Expenditure Breakdown

Introduction:

The following report pertains to geological mapping carried out by the author and an assistant in June 1983 on the Detour-Lower Detour Lake claim block. Previous geological mapping on the property in July and August 1980 by the author and D. J. Robinson with two assistants had examined all outcrops on the property with considerable emphasis on stripping moss. The present programme was carried out in order to tie in all outcrop, diamond drill, and overburden drill data to picket line grids.

Location and Access:

The Detour-Lower Detour Lake property consists of 278 contiguous mining claims (Table 1) which constitute approximately 4448 hectares. The property is located 130 km NNE of Cochrane, Ontario and 5 km south of the Detour Lake gold mine. Access is available all year by fixed wing aircraft or by all terrain vehicles from the mine site along the winter road.

P.709761 - 709764 (4)	March 25, 1984

Linecutting:

A picket line grid of approximately 444 km was cut over the Detour-Lower Detour Lake claims in order to facilitate geological mapping and geophysical surveys. Selected portions were cut in January-February of 1982 by Ingamar Exploration of Connaught, Ontario and the remainder cut in January-March 1983, by Jean Alix and Co. of Val d'Or, Quebec. An east-west base line ten kilometres long was established with north-south cross lines every 100 m. On the south-west corner of the property the strike of the rocks necessitated a grid with a base line oriented northeast-southwest. Numbered pickets were placed every 25 m along all lines. Tie lines were established along the northern boundary and along the Taylor survey line.

Summary of Exploration:

Previous to the claim block being staked by Westmin Resources portions of the property had been staked by a number of companies namely;

Penarroya 1971-1972 (File 2.823)

Penarroya conducted ground VHEM and fluxgate magnetometer surveys on five geophysical anomalies within the present claim block. The Penarroya anomalies correspond to the Westmin anomalies as follows:

Penarroya	Westmin
H east	INPUT #10
H west	Formation conductor
#21	INPUT 7
J	INPUT 3
K	INPUT 2A
L	INPUT 2B

One of these conductors was diamond drill tested (Anomaly L) although no assessment record or drill core is available.

Inco 1971 (Lower Detour Lake DDH Report 15)

One hole of 115 m tested the formation conductor near the Taylor Base Line intersecting graphitic metasediments and mafic tuff.

Amoco 1974-1976 (File 2.2139

Hopper Lake DDH Report 25-1)

Ground geophysical surveys (EM and magnetometer) evaluated the claims and one drill hole of 132 m tested the formation conductor near the Taylor Base Line west of the Inco hole. This also intersected graphitic metasediments and mafic tuff.

Noranda 1974-76 (Files 2.1833, 2.2137, and 2.2157)

File 2.2157 reports on the electromagnetic and magnetic surveys on what is now the east end of the Westmin claims north of the Taylor Base Line. Files 2.1833 and 2.2137 report on the geophysical surveys over what is now the northwest corner of the Westmin property. In both cases geophysical conductors were

detected, that in general correspond to conductors located by Westmin geophysical surveys. No follow up diamond drilling was reported by Noranda.

Westmin 1980

An airborne Mark VI INPUT survey conducted by Questor on behalf of Westmin detected ten discrete conductors on the property as well as a large formation conductor that is essentially coincident with the Taylor Base Line.

Westmin 1981

Westmin conducted an overburden reverse circulation drill programme with 60 holes being drilled on this property.

Westmin 1982

Nine diamond drill holes (2071 m) tested Max-Min II (HLEM) conductors and thirteen reverse circulation drill holes were completed to further define anomalous values reported from the 1981 work.

Westmin 1983

The Max-Min II HLEM and magnetometer surveys were completed over the entire claim block and a further eight holes were drilled (1228 m) on this property.

Geology

Pleistocene Geology

The Detour-Lower Detour Lake claim block is covered by extensive areas of muskeg with a few small ridges down ice from the outcrops or bedrock highs. These ridges or "crag and tail" structures are prominent on the airphotos and have a consistent strike of 160° that is parallel to the glacial striae. They are composed of well sorted calcareous sand that is in part derived from the James Bay Lowlands during one of the late Cochrane re-advances. The material underlying the muskeg is a poorly sorted calcareous sand and gravel with a high clay content that makes this material impermeable to water thus resulting in the muskeg bog. The Cochrane till averages 10 - 20 m in thickness. Below the Cochrane till is the Matheson till that is derived from the New Quebec ice advance from the northwest. This till has a sandy to silty matrix with only 2% clay and coarse gravel to boulder sized clasts of gneiss, metavolcanic, and metasedimentary rocks with a minor Paleozoic clast content. The average depth to bedrock over the entire property is approximately 30 metres, although the deepest overburden encountered to date is 60 m and there is generally deeper overburden on the north half of the property.

