. For example, graphs show reasonable agreement between the three duplicate sets for selected parameters. Only Cesium shows wide variation with site 2 showing high Cs and Li in samples Lily-1 and about half the level in Lily-19. It should be noted that these two samples were in different analytical batches.

## **CONCLUSIONS AND RECOMMENDATIONS**

The 2020 and 2021 field programs provided small bulk samples of the Pollucite Dyke suitable for bench scale metallurgical testing, an important component for advancing the project to PEA stage.

In addition, other achievements were:

- Completion of wide based soil and vegetation analyses, demonstrating that the methods work on the property for detecting mineralization.
- In addition, the surveys generated a number of targets with anomalous values of Cs, Li and Ta that merit further investigation in the field.
- Regional baseline water sampling, including a lake some distance from the property, will assist in future environmental permitting processes.
- Handheld GPS surveying of historic drill collars has confirmed the validity of the existing location database of historic drill holes.
- The 2021 field program was important also as a considerable amount of waste materials from historic field programs was removed for appropriate disposal.
- The field program was aided greatly by the employment of local indigenous people in much of the work.

The work leads to the following field work recommendations that should not require onerous permitting processes:

1. Further examination of the soil and biogeochemistry results is required to identify any targets that have the potential to be new mineralized zones for Cs, Li and/or Ta or extensions of existing zones.
2. The geochemistry methods have shown excellent mineralization tracking and the whole property should be systematically covered particularly with biogeochemistry.
3. Further lithogeochemistry should accompany any exploration geochemistry. In particular some dykes that have been historically less explored have given results that suggest detailed exploration, outcrop stripping trenching and sampling.
4. A fundamental requirement is a new updated digital detailed geological map of the property. This should be accompanied by careful digitization and georeferencing the carefully made geological maps in Rees, 2001.
5. Consideration should be given to covering the property with high resolution close spaced airborne magnetic survey for outlining the potential areas of dykes given the likely magnetic contrast between the dykes (very low to zero magnetism) to the country rocks.

6. It is obvious that detection of hidden dykes or dyke extensions would be assisted by further biogeochemistry accompanied by detailed airborne magnetics and any possible outcrop stripping,
7. The existing historic drill core on site should be completely reboxed, labelled and racked and not left in the present state of disorganization. This requires careful work supervised by a qualified geologist.

Any field work should be accompanied by laboratory studies such as petrography, Qemscan and other methods to detail the mineralogical nature of the pegmatites for input to any processing methods tested at the bench scale. An important outcome of such work would be the identification of ore types for geometallurgical considerations.

Any planned drilling, as well as targeting increasing the tonnage of the known deposits, should also include:

1. Investigation the nature of zoning in the deposits. The naming of the deposits as Rubellite and Pollucite Dykes suggests that one has potential for Cs mineralization and the other for Ta-Rb. But a more careful examination of the geological details of the deposits indicates that the dykes all have Cs and Li potential and exhibit strong elemental zoning that is not well identified at present due to the paucity of drilling. There is danger that the potential of a dyke for any particular economic mineralization is obscured by the chance of the level of erosion.
2. Testing any new anomalous areas identified by soil- and biogeochemistry.
3. Consideration should be given to surface stripping either prior to or accompanying any drill program.

