Report prepared by Keith Vatcher for Regis Resources Inc.

Fulk Loch

Sample prep.

Work performed on several areas of the deposit at the horseshoe lake area.

Trenches A to H 08/00 to 09/00

Monies concerning sample prep. Work includes:

Areas sampled to determine different sizes and averages.

Colour.

Grade.

Drving time of material.

Expansion factors.

How material reacts to heat and how much it can absorb without losing its ability to Exfoliate.

How material reacts drying slowly verses drying fast.

Moisture content.

Areas tested before sample was taken;

All areas had oversize and under taken off before tested. Very high 40 plus High 30 plus Mid 20-30 Low below 20

trench	area	colour	size range	expansion	average
a	750n-165e	light to silver	0-5	7	very high
b	655n-25e	greenish	3-5	6	high
Ľ	575n-15w	greenish to light	3-5	5	high
	stringer	dark stingers	0-5	6-7	very high
c	575n-50w	brownish	3-5	4	mid.
d	400n-45w	greenish	4-5		low
e e f	stringer 375n-175w	greenish light to silver	0-5 3-5	3 5-7	mid high
g	250n-210w	light to silver	3-5	5-7	high
h	190n-250w	light to silver	0-5	6	mid

From total amount taken only 100lbs were sampled. From that 500 grams were used for calculations.

45 Ton sample Work performed and results

Lett cotche

A pit was dug at line 615n and 45 tons were taken from that to the building were it was piled and later loaded in truck to be shipped to Buckhorn. Due to the access trail, trucks were only able to reach the building site. A 4x4 back hole was used to dig and carry the sample. After 45 tons were at the building site on the property a truck was brought in. (Buckhorn Sand And Gravel)

When the material reached the storage testing area 4-6 persons were hired to dry and screen. The material had to be screened to several sizes to find the best means for assay and separation processes.

Our main concerns were to find averages in the different size ranges and what can be recovered. Of the 45 tons taken 30 tons were dried enough to do the testing. Three types of screens were used to screen. At the start a tramo screen was used to take off the 3/8 and over size material (approx. 5tons from total 45.) leaving 40. Then Sweko Circular Vibrating screens was used to size material into #3,4,5 and -65(under size). The material was placed into 1 ton bags. Those bags were then assayed.

SIZE WEIGHT	AVER.	FRACTIONS	SEPARATION
Waste- 5tons	n/a	+3/8	N/A
Over 0-2- 1tons	3.2	+18/-3/8	Poor(crushing needed)
#3- 3tons	13.3	+20/-18	Fair (crushing needed)
#4- 8tons	23	+30/-20	Good
#5-10tons	32	+65/-30	Good
under #6- 8tons	n/a	-65	Good
left over-5tons			
total 40 tons			

Approx. 5 tons were lost to moisture in different stages. The sample was weighed on truck scales when brought to the site. One ton bags were used to get approx. weight of size ranges.

Sizes were then ran through a air separator to separate vermiculite from dirt. The air separator was made from metal with a blower at the rear and a window at the front to allow the air to draw the lighter material to the rear.

