1.0 SUMMARY:

H.E. Neal & Associates Ltd. were contracted to conduct a geological survey over the 101 group of claims in Holloway Township by Mr. H.E. Neal. The survey was conducted on a grid cut by the Jean Alix Company Ltd. during March, 1982.

Less than 2% of the claim group is covered by outcrop resulting in a heavy reliance on magnetometer data for a geological interpretation. All outcrops occur south of the Mattawasaga River.

A geological interpretation shows that the rocks trend in a northeast direction as bands. From north to south they include sediments, mafic to ultramafic volcanics and intermediate to mafic volcanics.

No quartz/carbonate veining was observed.

The area has potential for gold mineralization. Two areas of potential interest have been identified. The first area in the northwestern portion of the property was identified because of possible structure and gold values obtained from previous drilling.

The second area located in the south-central area of the property was identified from a combination of potential structure and lithology and from gold values obtained from previous drilling.

2.0 INTRODUCTION:

H.E. Neal & Associates Ltd. were contracted to conduct a geological survey over 10 claims held by Mr. H.E. Neal in Holloway Township. All 10 claims are being submitted for assessment credits.

The Jean Alix Company Ltd. was sub-contracted to cut and chain 10.4 miles of lines which included an east-west baseline 9,000 feet in length. Cross lines were cut every 400 feet.

The geological survey was conducted by one geologist during part of August, 1982.