## APPENDIX 1: LITHOGEOCHEMICAL SAMPLE LOCATIONS

### Lithology Samples Lilypad 2021

E	N	Sample #	Date Sampled	Lithology	Showing	Sampled by	Description	Notes	Thin Section ID
411385	5722644	B718501	29/07/2021	Pegmatite	Pollucite Dyke West extension	Sarah Bodeving	Possible pegmatite extension underneath esker. Rubellite and lepidolite present. In contact with host rock. Angular, not rounded so believed to not have moved much. But not in situ.	Half ALS, half McGill.. Quemscan	
411843	5721155	B718502	31/07/2021	Pegmatite	Spodumene Dyke	Sarah Bodeving	Swamp outcrop. Glassy grey qtz and pinkish white Ksp. 10cm spd crystal. Lots of green mica.	Half ALS, half McGill.	
411809	5721127	B718503	31/07/2021	Pegmatite	Spodumene Dyke	Sarah Bodeving	Main spodumene dyke outcrop. Very saccharoidal. White an green mica. No other minerals distinguishable.	Lots of smaller pieces to lab and one larger piece to McGill.	
411810	5721119	B718504	31/07/2021	Pegmatite	Spodumene Dyke	Sarah Bodeving	Dyke with seagreen spd.	Too big to break in half. All to McGill.	
411816	5721118	B718505	31/07/2021	Pegmatite	Spodumene Dyke	Sarah Bodeving	Edge of swirlly pegmatite. Very saccharoidal. No spd visible.	Half ALS, half McGill.	
411839	5721127	B718506	31/07/2021	Pegmatite	Spodumene Dyke	Richard Brett/ Sarah Bodeving	Along snake outcrop. Green mica, pink albite? kfsp, maybe spd?	Too big to break in half. All to McGill.	
411863	5721112	B718507	31/07/2021	Pegmatite	Spodumene Dyke	Richard Brett	Along snake outcrop. Completely white saccharoidal with smaller orange pieces, no spd visible.	Half ALS, half McGill.	
411858	5721121	B718508	31/07/2021	Pegmatite	Spodumene Dyke	Richard Brett	Along snake outcrop. Beautiful sample with green spd, quartz, Kfsp.	Broke smaller pieces off for lab, big chunk to McGill.	
411793	5721153	B718509	31/07/2021	Pegmatite	Spodumene Dyke	Sarah Bodeving	Main blast outcrop. Very coarse spd xts, seem to be coated with darker mica.	Half ALS, half McGill. Quemscan	
411438	5720668	B718510	01/08/2021	Pegmatite	West of Camp	Richard Brett	Pegmatitic dyke at anomaly point. Lots of green mica, cubic dark mineral, white albite and quartz.	Half ALS, half McGill.	
411342	5720423	B718511	01/08/2021	Pegmatite	West of Camp	Richard Brett	Weird vein at anomaly, very coarse qtz in center and then finegrained laminated white greenish mica around.	All to ALS. Too brittle.	
411312	5720421	B718512	01/08/2021	Pegmatite	West of Camp	Richard Brett	Albitic dyke with green mica, blue apatite, cross cut by reddish veinlet	Half ALS, half McGill.	
411236	5720420	B718513	01/08/2021	Pegmatite	West of Camp	Richard Brett	Albitic dyke with green mica. Similar to the one before	Half ALS, half McGill.	
411406	5722666	B718514	02/08/2021	Pegmatite	Pollucite Dyke West extension	Sarah Bodeving	Last outcrop before esker. Rubellite, lepidolite present.	Half ALS, half McGill. Quemscan.	PD21_1 PD21_1.1
411698	5722758	B718515	02/08/2021	Pegmatite	Pollucite Dyke East extension	Sarah Bodeving	Composite grab. Smaller pieces of albitite dykes. No lpd visible.	All to ALS.	
411902	5722715	B718516	02/08/2021	Pegmatite	Pollucite Dyke East extension	Sarah Bodeving	Bigger dyke. Purple fluorite? Maybe lepidolite present.	Half ALS, half McGill.	
?	?	B718517	03/08/2021	Pegmatite	West of Camp	Richard Brett	30cm wide? large boulder? pegmatite, green mica, albite	Half ALS, half McGill.	
410662	5720837	B718518	03/08/2021	Pegmatite	West of Camp	Richard Brett	1 to 5cm wide dyke, white coarse grained	All to ALS.	
411101	5720481	B718519	03/08/2021	Pegmatite	West of Camp	Richard Brett	Pegmatite	All to ALS.	
412334	5722574	B718520	03/08/2021	Pegmatite	F anomaly	Sarah Bodeving	Grab sample, white albitic with some purple, maybe rub, lots of qtz.	Half ALS, half McGill.	FA21_2