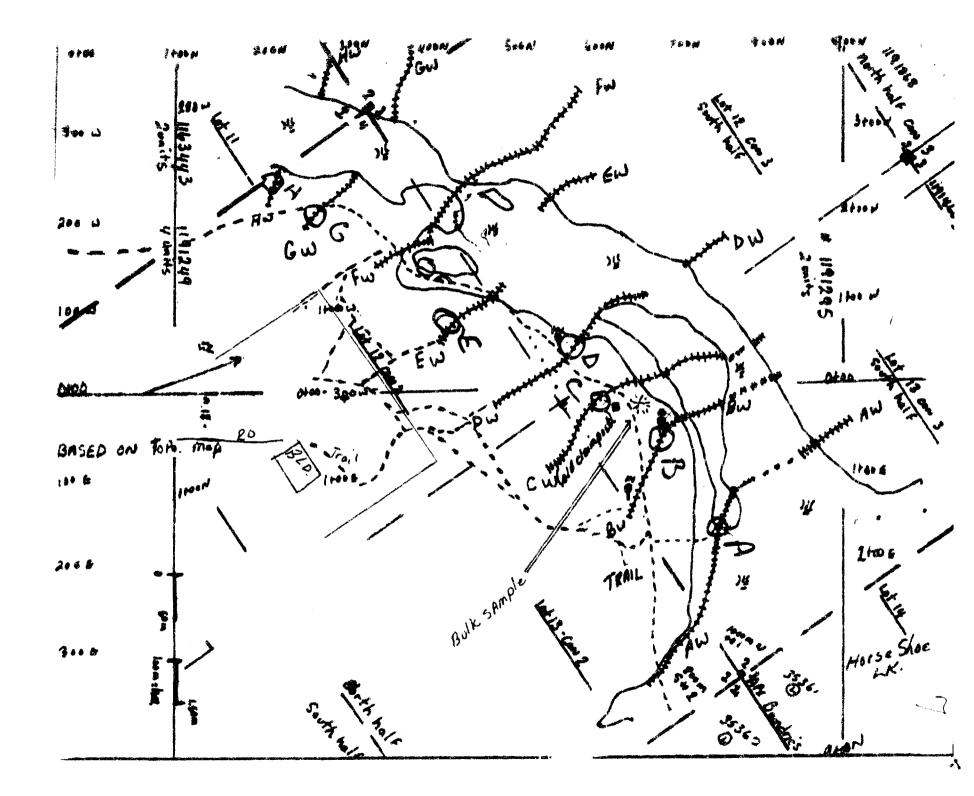

The difference in weight of vermiculite and the dirt is very little so the sizes have to be screened very close from good results. Vermiculite depending on size range can weigh as much the dirt if the proper drying isn't performed. The separator used was 30 inches wide 12 feet long 4 feet high at the front and 6 at the back. The separator had three compartments at the bottom to catch different grades of material. The front tray would contain 2.8-10% verm. 2nd 40-60% and rear tray 90-100%. Those numbers were pleasing for assay results, but the weight in the compartments needed more adjusting. The rear tray being the final product needed more material volume and less in the first tray.

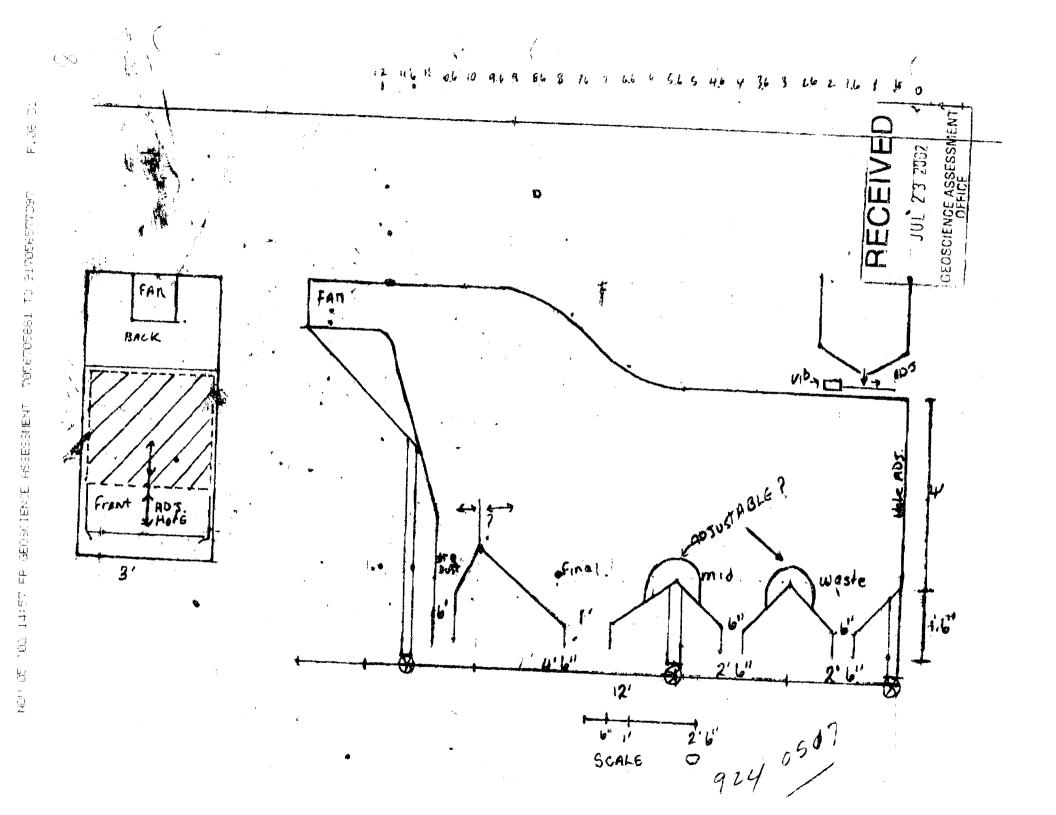

In the mid tray, when the material was rescreened the averages rose to 80^+ . Then the undersize from that material was reentered into the separator ran at higher air pressure to draw the material futher to the rear tray leaving less in the front. The waste in the first tray was replaced into bags and left. All 90% + was put into 5 gallon pals and stored.

