GEOLOGICAL REPORT ON THE PROTEUS RESOURCES INC. RUBY VALLEY PROPERTY 1986 NORTH COBALT, ONTARIO

BY ROBERT CINITS

Proteus Resources Inc. is the present owner of a group of 15 leased and patented claims in Lorrian Township, district of Timiskaming, 45 km southeast of North Cobalt Ontario. The property is contiguous to the Silverside Resources claim group. During the period of May 14, 1986 to September 11, 1986 a mineral exploration program was carried out aimed at silver and gold mineralization. This involved 10,060 feet of diamond drilling (core size BQ), and 3 days of EM-37 geophysics. Drilling was performed by Barron Diamond Drilling and the geophysics was operated and interpreted by Quantech Consulting Inc. The core is stored on covered racks nearby the property on claim T-25683 (mining rights owned by Silverside Resources, surface rights owned by Peckover). A total of 514 split core samples were sent to Bell White for assay (292 Au + Ag, 22 Ag only, 200 Au only). As well 4 of the 16 holes had sludge samples taken every 10 feet and assayed for silver.

The reports describes the location, geology, structure and mineralization encountered on the property and recommendations for further exploration.

The report is based upon:

1) the records of the 1984, 1985, and 1986 exploration programmes of Proteus Resources Inc.
2) geological reports and maps of the O.G.S. and maps of the O.G.S. and O.D.M.
3) the records of the 1960's exploration program by the Timiskaming Project Syndicate, and the 1979 exploration program by Teck Explorations Ltd.
4) personal communication with geologists from Proteus Resources Inc. and Silverside Resources Inc.

Property and Location

The Proteus Resources Inc. property is located in Lorrain Township, in the District of Timiskaming, Ontario. There are a total of 15 contiguous claims which together make up 240 ha. of land. The claims are all leased except for two which are patented. The surface rights to the land are divided between G. Peckover, G.L. and L.W. Peddie, the Crown, and Proteus Resources Inc. The claim numbers are as listed below and located as on fig 3.

Claim Number	Area (ha)	Surface Rights
Patented Claim SE/4, N/2 Lot 1, Con 12	16	G.L. & L.W. Peddie
Patented Claim NE/4, S/2 Lot 1, Con 12	16	G.L. & L.W. Peddie

T-27793	16	Proteus Resources
T-46861	16	Crown
T-46862	16	Crown
T-3591	16	G. Peckover
T-11627	16	Proteus Resources
T-31635	16	Crown
T-25997	16	Proteus Resources
T-25661	16	Proteus Resources
T-31634	16	Crown
T-27828	16	Proteus Resources

Access and Facilities

Access to the property is made from Highway 11B in North Cobalt at which point one travels approximately 2.5 km southeast on Highway 567 until a gravel service road is reached. This leads to the Silverside Resources ramp and the Proteus Property. Travelling south on the road one comes to the Proteus core shack at approximately 2.2 km. The property boundary is located 0.7 km further south along the road. (see Figs.1 & 2)

Many rough drill roads run across the property making easy access to all areas by foot or Ski-doo in the winter.

A creek traverses much of the claim group, supplying adequate water for diamond drilling in both the summer and winter months.

Should further development of the property be required, it is closely located to roads and towns (Cobalt, Haileybury, New Liskeard) with available mine supplies and milling services.

Topography and Physiography

The property displays a wide variety of topography and surface conditions. Much of the north portion has moderate relief with poplar as the dominant vegetation. Overburden, in this area, ranged from 0 to 49 feet with the deepest values occurring in the vicinity of the N-S trending fault. A southeast trending creek traverses the middle of the property. This is surrounded by areas of open field and swamp to the south.

The south portion of the property is characterized by swampy ground with thick poplar and birch vegetation. An abrupt northwest trending ridge covers most of the extreme south and southwest of the claims. Overburden ranges from zero along the ridge thickening to over 120 feet in the swamp.

Regional Geology

The best descriptions of the geology, mineralogy, and ore deposits of the Cobalt Silver Camp can be found in publications by the O.D.M and O.G.S (Knight 1922, Thompson 1960, and O.D.M Map 2050).

The Cobalt area consists of three main rock types: Keewatin Volcanics, Huronian Sediments, and Nipissing Diabase. Historically silver has been found in all three, occurring as short veins which pinch and swell from a few tenths of an inch to over a foot.