E	N	Sample #	Date Sampled	Lithology	Showing	Sampled by	Description	Notes	Thin Section ID
412282	5722471	B718521	03/08/2021	Pegmatite	F anomaly	Sarah Bodeving	Grab along channel, chips.	All to ALS.	
414155	5722491	B718522	06/08/2021	Pegmatite	Baseline Dyke	Sarah Bodeving	Some lpd, maybe some rubellite?	Half ALS, half McGill.	BD21_3
414161	5722539	B718523	06/08/2021	Pegmatite	Baseline Dyke	Sarah Bodeving	Close to baseline dyke, more lpd	Half ALS, half McGill.	BD21_4
414927	5722804	B718524	06/08/2021	Pegmatite	Opie Dyke	Sarah Bodeving	2 pieces with lepidolite, rest coarse grained white Kfsp? or Spd?	Half ALS, half McGill. Quemscan	OD21_5
415106	5722773	B718525	06/08/2021	Pegmatite	Along swamp	Richard Brett	Squiggly quartz rich, green mica? part on edge of swamp. Richard picked up close to Opie dyke	All to ALS.	
414080	5722581	B718526	06/08/2021	Pegmatite	Rubellite Dyke	Sarah Bodeving	Finergrained rub and spd, and lpd, coarse spd	Half ALS, half McGill.	RD21_6
414080	5722581	B718527	06/08/2021	Pegmatite	Rubellite Dyke	Sarah Bodeving	Section with coarse purple lpd, other section with coarse rub and spd, coarse qtz	Half ALS, half McGill. Quemscan	
414080	5722581	B718528	06/08/2021	Pegmatite	Rubellite Dyke	Sarah Bodeving	lpd rich, maybe pollucite in stringers?	Half ALS, half McGill.	RD21_7

### Lithochem ALS

- Not sent to ALS as too big to saw in half at McGill
- Retained for petrographic work