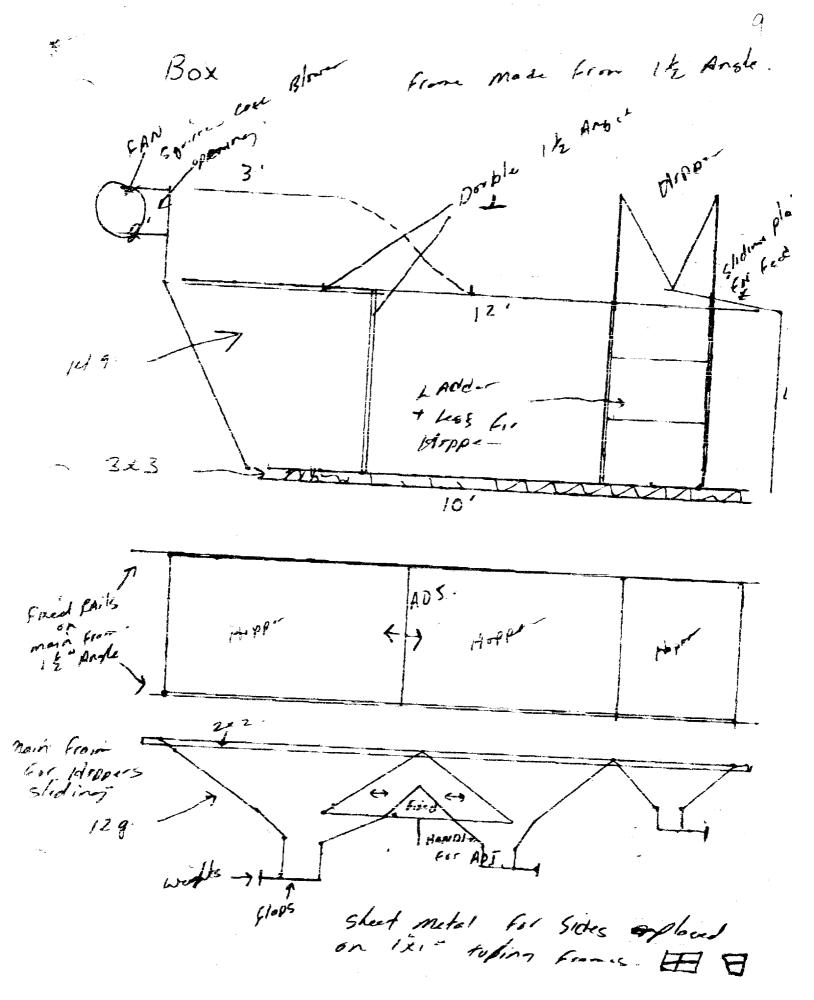

Some experimenting was done with a impact crusher to try and brake the small pebbles of rock that are more brittle then the vermiculite. This process would work with the averages if the volume could be increased and put in a closed circuit with the mids, to screens and returned to the separator. When crushing we have to be aware that vermiculite in rock do not expand as well and could effect the bulk size. We fount that if we ran # 3 we have to crush for #3 and discard the undersize.

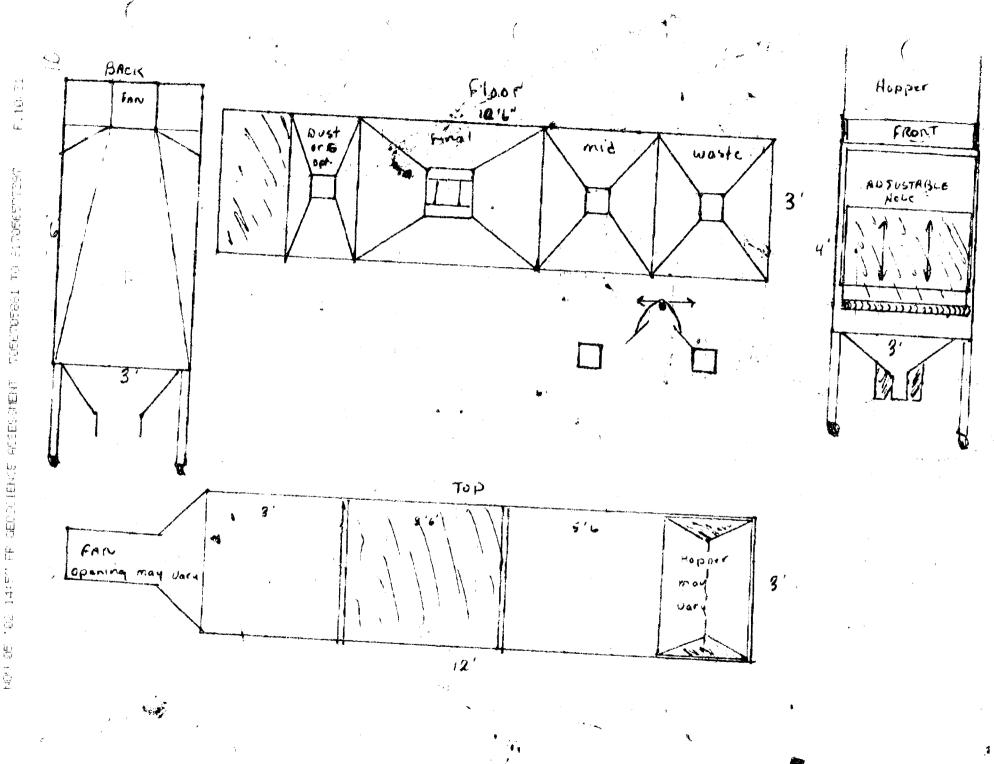

The results in the #4 and#5 were pleasing. The numbers were to 96+% where we would like to see them in the first pass. When the mids were screened assays were up to 90% leaving only small amounts of waste in the second run after rescreening.