The oldest rocks are the Keewatin greenstones and interflow sediments. These are steeply dipping with a general east-west trend. Rock type varies a great deal throughout the region from basalt to rhyolite as flows and pyroclastic units.

The volcanics are unconformably overlain by relatively flat lying Cobalt Series Sediments. These consist of conglomerate, greywacke, quartzite and argillite. Deformation within these units is quite minimal.

Both the volcanics and Sediments are cut by the Keeweenawan aged Nipissing Diabase Sill. This is somewhat flat lying, but creates several arches and basins as it slices through the other rock types.

Extensive faulting characterizes the region with a series of northwest trending faults dominating. These are the Lake Tamagamee Fault, the McKenzie Fault, and the Cross Lake Fault. Locally many other smaller faults of various orientations are present.

Property Geology

The Proteus Resources property contains outcroppings of the three main rock types common to the Cobalt area. Nipissing Diabase outcrops along the extreme west, north and southeast borders of the claim group and dips to form a northeast trending basin in the center of the property. This is overlain by Keewatin Volcanics, which in turn is unconformably overlain by Cobalt Sediments.

The Volcanics only outcrop along the ridge on the southwest corner of the property. Their lithology varies a great deal from the north of the property to the south, and all are of greenschist metamorphic grade.

In the north they consist mainly of steeply dipping units of rhyolite to porphyritic rhyolite with local variations in color from black to grey to red. These units tend to grade into each other with no distinct contact. The heavily porphyritic units contain phenocrysts of anhedral to euhedral quartz and feldspar. Locally, the volcanics are moderately to intensely fractured and brecciated, primarily in the vicinity of faults. Lamprophyre, diabase and other mafic dikes occur as small swarms and individual dikes ranging from several inches to over 10 feet in width.

The volcanics in the south of the property include steeply dipping beds of rhyolite to quartz and feldspar porphyritic rhyolite to rhyolite breccia, intercalated with irregular and discontinuous beds of mafic to intermediate tuff to lapilli tuff to agglomerate. The general strike of the units is north-west, dipping steeply to the south. Thickness of the beds range from several feet to several hundred feet. As in the north, many late lamprophyre and diabase dike cut the lithology in the south portions of the property.

The Cobalt Sediments outcrop over much of the northeast and extreme southwest portions of the property. Most of the sediments are of the Coleman Formation which includes conglomerate, greywacke, pebbly-wacke, argillite, siltstone and arkose. Drill hole data indicates a general grain size increase with depth from banded argillite to conglomerate. All beds are close to horizontal and relatively undeformed.

A small outcrop of quartzite from the Lorrain Formation occurs on the extreme east and southwest borders of the claim group. The Cobalt Sediments thicken dramatically in the north portion of the property, as one moves east. Here, thicknesses well over 250' were encountered.

Structural Geology

A large subvertical north trending fault has been identified by geological field mapping and diamond drill hole data. It traverses most of the property and at occurs as an intensely brecciated and fractured zone cemented with white calcite.
Another northwest trending fault occurs in the south portion of the property. It is dipping at about 40° to the southwest and is slighty offset by another small north trending fault.

History

The Proteus Resources Inc. property is located within the Cobalt Silver Camp, directly south of the recent Silverside Resources Inc. discovery. Since the early 1900's the Cobalt area has produced over 750,000,000 ounces of silver, making it one of the richest silver producing areas in the world.

The property and its near vicinity have been explored since the early 1900's. The surface is dotted with small exploration pits and trenches indicating many uneconomic but interesting veins.

The first documented exploration on the Proteus claim group occured in the 1960's by the Timiskaming Project Syndicate. They performed a geophysical survey which showed several anomalies across the property. Many of these were drilled and returned, very encouraging results ranging from 1.00 oz/ton Ag to 19.79 oz/ton Ag in all three main rock types. They drilled a total of 22 holes, most being in the north portion of the property. No further work was done by this company.

In 1979 Teck Explorations Ltd. optioned claims T-31635, T-46861,T-46862 and T-11627, and performed EM-15, VLF, and Magnetometor surveys. Minor anomalies were detected, but nothing substantial was indicated after mapping and surface sampling were completed. The claims were allowed to lapse.