3.0 THE PROPERTY:

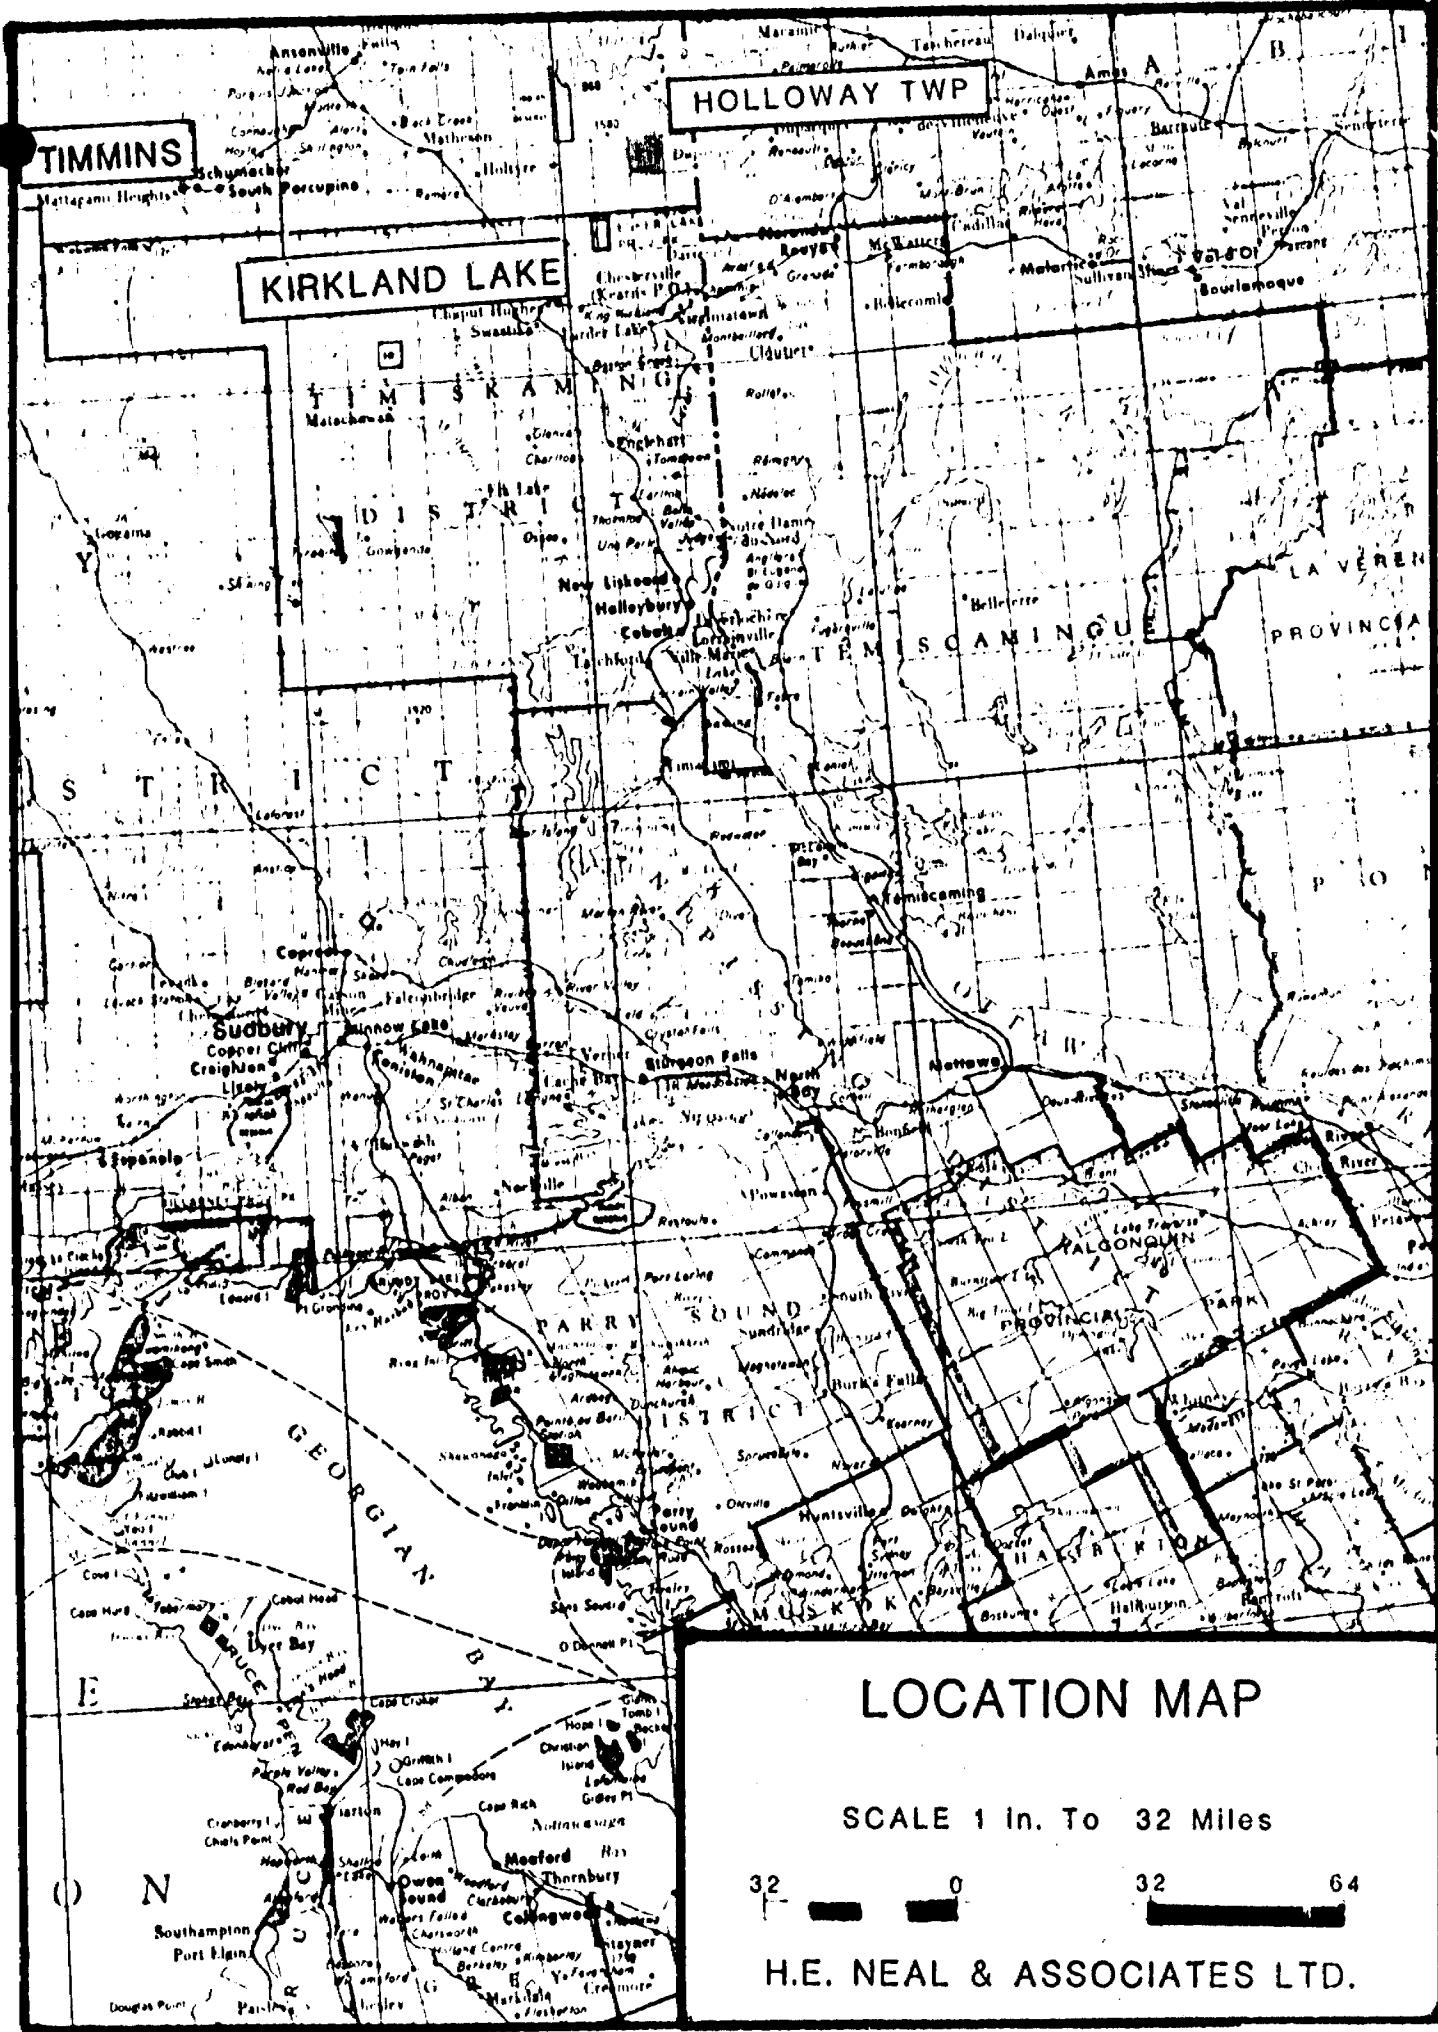

The property consist of 10 contiguous claims in Holloway Township.

The claims are held by H.E. Neal, 124 Roxborough Drive, Toronto, Ontario.

The claims are listed below:

L598637 to L598646 inclusive.

2 M.

101 GROUP
HOLLOWAY TOWNSHIP
PROPERTY MAP

SCALE 1 To 1/2 Mile

H.E. NEAL & ASSOCIATES LTD.

4.0 LOCATION AND ACCESS:

The 10 claims are located on Holloway Township, District of Cochrane, in the Larder Lake Mining Division.

The west side of the claim group is located 26 miles north-east of the town of Holtyre.

Access to the property is east along Highway 101 to Holloway Lake in Holloway Township. The claims are located 700' south of the Highway at this point and are accessible by foot.

5.0 PREVIOUS WORK:

1949 - Lobanor Gold Mines Limited drilled 5 diamond drill holes totalling 5,129 feet. Four were drilled on claims held by H.E. Neal.

1960 - Revere Mining Corporation Ltd. conducted ground magnetic and electrical resistivity surveys over claims held by them. Work also included 7 drill holes totalling 3,121 feet. This work also included claims now held by H.E. Neal.

1952 - J. Satterly from the Ontario Department of Mines mapped the northern part of Holloway Township which also includes the H.E. Neal claims.

1982 - H.E. Neal & Associates Ltd. conducted ground magnetometer and VLF-EM surveys over the entire claim group area.

6.0 LINE CUTTING:

The Jean Alix Company Ltd. of Val D'Or, Quebec, was sub-contracted to cut and chain 10.4 miles of picket lines which included an east-west baseline 9,000 feet in length. Cross lines were cut every 400 feet perpendicular to the baseline. The work was completed during March, 1982.