After ran through the separator we found the best results were achieved with rectangle screens (20 in. X 36in.). A 5 foot x 7 foot would handle the volume needed. We also found that the circular screens ground the vermiculite. If we over screen it could effect the size of material and increase the waste. It is also important that the material dry in a fast time frame without applying over 120 degrees. As long as the material is wet heat won't affect it.

Vermiculite - Mineral Deposit Profiles, B.C. Geological Survey

by G.J. Simandl¹, T. Birkett² and S. Paradis³ ¹British Columbia Geological Survey, Victoria, B.C., Canada ²SOQUEM, Québec City, Québec, Canada ³Geological Survey of Canada, Sidney, B.C., Canada

Simandl, G.J, Birkett, T. and Paradis, S. (1999): Vermiculite; in Selected British Columbia Mineral Deposit Profiles, Volume 3, Industrial Minerals, G.J. Simandl, Z.D. Hora and D.V. Lefebure, Editors, British Columbia Ministry of Energy and Mines.

IDENTIFICATION

COMMODITY (BYPRODUCT): Vermiculite (± apatite).

EXAMPLES (British Columbia - Canadian/International): Joseph Lake (<u>093K 100</u>), Sowchea Creek vermiculite (<u>093K 101</u>); Libby (Montana, USA), Waldrop Pit, Enoreeg area (South Carolina, USA), Blue Ridge deposits (North Carolina, USA), Palabora deposit (Republic of South Africa).

GEOLOGICAL CHARACTERISTICS

CAPSULE DESCRIPTION: These near surface vermiculite deposits may also contain recoverable apatite. World-class vermiculite deposits occur mainly within zoned ultramafic complexes or carbonatites. Smaller or lower grade deposits are hosted by dunites, unzoned pyroxenites, peridotites or other mafic rocks cut by pegmatites and syenitic or granitic rocks.

TECTONIC SETTING: Deposits hosted by carbonatites and ultramafic complexes are commonly related to rifting within the continental platform or marginal to the platform in geosynclinal settings.

DEPOSITIONAL ENVIRONMENT / GEOLOGICAL SETTING: Mafic and ulramafic igneous or metamorphic rocks exposed to intense weathering and/or supergene, low temperature alteration.

AGE OF MINERALIZATION: Most deposits are derived from rocks of Precambrian to Jurassic age. Deposits post-date emplacement of intrusive host and regional metamorphism. Their age may be linked to periods of intense weathering which show up as erosional surfaces, paleo-regolith or unconformities.

HOST/ASSOCIATED ROCK TYPES: For major deposits the main hosts are biotitites, pyroxenites, phlogopite-serpentine rock, phlogopite-diopside±apatite rock and peridotites. Associated rock types are magnetite pyroxenites, foscorite, carbonatites, and variety of

http://www.em.gov.bc.ca/Mining/Geolsurv/EconomicGeology/metallicminerals/mdp/profiles/m 11/5/02

serpentinites that are in contact with alkali granites, syenites, fenites or pegmatites. For smaller or marginal deposits located in highly metamorphosed settings the typical host rocks are amphibolite and biotite schists in contact with pyroxenites or peridotite dykes or lenses, sometimes cut by pegmatites.

DEPOSIT FORM: Variable shapes, a function of the geometry of the favourable protolith and zone of fluid access. Semi-circular surface exposures found with deposits associated with ultramafic zoned complexes or carbonatites, usually near the core of the intrusion. Lenticular or planar deposits of vermiculite are found along serpetinized contacts between ultramafic rocks and metamorphic country rocks. Individual lenses may be up to 7 metres thick and 30 metres in length. Smaller lenses may be found along fractures and the margins of pegmatites crosscutting ultramafic lenses within high grade metamorphic terranes. The degree of alteration and vermiculite grade generally diminishes with depth. Vermiculite grades of economic interest rarely extend more than 40 metres below the surface.

TEXTURE/STRUCTURE: Vermiculite may be fine-grained or form books up to 20 cm across ("pegmatitic"). Serpentine can form pseudomorphs after olivine.

ORE MINERALOGY [Principal and subordinate]: Vermiculite ± hydrobiotite; ± apatite.

GANGUE MINERALOGY [Principal and *subordinate*]: Biotite, chlorite, phlogopite, clinopyroxene, tremolite, augite, olivine, hornblende, serpentine. In some of the deposits acicular tremolite and asbestos are reported.

ALTERATION MINERALOGY: Vermiculite is probably, in part, a low temperature alteration product of biotite.