## APPENDIX 2: LITHOGEOCHEMICAL ANALYSES

**Report Version 1TB21218459 - Finalized**

**CLIENT : OPG - Avalon Advanced Materials Inc.**

## APPENDIX 3: SOIL SAMPLE LOCATIONS

### Soil Sampling Log

E	N	Sample #	Soil	Vegetation	Date sampled	Line	Depth	Notes	Sampled by
411705	5722748	B719002	Silt, clay	Spruce stand	29th June 2021	411700	21cm		Kelvin W/Tyrese
411700	5722801	B719003	silt, sand	Spruce stand	29th June 2021	411700	10cm	rocky under peat	Kelvin W/Tyrese
411700	5722859	B719004	coarse silt, sand	rock outcrop	29th June 2021	411700	25-75 cm		Kelvin W/Tyrese
411700	5722934	B719005	silt, sand	spruce stand	29th June 2021	411700	10cm	coarse sand	Kelvin W/Tyrese
411703	5723012	B719006	coarse loam	spruce stand	29th June 2021	411700	36cm	coarse loam	Kelvin W/Tyrese
411699	5723045	B719007	coarse sand	spruce stand	29th June 2021	411700	37cm	coarse loam	Kelvin W/Tyrese
411705	5723126	B719008	coarse sand, silt, loam	spruce stand	29th June 2021	411700	17cm	coarse sand silt	Kelvin W/Tyrese
411576	5722763	B719009	peaty roots	labrador tea thick moss overburden	2nd July 2021	Poll Dyke Hole 2	5cm down from vegetation	peaty, roots top layer	Kelvin
411576	5722763	B719010	black clay, peat	labrador tea thick moss overburden	2nd July 2021	Poll Dyke Hole 2	5cm down	black organic layer	Kelvin
411576	5722763	B719011	medium sand	labrador tea thick moss overburden	2nd July 2021	Poll Dyke Hole 2	4cm down	lighter grey, equigranular, medium-fine sand	Kelvin
411576	5722763	B719012	medium sand	labrador tea thick moss overburden	2nd July 2021	Poll Dyke Hole 2	4cm down	olive coloured equigranular medium-fine sand, no gravel	Kelvin
411576	5722763	B719013	medium sand	labrador tea thick moss overburden	2nd July 2021	Poll Dyke Hole 2	3cm down	brownish coloured sand 10-15cm thick	Kelvin
411576	5722763	B719014	black sandy, clay, peat layer	labrador tea thick moss overburden	2nd July 2021	Poll Dyke Hole 2	lenses in sand layer	burnt black/brown layer as lenses in sand layer, just above water table	Kelvin
411576	5722763	B719015	medium sand	labrador tea thick moss overburden	2nd July 2021	Poll Dyke Hole 2	yellow brown sand in water		Kelvin
411621	5722773	B719016	coarse sand	labrador tea thick moss overburden	2nd July 2021	Poll Dyke Hole 1	grey coarser sand layer at top, no organic layer		Kelvin
411621	5722773	B719017	"organic layer"	labrador tea thick moss overburden	2nd July 2021	Poll Dyke Hole 1	5cm down		Kelvin
411621	5722773	B719018	coarse sand, small gravel	labrador tea thick moss overburden	2nd July 2021	Poll Dyke Hole 1		lighter brown	Kelvin
411621	5722773	B719019	coarse sand, small gravel	labrador tea thick moss overburden	2nd July 2021	Poll Dyke Hole 1		reddish brown	Kelvin
411788	5721144	B719020	rusty brown medium sand with gravel 22mm to 1cm	overburden, labrador tea	30th July 2021	Spodumene Dyke	5cm		Richard Brett
411788	5721144	B719021	rusty brown medium sand with gravel 22mm to 1cm		30th July 2021	Spodumene Dyke	10cm		Richard Brett
411788	5721144	B719022	rusty brown medium sand with gravel 22mm to 1cm		30th July 2021	Spodumene Dyke	15cm		Richard Brett
411788	5721144	B719023	rusty brown medium sand with gravel 22mm to 1cm		30th July 2021	Spodumene Dyke	20cm		Richard Brett
411788	5721144	B719024	rusty brown medium sand with gravel 22mm to 1cm		30th July 2021	Spodumene Dyke	25cm		Richard Brett

## APPENDIX 4: SOIL SAMPLE ANALYSIS

Report Version : TB21182523 - Finalized / TB21210326 - Finalized

CLIENT : OPG - Avalon Advanced Materials Inc.

# of SAMPLES : 18 + 76 = 94 Total

DATE RECEIVED : 2021-07-14 / 2021-08-11 DATE FINALIZED : 2021-08-12 / 2021-09-13

PROJECT : Project 0535

CERTIFICATE COMMENTS : ME-MS41L: Gold determinations by this method are semi-quantitative due to the small sample weight used (0.5g).

PO NUMBER :

## APPENDIX 5: BIOGEOCHEMISTRY SAMPLE LOCATIONS

### Biochemistry Sample

E	N	Sample #	Tree species	Line	Date Sampled	Notes	Sampled by
411629	5722753	718001	Black Spruce	Pollucite Dyke 1	28th June 2021	Smaller tree. Off mineralization. In overburden/swamp	Sarah Bodeving
411614	5722769	718002	Black Spruce	Pollucite Dyke 1	28th June 2021	5m off from visible pegmatite outcrop, smaller tree, lots of dead branches	Sarah Bodeving
411605	5722767	718003	Black Spruce	Pollucite Dyke 1	28th June 2021	Large tree right on mineralized pegmatite dyke. Next to blasted trench.	Sarah Bodeving
411598	5722774	718004	Black Spruce	Pollucite Dyke 1	28th June 2021	On contact of pegmatite with mafic country rock.	Sarah Bodeving
411588		718005	Black Spruce	Pollucite Dyke 1	28th June 2021	On mafic country rock.	Sarah Bodeving
411558	5722793	718006	Black Spruce	Pollucite Dyke 1	28th June 2021	Off outcrop. At edge with large spruce trees.	Sarah Bodeving
411602	5723300	718007	Black Spruce	411600	28th June 2021	Tall spruce tree on esker. Lots of erratic boulders.	Sarah Bodeving
411603	5723254	718008	Black Spruce	411600	28th June 2021	Black spruce on esker	Sarah Bodeving