In September 1984, Proteus Resources Inc. started an exploration program on the claim group. Two grids were cut: one in the north on claims T-27828, T-25997, T-3591, and T-27793, and one in the south on claims T-31635 and T-46862. The property was then mapped and sampled. In August of 1985 they started a diamond drilling program in hopes of reproducing and improving results obtained by the Temiskaming Project Syndicate in the 1960's. A total of 9,261 feet was drilled in 15 holes, 11 on the north grid and 4 on the south grid. Unfortunately, few significant results were obtained in the areas where the earlier drilling had its success. However several anomalous silver and gold results in the North Zone warranted further exploration. Most notable were values of 2.00 oz/ton Ag (sludge) over 10 feet and 0.142 oz/ton Au over 0.8' both in hole P-85-15. They also drilled 4 holes in the south previously unexplored by diamond drilling. Several zones of NW trending pyrite rich flow breccia bands were intersected that carried anomalous amounts of silver and gold. Several gold values ran in the 0 .036 oz/ton to 0.044 oz/ton range.

Once again further exploration was warranted. In January 1986 another drilling project was started on the property to follow up on the results from the 1985 drilling. From January 10, 1986 to February 28, 1986 a total of 24 holes were drilled by 3 units (core size BQ) amounting to 12,534 feet.

The best silver value was obtained from hole P-86-13 which interected a 1/4" pink carbonate vein with 70% cobalt arsenides. The vein assayed 13.55 oz/ton Ag over 0.3 feet. Many other interesting but uneconomic silver values were intersected. In both the rhyolite and breccia units (see appendix for further assay results).

The core was also tested for gold mineralization, with the best values being in the range of 0.03 oz/ton Au to 0.08 oz/ton Au. The best gold intersection occured in hole P-86-23 where a pyrite seam assayed 0.374 oz/ton Au over a true width of 0.3 feet.

Current Exploration

On May 14, 1986 another diamond drilling prject was started on the Ruby Valley Property. Barron Diamond Drilling was contracted to drill BQ size core and the total footage came to 10,060 feet.

Most of the project concentrated on the south zone aiming at both silver and gold mineralization. Several holes were drilled to determine the orientation of the cobalt-arsenide vein intersected in P-86-13. The vein was intersected several times over a strike length of about 400', giving a strike of 84° to the east and a near vertical dip (see Silver Vein Longitudinal Section). Unfortunately the vein remained very narrow (<1/2") with interesting but uneconomical Ag values. All of the intersections occured in the volcanics, in both rhyolite and intermediate breccia, close to the upper contact of the Diabase Sill. The best value intersected in the vein came from hole P-86-28 where 23.34 oz/ton Ag over 0.5' was obtained.

Besides this vein, several interesting Ag values were intersected in drill holes which appear to be related to different vein systems. Of note are the following:

P-86-29	4.10 oz/ton Ag/0.5'
P-86-33	4.81 oz/ton Ag/0.5'

Once again many anomalous gold values were also returned.

As a result, the drilling was temorarily halted in July for two weeks in an attempt to evaluate the possibilities of significant gold mineralization occuring on the property. during this time 200 five foot samples were assayed for gold, taken from previous holes in the vicinity of anomalous gold valus, intense alteration, and sulphide mineralization. The best results are as follows:

P-86-23	0.18 oz/ton Au over 1.9'
P-86-27	0.097 oz/ton Au over 2.5'
P-86-30	0.086 oz/ton Au over 1.0'

The gold results obtained from the property to date are summarized on table 2 appendix.

At the end of the drill program a test grid was constructed directly over the silver bearing vein and 4 lines of EM-37 were performed by Quantech Consulting Inc. Final results of this are unavailable at the time of this report.

Economic Geology

Silver

Most of the exploration in the Cobalt Camp has concentrated on silver, and this would have to be considered the primary target on the Proteus Property. Most of the claims are located over a diabase basin which dips to a depth of over 500 feet in the center of the property below Keewatin Volcanics and Huronian Sediments. Therefore we are concerned with "Upper Contact Mineralization:", very similar to the silver deposits of Silver Center in South Lorrain Township.

Several faults are present across the property especially in the vicinity of the vein intersected in the south zone. These may be an important controlling factor in the deposition of silver in the area.