WEATHERING: At least in some deposits, weathering is believed to play an important role in transformation of mafic minerals, mainly biotite, into vermiculite. Weathering also weakens the ore making blasting unnecessary; in extreme case it results in formation of semi- or unconsolidated, residual vermiculite deposits.

ORE CONTROLS: 1) The existence of a suitable protore, commonly dunite or pyroxenite rock containing abundant biotite or phlogopite which may be of late magmatic to hydrothermal origin. 2) Deposits occur mainly at surface or at shallow depths, but in some cases as a paleoregolith along an unconformity. 3) Vermiculite develops from periods of intense weathering or near surface alteration. 4) The maximum depth extent of the ore zone depends on the permeability, porosity, jointing and fracture system orientation which permit the circulation of meteoric fluids.

GENETIC MODELS: Vermiculite can form from variety of mafic minerals, but biotite or Febearing phlogopite are deemed key components of the protore within economic deposits.

Most of the early studies suggest that vermiculite is a late magmatic, low temperature hydrothermal or deuteric alteration product. Currently, the most accepted hypothesis is that vermiculite forms by supergene alteration due to the combined effect of weathering and circulation of meteoric fluids.

ASSOCIATED DEPOSIT TYPES: Palabora-type complexes or other carbonatites (N01) contain vermiculite mineralization. Ultramafic-hosted asbestos (M06), ultramafic-hosted talc-magnesite (M07), nepheline-syenite (R13), Ni and platinoid showings, some sapphire deposits associated with so called "crossing line" pegmatites and placer platinoid deposits (C01 and C02) may be associated with the same ultramafic or mafic complexes as vermiculite deposits.

COMMENTS: In British Columbia, vermiculite is reported from surface exposures of granite, granodiorite and quartz diorite at the Joseph Lake and Sowchea Creek showings in the Fort Fraser/Fort St. James area (White, 1990). Low grades in combination with the preliminary

http://www.em.gov.bc.ca/Mining/Geolsurv/EconomicGeology/metallicminerals/mdp/profiles/... 11/5/02

metallurgical studies indicate that these occurrences are probably subeconomic (Morin and Lamothe, 1991). Similar age, or older, mafic or ultramafic rocks in this region may contain coarse-grained vermiculite in economic concentrations.

EXPLORATION GUIDES

GEOCHEMICAL SIGNATURE: Vermiculite in soil.

GEOPHYSICAL SIGNATURE: Ultramafic rocks that host large vermiculite deposits are commonly characterized by strong magnetic anomalies detectable by airborne surveys. Since vermiculite is an alteration product of ultramafic rocks, vermiculite zones are expected to have a negative magnetic signature. However, no detailed geophysical case histories are documented.

OTHER EXPLORATION GUIDES: The largest commercial deposits usually form in the cores of ultramafic or alkaline complexes (mainly pyroxenites and carbonatites). The roof portions of these complexes have the best potential because they may be biotite-rich. Deposits derived from biotite schist are typically much smaller. All these deposits are commonly associated with some sort of alkali activity, be it only alkali granite or syenite dykes. Vermiculite deposits may have a negative topographic relief. A portable torch may be used to identify vermiculite in hand specimen since it exfoliates and forms golden flakes when heated. Therefore, an excellent time to prospect for vermiculite is after forest fires. Fenitization halos associated with alkaline ultramafic complexes and carbonatites increases the size of the exploration target. Horizons of intense paleo-weathering that exposed mica-bearing ultramafic rocks are particularly favourable.

ECONOMIC FACTORS

TYPICAL GRADE AND TONNAGE: Deposits with over 35% vermiculite (<65 mesh) are considered high grade. Most of the economic deposits contain from few hundred thousand to several million tonnes; although clusters of small, high-grade, biotite schist-hosted deposits ranging from 20 000 to 50 000 tonnes were mined in South Carolina.

ECONOMIC LIMITATIONS: World vermiculite production in 1995 was estimated at 480 000 tonnes. Major producing countries were South Africa (222 000 tonnes, mainly from Palabora), USA (170 000 tonnes) and Brazil (41 500 tonnes). In the early half of 1996 the prices of South African vermiculite imported to USA varied from US\$127 to 209 per tonne. Deposits must be large enough to be amenable to open pit mechanized mining. Large flake size (more than 65 mesh) is preferred. Both wet and dry concentrating methods are in use. Crude vermiculite is moved in bulk to exfoliation plants that are typically located near the markets. In commercial plants expansion of 8 to 15 times the original volume is typical, but up to 20 times may be achieved. The higher the degree of expansion (without decrepitation) the better the concentrates from those deposits where vermiculite coexists with asbestos or "asbestiform" tremolite are difficult to market because of the concerns over related health risks.

END USES: Agriculture 40%, insulation 23%, light weight concrete aggregate 19%, plaster and premixes 13%, other 5% (USA statistics). Other applications include carrier substrate for predatory mites in pest extermination, additive to fish feed, removal of heavy metals from soils and absorbent in poultry litter.