## APPENDIX 7: BASELINE WATER SAMPLE LOCATIONS

### Regional Water Samples Collected

Regional Baseline Sampling								
E	N	Sample #	Date sampled	Time sampled	pH	T	Sampled by	Notes
412765	5722695	Surface Water 1 Lily	02-07-2021	12:50pm	7.98		Sarah Bodeving	Large lake, shallow shore, sampled close to creek
412896	5722416	Surface Water 2 Lily	02-07-2021	1:20pm	7.38		Sarah Bodeving	Smaller lake, very shallow shore
412201	5721444	Surface Water 3 Lily	04-07-2021	7am	7.7	21.6	Sarah Bodeving	Shallow sampling spot, muddy
412354	5722010	Surface Water 4 Lily	04-07-2021	7:40am	7.91	24.6	Sarah Bodeving	Sampling on rock, clean water
		Surface Water 5 Lily	05-07-2021	on COC form	8.03	20.6	Sarah Bodeving	Blank-natural spring water "Presidents Choice" 1.5l bottle, Source Middlebro, Manitoba, dissolved mineral salts 180 PPM, Fluoride Ions 0.1PPM
410422	5719067	Surface Water 6 Lily	05-07-2021	12:40pm	8.32	23.6	Sarah Bodeving	Ishkish Lake
410422	5719067	Surface Water 7 Lily	05-07-2021	12:50pm	8.32	23.6	Sarah Bodeving	Duplicate of surface water sample 6 lily
408741	5719283	Surface Water 8 Lily	05-07-2021	1:20pm	8.22	23.6	Sarah Bodeving	Frond Lake
405360	5732351	Surface Water 9 Lily	05-07-2021	1:50pm	8.24	24.6	Sarah Bodeving	Baseline Lake, far away from mineralization, ~ 12km away from Pollucite Dyke.
411758	5720771	Surface Water 10 Lily	28-07-2021	11:20am	7.99	19.6	Sarah Bodeving	Lilypad Lake
411357	5722348	Surface Water 11 Lily	29-07-2021	2:15pm	7.5	11.6	Sarah Bodeving	Creek West of Pollucite Dyke
411700	5722404	Surface Water 12 Lily	29-07-2021	2:40pm	6.9	19.6	Sarah Bodeving	Creek East of Pollucite Dyke
411700	5722404	Surface Water 13 Lily	29-07-2021	2:50pm	6.9	19.6	Sarah Bodeving	Duplicate of surface water sample 12 lily
411758	5720771	Surface Water 14 Lily	03-08-2021	6:00pm	8.1	26.1	Sarah Bodeving	Lilypad Lake
414003	5722596	Surface Water 15 Lily	06-08-2021	9:30am	7.34		Sarah Bodeving	Rubellite Dyke Lake
415245	5722893	Surface Water 16 Lily	06-08-2021	1:30pm	7.35		Sarah Bodeving	Creek edge of sample cut lines to East
		Surface Water 17 Lily	05-08-2021	4:00pm			Sarah Bodeving	Blank-Armstrong air base well water
411758	5720771	Surface Water 18 Lily	07-08-2021	on COC form			Sarah Bodeving	Lilypad Lake
412765	5722695	Surface Water 19 Lily	07-08-2021	9:20am			Kelvin	Resampling of surface water 1 Lily. Same location.

## APPENDIX 8: BASELINE WATER SAMPLE ANALYSES

### Regional Water Sampling Results

#### Section 1 - Lilypad Surface Water 1 – 7 (Samples 10-13 lost in transit)

#### Qualifier Legend

PEHR Parameter Exceeded Recommended Holding Time On Receipt: Proceed With Analysis As Requested.

DLM Detection Limit Adjusted due to sample matrix effects (e.g., chemical interference, colour, turbidity).