Another encouraging feature of the property are the pyrite rich zones of breccia which may have acted as a conduit for silver bearing fluids to permeate into nearby host rocks.

The best silver values have occured in pink and white carbonate veins with associated cobalt arsenide mineralogy. Other less significant silver values have been found in the pyrite rich breccia with associated chalcopyrite, galena, hematite and magnetite. Alteration around the silver bearing veins is very minor with chloritization and carbonatization prevailing.

Fig 5

Gold

Most of the gold mineralization on the Proteus Property appears to epigenetic and structurally related to the northwest trending fault in the south zone. Hydrothermal fluids originating from an external source likely flowed through the depositional environment and precipitated gold. Permeability for focussed fluid flow is create by deformation as a component of the northwest trending structual system.

Much of the gold mineralization occurs in narrow discontinuous zones concordent with the lithology and hence parallel to the fault. The rock surrounding the fault has been deformed to varying degrees depending upon the distance form the fault and the lithology.

Brittle deformation tends to dominate in the areas where rhyolite and quartz-feldspar porphyritic rhyolite are present. This results in numerous irregular fractures and cataclastic destructuion and brecciation of the rock. Consequently the permeability of the rock is increased allowing mineralized fluids to crystallize as fine disseminated specks and anhedral blebs of pyrite throughout the fractures and in samll quartz-carbonate veins. Associated mineralogy includes chalcopyrite, magnetite, and hematite. The gold tends to be directly related to the pyrite. In the softer and less competent mafic to intermediate tuffs and breccias, ductile deformation occured without rupture of the rocks and therefore open fissures are less prevalent. Instead fluid flow is carried along penetrative fabrics and crystallized as pyrite and minor chalcopyrite. Once again gold is related to the pyrite and best values occur in areas with the highest percentage of pyrite.

Alteration is not overly intense in the south zone. In the rocks where brittle deformation has occured the secondary mineral assemblages are primarily confined to grain boundaries and interstitial voids due to a less reactive mineralogy and more competent response to deformation. Where as in the slightly more reactive and relatively incompetent mafic to intermediate rocks alteration tends to be slightly more pervasive.

Chloritization is the most widely extensive alteration and occurs as fine specks and irregular dots throughout much of the rock, especially in the vicinity of faulting.

It also forms small borders around quartz and carbonate veins.
Zones of intense red potassic and hematite alteration occur as haloes surrounding lamprophyre and diabase dikes and quartz-carbonate veins.
In the porphyritic varieties of rock, areas of extensive epidote alteration exist where euhedral feldspar phenocrysts have been completely replaced by light green epidote.
Minor silicification and carbonatization are present throughout, but especially in the vicinity of sulphide mineralization.

Conclusions

The results of the 1986 drilling program indicated a narrow pink carbonate vein in the south zone of the property. The vein was traced over a strike length of about 400 feet however silver values remained sub-economic with the highest value being 23.34 oz/ton Ag overr 0.5'. Several other anomalous silver values were obtained from other veins, but their orientations could not be determined.
Many interesting gold values were also returned from the project. Gold mineralization appears to be epigenetic and structually related to a northwest trending fault. Gold is directly associated with pyrite mineralization in narrow discontinuous zones which are sub parallel to the fault and lithology. Most of the values were very "spotty" and sub-economic.
A program of resampling of previously drilled pyritiferous zones was conducted in an attempt to find new gold bearing zones or extend the original ones. A total of 200 -5 foot samples were taken with minimal significant results.

Recommendations

As a result of the exploration work performed over the property during the past year, any further exploration should examine new areas of the property and concentrate on silver. A small program of soil sampling and geophysics (EM-37) would be helpful in determing possible targets for drilling.

Certificate

With respect to my report on the North Cobalt, Lorrain Township property for Proteus Resources Inc. I, R. A. Cinits do hereby state that:

1. I am a geologist presently employed by Proteus Resources Inc.
2. I am a graduate of the University of Toronto where in 1985 I received my Honors B.Sc. Degree, Specialist Geology.
3. I have no present or past interest in the property described in this report.
4. This report is based on geological reports and maps prepared from records of the 1984, 1985, and 1986 exploration programmes, records of companies previously involved in exploration on the property, reports and maps prepared by the O.G.S. and O.D.M. and personal communication with geologists involved in work on the property.