IMPORTANCE: Some vermiculite is derived from laterite-type deposits. Vermiculite may be substituted in concrete applications by expanded perlite or by expanded shale. Recently the use of vermiculite in cement compounds has reduced due to substitution by polystyrene. In agricultural applications it may be substituted by peat, perlite, sawdust, bark, etc. In ion exchange applications it may be substituted by zeolites.

VERMICULITE

(Data in thousand metric tons, unless otherwise noted)

Domestic Production and Use: Two companies with mining and processing facilities produced vermiculite concentrate. One company had its operation in South Carolina, and the other company had an operation in Virginia and an operation in South Carolina run by its subsidiary company. Most of the vermiculite concentrate was shipped to 19 exfoliating plants in 10 States. The end uses for exfoliated vermiculite were estimated to be lightweight concrete aggregates (including concrete, plaster, and cement premixes), 15%; and insulation, agricultural, and other, 85%.

Prepared by Michael J. Potter [(703) 648-7723, mpotter@usgs.gov, fax: (703) 648-7722]

VERMICULITE

Events, Trends, and Issues: Vermiculite use in insulation includes moderately high-temperature applications. Vermiculite is used with selective binders (sodium and potassium silicate) and compressed into blocks, boards, or special shapes. Bonded refractory boards and shapes are used as backup insulation behind hot refractory surfaces or as hot face media themselves. In lower-temperature, metal-melting industries, vermiculite can be used in contact with the molten metal and can withstand heat and flame up to 1,200° C. Vermiculite shapes are used in the aluminum industry in particular because vermiculite has a nonwetting characteristic with aluminum. Vermiculite also is used in refractory concretes, such as ramming mixes and castables.⁶

South Africa and the United States have been the largest producers of vermiculite. China had an estimated output of 40,000 tons in 2000. In Uganda, a Canadian firm, Canmin Resources Ltd., began commercial mining and production in 2001 with 2,000 tons of vermiculite being mined for stockpiling. The company expected to serve markets for insulation and horticulture in the Middle East.⁷ In Zimbabwe, Samrec Vermiculite (Pvt.) Ltd., the Imerys Group-owned operator of the Shawa Mine, was completing work to double its vermiculite capacity to more than 40,000 tons per year. Two-thirds of the production was being sold to Europe with the remainder going to Asia and the Middle East. The increased production would be marketed worldwide.⁸

World Mine Production, Reserves, and Reserve Base:

	Mine production		Reserves ⁹	Reserve base ⁹
		<u>2001°</u>

Russia	25	25	NA	NA
South Africa	209	162	20,000	80,000
Zimbabwe	19	15	ŃÁ	NA
Other countries ¹⁰	46	_40	_5,000	20,000
World total (may be rounded)	<u>46</u> 512	470	50,000	200,000

World Resources: Marginal reserves of vermiculite, occurring in Colorado, Nevada, North Carolina, Texas, and Wyoming, are estimated to be 2 to 3 million tons. Resources in other countries may include material that does not exfoliate as well as United States and South African vermiculite.

Substitutes: Expanded perlite is a substitute for vermiculite in lightweight concrete and plaster. Other more dense but less costly material substitutes in these applications are expanded clay, shale, slate, and slag. Alternate materials for loosefill fireproofing insulation include fiberglass, perlite, and slag wool. In agriculture, substitutes include peat, perlite, sawdust, bark and other plant materials, and synthetic soil conditioners.

VERMICULITE

By Michael J. Potter

Domestic survey data and tables were prepared by Nicholas A. Muniz, statistical assistant, and the world production table was prepared by Glenn J. Wallace, international data coordinator.

Vermiculite is a hydrated magnesium-aluminum-iron silicate. Flakes of raw vermiculite concentrate are mica-like in appearance and contain water molecules within their internal structure. When the flakes are heated rapidly at a temperature of 900° C or higher, the water flashes into steam, and the flakes expand into accordion-like particles. The color, which can range from black and various shades of brown to yellow for the raw flakes, changes to gold or bronze. This expansion process is called exfoliation, and the resulting lightweight material is chemically inert, fire resistant, and odorless. In lightweight plaster and concrete, vermiculite provides good thermal insulation. Vermiculite can absorb such liquids as fertilizers, herbicides, and insecticides, which can then be transported as free-flowing solids (Harben and Kuzvart, 1996).

Production

Domestic production (sold or used) data for vermiculite were collected by the U.S. Geological Survey (USGS) from two voluntary surveys—one for mine-mill operations and the other for exfoliation plants. Of three mine-mill operations, partial data were obtained from one.

Because there have only been three U.S. mining operations (two companies) of vermiculite concentrate in recent years, any vermiculite production data collected by the USGS are proprietary and must be withheld. The two U.S. producers of vermiculite concentrate were Virginia Vermiculite Ltd., with operations near Woodruff, SC, and in Louisa County, VA, and W.R. Grace & Co., from its operation at Enoree, SC.