7.0 GEOLOGY:

7.1 General Geology

The rocks in Holloway Township are Archean in age and belong to the Abitibi Sub-Province of the Superior Province. The rocks are mainly Keewatin andesite and basalt with some interflow sediment. A wide band of sediments occurs roughly parallel to Highway 101 across the township. The northwestern part of the township is underlain by mafic to ultramafic intrusives that make up part of the Ghost Range Syncline.

The rocks face south and dip south at 80° or steeper. The rocks generally trend east north-east.

The major structural feature in the township is the Destor Porcupine Fault Zone which is roughly parallel to and in the vicinity of Highway 101. Some cross faulting does occur in the township but is usually obscured by extensive overburden.

The overburden covers approximately 80% of the township and has reported thickness up to 150'.

A table of formations from Satterly (1953) is shown on the following page:

TABLE OF FORMATIONS

CENOZOIC

RECENT: Peat; stream deposits.
PLEISTOCENE: Sand, Gravel, Boulders; varved clay.
Great unconformity

PRECAMBRIAN

KEWEENAWAN: Quartz diabase
Intrusive contact
MATACHEWAN: Quartz diabase, diabase.
Intrusive contact
ALGOMAN: Feldspar porphyry; felsite; lamprophyre.
Intrusive contact
PRE-ALGOMAN: Diabase, gabbro; peridotite and dunite (serpentinized);
pyroxenite.
Intrusive contact
KEEWATIN:
(Rhyolite; rhyolite agglomerate and tuff.
(Andesite, basalt; pillow lava; diabasic lava;
Volcanics: (spherulitic lava; fragmental lava (flow breccia
(or agglomerate); tuff and chert; talc-chlorite
schist; carbonate-chlorite schist.
Faulted contact
Sediments: Greywacke, slate; conglomerate; iron formation.

J. Satterly (1953).

7.2 Geology of the Claim Group

Less than 2% of the claim group area is exposed by outcrop all of which occurs south of the Mattawasaga River. This has resulted in a heavy reliance upon the magnetic data to produce a geological interpretation.

Outcrop is generally confined to the south-eastern half of the property. All of the outcrops form steep ledges.

The rocks are comprised of pillowd to massive intermediate volcanics with one occurrence of flow breccia or agglomerate. The rocks strike to the northeast and exhibit steep dips to the south.

From outcrop and drill hole evidence it appears that the low magnetics underlying the southern half of the claim group are due to intermediate and mafic volcanics. The small magnetic high on lines 72E and 76E in claim L598645 is likely a small mafic intrusion.

North of these, two close spaced, parallel bands of magnetic highs occur. The bands are probably due to mafic to ultramafic flows and/or sills that are common in the area.

A band of low magnetics occurs at the extreme north of the claim group area. This is probably produced by sediments, the southern contact of which might be the Destor Porcupine Fault Zone or the Ghostmount Fault. These are the two major strike faults in the Township. The

sediments are thought to be sheared and probably lie within the Destor Porcupine Fault Zone.

7.2.1 Pillowed Lavas

Pillowed basalt or andesite is the most common rock type that occurs in outcrop. It generally forms precipitous outcrops commonly with convoluted surfaces and weathers to a light brown or brownish grey.

Fresh the rock is greenish grey, very fine grained and weakly to non-magnetic. Sulphides in the form of pyrite and pyrrhotite are very fine grained and widely disseminated. Quartz filled amygdules are common locally as are quartz filled radiating fracture patterns within the pillows. The pillows range in size from approximately one foot to greater than 3.5 feet in diameter. Pillow rims are generally a light grey colour, approximately $\frac{1}{2}$ to 3/4 inch in diameter, and may be impregnated with quartz/calcite. A vuggy appearance on the weathered surface is probably due to weathered calcite.

Pillow tops face southeast and possess steep dips of approximately 85° .

Fractures meander along pillow boundaries but generally occur at 146° - 152° / 46° - 63° NE and 69° - 78° / 54° - 64° SE.

7.2.2 Massive Basalt/Andesite

With the exception of a massive appearance this rock closely resembles

the pillow lavas. The rock is fine grained although generally coarser grained than the pillow lavas and contains pyrite crystals up to 1/8" in diameter. Pyrite is not abundant. The rock is a light bluish green, weathers to a tan or light brown colour and is weakly to moderately magnetic. Contact between the massive and pillow lavas were not observed. Fracturing was observed as follows:

72° - 89° / 75° - 77° SE, 167° - 176° / 32° - 72° NE and

128° - 139° / 62° - 69° NE.