Vermiculite concentrate was shipped to exfoliating plants for conversion into lightweight material (table 2). Output of exfoliated vermiculite sold or used in 2001, using partly estimated data, was about 140,000 metric tons (t) (table 1). Domestic production of exfoliated vermiculite sold or used was by 14 companies operating 19 plants in 10 States (table 2). Of the 19 known exfoliation plants, 9 (47%) responded. The nine operations represented 42% of the sold or used vermiculite listed in tables 1 and 3. Data for the remaining operations were estimated from previous years' production levels. States that produced exfoliated vermiculite, in descending order of output sold and used, were South Carolina, New Jersey, Ohio, Arizona, Pennsylvania, Florida, Arkansas, Illinois, Texas, and New Mexico.

W.R. Grace & Co. voluntarily filed for reorganization under chapter 11 of the U. S. Bankruptcy Code in response to a sharply increasing number of asbestos claims against the company. Grace's asbestos liabilities largely stem from commercially purchased asbestos added to some of its fire protection products; the company ceased to add any asbestos to its products in 1973. The filing would enable the company to operate in the usual manner under court protection from its creditors and claimants while developing and implementing a plan for addressing the asbestos-related claims against it (W.R. Grace & Co., 2001b§1).

Legislation and Government Programs

The U.S. Environmental Protection Agency (EPA) continued to test for the presence of asbestos in and around a former vermiculite mine, the local environment, and homes in Libby, MT. The mine was shut down in 1990. The agency also was continuing to assess the risk posed by exposure to the Libby material. Reports on the epidemiological and monitoring activities were available on the website for EPA region 8 (U.S. Environmental Protection Agency, 2002§).

The EPA issued a report investigating whether any of the mineralogical and chemical characteristics of vermiculite products might serve as tracers to help regulators identify product sources. Interest in tracking sales of vermiculite products arose because of the presence of asbestos in some of the Libby, MT, vermiculite products that were sold in the past. The objective of the EPA report was to form the groundwork for additional studies on tracer components. Two of the more promising areas for future study were compositional variations in amphiboles and micas and trace element variations in the ores from different locations. The study recommended various methods of analysis for further study and a sampling protocol (Frank and Edmond, 2001).

Consumption

Vermiculite has a wide range of uses that take advantage of its attributes, such as low density, good insulating properties, inertness, fire resistance, and high liquid absorption capacity. Vermiculite is used in general building plasters either in its own formulations or combined with such other aggregates as perlite. Specialist plasters include fire protection and acoustic products in which vermiculite is combined with a binder, such as gypsum or portland cement, plus fillers and rheological aids (Roskill Information Services Ltd., 1999, p. 72-76).

Exfoliated vermiculite treated with a water repellent is used to fill pores and cavities in masonry construction (especially hollow blockwork) to enhance fire ratings, insulation, and acoustic performance. Exfoliated finer grades of vermiculite are used to produce insulation shapes. The manufacturing process is very similar to that used for the production of silicate-bound building boards (Roskill Information Services Ltd., 1999, p. 84). Vermiculite-based insulation shapes can be used in lower temperature metal-melting-processing industries; vermiculite can be used in contact with molten metal up to 1,200° C. Vermiculite shapes are used in the aluminum industry, in particular, because vermiculite is said to have a nonwetting characteristic with aluminum (Russell, 2000, p. 16).

Exfoliated vermiculite has been combined for many years

¹References that include a section twist (§) are found in the Internet References Cited section.

with high alumina (also known as aluminous or calcium aluminate) cements and such aggregates as expanded shale, clay, and slate to produce refractory and/or insulation concretes and mortars. These are used in areas where strength and corrosion/abrasion resistance are of secondary importance; the most important factor is the insulation performance of the inplace refractory lining. These mixes are used in such industries as iron and steel, cement, and hydrocarbon processing (Roskill Information Services Ltd., 1999, p. 85).

In horticulture, exfoliated vermiculite improves soil aeration and moisture retention. When vermiculite is mixed with peat or other composted materials, such as pine bark, the resulting product provides a good growing medium for plant propagation. As a soil conditioner, exfoliated vermiculite can improve the aeration of "sticky" soils and the water holding characteristics of sandy soils. This allows for easier watering and reduces the likelihood of cracking, crusting, and compaction of the soil. Vermiculite is used in the fertilizer/pesticide market because of its ability as a carrier, bulking agent, and extender (Roskill Information Services Ltd., 1999, p. 81, 90-91).

Finer grades of exfoliated vermiculite are used to partially replace asbestos in brake linings primarily for the automotive market (Roskill Information Services Ltd., 1999, p. 84).

Prices

Published prices for vermiculite serve only as a general guide because of variations in source, quantity, application, and other factors. Prices for raw (unexpanded) U.S. vermiculite concentrate, bulk, ex-mill were unchanged from 2000—from about \$143 per metric ton to \$220 per ton, depending on particle size. For imported South African crude vermiculite, bulk, free on board barge, U.S. Gulf Coast, prices ranged from \$187 per ton to \$243 per ton (Industrial Minerals, 2001c).

The average value of U.S. exfoliated vermiculite sold or used by producers, using partly estimated data, was \$340 per ton (table 1), which was a composite value including both U.S. and imported material.

Foreign Trade

Trade data for vermiculite concentrate are not collected as a separate category by the U.S. Census Bureau but are included within the basket category "vermiculite, perlite, and chlorite, unexpanded" under tariff code 2530.10.0000. According to Moeller (2002), U.S. exports of vermiculite concentrate in 2001 were about 7,000 t (table 1). Total U.S. imports of vermiculite in 2001 were about 65,000 t (Port Import/Export Reporting Service, unpub. data, 2002). South Africa supplied about 73% of the tonnage, and China, 25%.

World Review

In Western Europe, an estimated 55% of exfoliated vermiculite was going into proprietary products used in construction of commercial and industrial structures, including building boards, general construction plasters, and specialist fire protection/acoustic plasters (Roskill Information Services Ltd., 1999, p. 3).

Australia.—Index Ltd., based in Perth, Western Australia, was planning to sell its mining concern Australian Vermiculite Industries. The operation is the country's only vermiculite producer; the mine is located 160 kilometers northeast of Alice Springs in the Northern Territory. Output was about 10,000 to

12,000 metric tons per year (t/yr), which was supplying 80% of the domestic market as well as being exported to Europe, Japan, the Middle East, New Zealand, and Taiwan. Markets were fire protection, building products, and horticulture (Industrial Minerals, 2001a).

China.—Although data were not fully available, output of vermiculite was estimated to be at least 30,000 to 40,000 t/y from the four main producers in Xinjiang Province. An additional 15,000 t of output (not listed in table 4) was estimated to have been produced in Hebei Province (Moeller, 2002). Hebei Metals & Minerals Import and Export Corp. (Hebei Minmetals), which deals with metals, minerals, and other products in Hebei Province, classifies vermiculite into two types. Silver-white vermiculite contains 5% to 13% iron oxide (Fe₂O₃) and is for use in the construction industry. Golden yellow vermiculite, with 16% to 22% Fe₂O₃, is used in agriculture and horticulture. Export destinations for Chinese vermiculite included Japan, the Republic of Korea, and North America (Li, 2001).

South Africa.—Reported production of vermiculite in 2001 was 156,632 t, a 25% decrease from that of 2000. Production at Palabora Mining Co. Ltd., the world's largest vermiculite producer, was hampered by wet in-pit mining conditions and low availability of plant and heavy equipment (Profile Data, 2002§). New management, dryer weather conditions, and improvements at the mine and mill could allow increased production in 2002 (Moeller, 2002).

Uganda.—Canmin Resources Ltd. began mining and production at its Namekara vermiculite project in the Mbale District of southeast Uganda. Canmin is a wholly owned subsidiary of Canadian junior mining and investment company IBI Corp. Some 2,000 t of vermiculite was being mined for stockpiling, and processing equipment had been installed in a newly constructed processing building. Canmin's target output was around 40,000 t/yr of vermiculite for insulation and horticulture, which would be exported to Europe and the Middle East (Industrial Minerals, 2001b). Also, prospective customers in Canada and the United States were assessing the feasibility of using the large-flake, coarse-grade vermiculite for similar purposes (Mining Journal, 2001).

Zimbabwe.—Samrec Vermiculite (Zimbabwe) (Pvt.) Ltd. (the Imerys-owned operator of the Shawa mine) was doubling its vermiculite capacity to 40,000 t/yr. Also, the plant was being automated, which would reduce production costs. The basis for the plant expansion was demand for large-flake vermiculite, of which Samrec was one of only a few producers worldwide. Two-thirds of the current production from Shawa was being sold to Europe, with the remainder going to Asia and the Middle East. The increased production would be marketed worldwide; some of the product was being tested in North America (Industrial Minerals, 2001d).

Outlook

Besides traditional end uses, such as horticulture, including potting soils, soil amendments, and as a fertilizer carrier, vermiculite is being used increasingly in other areas. One use is as an intumescent (swelling) material used, for example, in firerated building products where its expansion qualities under fire prolong the products' structural integrity; another example is use in composites where its intumescent action provides an insulating thermal barrier (W.R. Grace & Co., 2001a§). Another application is in dispersions of vermiculite in water produced by the chemical exfoliation of vermiculite for various coatings and film-forming applications (Hindman, 1994). These films improve the fire resistant properties of such industrial products as gaskets and automotive seals for catalytic converters (Roskill Information Services Ltd., 1999, p. 86).

In China, vermiculite production capacity is said to be increasing at a significant rate (not reflected in table 4); about 80% of the output is being exported. China appears to be emerging as a major supplier of vermiculite (Moeller, 2002).