7.2.3 Agglomerate or Flow Breccia

Only observed in one location this unit is positioned between massive and pillow lavas. The rock contains monomictic angular, unorientated fragments attaining ten inches in diameter, although averaging one to two inches. Fresh, the unit is bluish grey but weathers to a light brown. Sulphides are absent. A width of at least five feet was observed.

The unit's position between massive and pillow lavas suggests it could be a flow top breccia. However, the lack of oriented fragments and a small percentage of matrix suggests an agglomerate.

7.3 Structure

From the geological interpretation it appears that two major directions of faulting have occurred. These strike in a NE-SW and NW-SE direction

and correlate well with the 146° - 152° / 46° - 63° NE and 69° - 78° / 54° - 64° SE fracture directions observed in outcrop.

A third fracture direction bisects the previous two and strikes northwest at approximately 96° .

A fault striking roughly north-south may occur on L68E south of the Mattawasaga River. However, the presence of granitic intrusives in local drill holes suggests the deep embayment within the low magnetics may be caused by a small granitic stock. If so, the presence of gold mineralization in nearby drill holes is very encouraging.

All the aforementioned faults would appear to bisect the Destor Porcupine Fault. No evidence of the Destor Porcupine Fault is apparent from either the geology or geophysics. Magnetically the fault would be difficult to recognize as it parallels the adjacent magnetic location. Secondly the zone is thought to pass just to the north of the property.

7.4 Comparison With the VLF-EM Data

Comparison of the geological and magnetic data with the VLF-EM data suggests that outcrops are responsible for conductors H-2 and H-5. Conductors H-3 and H-6 may be the result of conductive overburden or some other buried topographical feature. Conductor H-1 may represent the geological contact between sediments and mafic to ultramafic rocks. It may also represent the southern boundary of the Destor Porcupine Fault zone or the Ghostmount Fault.

Conductor H-4 appears to parallel the contact between alders and spruce grove and may be due to surficial features.

7.5 Surficial Geology

The overburden consists mainly of glacial lake clay in the low-lying areas and of outwash deposits and moraine in the higher areas. The lake clay overlaps the glaciofluvial deposits. Clay and silt deposits have formed in the Mattawasaga River valley. Extensive deposits of peat have formed beneath the muskeg.

8.0 CONCLUSIONS:

The geological and geophysical surveys in combination with previous diamond drill hole data indicates two potential areas for gold mineralization.

The first occurs in the northwestern portion of the grid approximately around lines L16E and L20E. Previous drilling by the Revere Mining Corporation Ltd. obtained a best assay of 0.26 Au per ton over 5 feet within mafic and pyroclastic flows. The northeast striking Ghostmount Fault has been interpreted to pass through the western portion of the property. The intersected gold mineralization may be related to the Ghostmount Fault. If so the area represents a prime target area.

The second area of interest occurs south of the Mattawasaga River between lines L68E and L76E. A deep embayment of low magnetics occurs possibly due to faulting, granitic intrusion or a combination of the two. Previous drilling by Lobanor Gold Mines Ltd. and Revere Mining Corp. Ltd. intersected some gold mineralization.

Further definition of the potential target areas would be useful. A more detailed magnetometer survey would help outline structure within the area. A down ice overburden drill program might also prove beneficial.

Dear Sir:

We have received reports and maps for a Geological Survey submitted under Special Provisions (credit for Performance and Coverage) on Mining Claims L 598637 et al in the Township of Holloway.

This material will be examined and assessed and a statement of assessment work credits will be issued.

Yours very truly,

E.F. Anderson

Dear Sir:

Enclosed please find the following property reports submitted for assessment work credits by H. E. Neal & Associates Ltd. on behalf of Mr. H. E. Neal.

2 copies - Geological Survey and Linecutting performed on the 101 Claim Group, Holloway Township, Larder Lake Mining Mining Division, Matheson Area, Ontario (2 geological maps - scale 1" to 200' accompany each report).

Please note that Mr. C. Curry is the author of the report, but is no longer with H. E. Neal & Associates Ltd. and is not available to sign the report. The reports have been signed by me for Mr. Curry. If there are any problems because of this change, please let me know at the above address.

Respectfully submitted,

Peter G. Atherton B.Sc.