Archean Geology

Limited outcrop exposure and a general lack of reliable geopetal structures prevent the presentation of a true stratigraphic column with measured thicknesses and relative age relationships. Instead the rock types will be described in the

order that they appear in the legend although no age relations are specifically implied.

Ultramafic rocks

One outcrop of ultramafic rock, a serpentinized ultramafic rock, was mapped west of the winter road and north of the Taylor survey line 35E. The weathered surface is orange-brown in colour with a rough surface resulting from the positive weathering of magnetite crystals. A well developed granular texture is defined by white euhedral crystals (<1mm) in the brown-orange matrix.

The fresh surface is a soft, very fine-grained, blue-green serpentine and magnetite that is slightly talcose with thin veins of magnesite (<1 mm). There are no textures diagnostic of either an intrusive or extrusive origin for this unit. The high magnetite content of this rock gives it a characteristic expression on the magnetic map indicating an approximate thickness of 50 ~ 100 metres and a strike length of five kilometres. This suggests that this unit is either an extrusive ultramafic flow or a sill.

Ultramafic rocks south of the Taylor Base Line have been intersected by drilling in holes D-82-2, 3, 4 and D-83-12 along a strike length of 2.7 km and across an apparent stratigraphic interval of 500 metres. They are best described as a talc chlorite, biotite, carbonate rock depending on the relative proportion of these minerals. The rock is fine grained grey-white to blue-grey to green-brown with a well developed foliation. Magnetite content is extremely variable. No specific volcanic or intrusive textures have been recognized to date.

Mafic Volcanic Rocks

Mafic volcanic rocks form the major rock type on the southern half of the property. They occur as a thick sequence of mafic volcanic flows and tuffs with minor felsic and intermediate members. The rocks of this formation are typical lower amphibolite-greenschist facies volcanic rocks, that is they are light to dark green, soft, extremely fine-grained and generally exhibit volcanic textures, such as pillows, vesicularity, amygdales, and tuffaceous bedding. On the magnetic map this formation is characterized by relatively high magnetic intensity with numerous elliptical zones of greater magnetic intensity, some of which are sub-volcanic gabbro and others are mafic volcanic rocks.

On the southern edge of the property is a sequence (~500 m) of mafic volcanic flows and tuffs with minor inter-flow sedimentary rocks that extend in an arcuate belt from the southwest corner of the Detour claim block across the north end of Detour Lake and southeast to the Detour River. These rocks have been subjected to regional metamorphism of lower to middle amphibolite facies with later contact metamorphism in proximity to the Detour Lake granodiorite-diorite stock. The mineralogy is simple consisting of 10 - 80% pyralspite (Mg, Fe, Mn) garnet in a very fine grained hornblende matrix with minor quartz and no feldspar. Within the contact aureole of the Detour Lake stock Ca-rich almandine garnet of a second composition co-exists with hedenbergite (Barnett, 1980). In mafic flows and pillows the garnets are most numerous on flow contacts and pillow rims. Garnets occur throughout mafic tuffs, often associated with minor

magnetite and/or pyrrhotite and may be so numerous that they have coalesced giving the rock an appearance similar to a breccia or felsic fragmental rock. Within interflow sedimentary rocks fine-grained garnets are present as massive beds or are associated with sugary textured quartz (meta-chert).

Meta-Sedimentary Rocks

a) Turbiditic wackes

These rocks are not present in outcrop on the property, although they were intersected in drill core in hole D-82-9. Where they are exposed in outcrop north of the property and in Quebec they have a light brown soft weathered surface with a well defined bedding that is both very thin bedded and thick bedded in a regular sequence. Quartz veins are prominent parallel to the foliation where the foliation is not parallel to bedding. The fresh surface is light grey, soft, slightly carbonated with a grain size that varies from clay and silt size to sand size particles in scour channels. With the exception of graded beds, sedimentary structures are poorly exposed although cross-beds, flame structures, and soft sediment deformation structures are present on a wave washed outcrop on the Turgeon River in Quebec. The stratigraphic thickness of this unit, as interpreted from the aeromagnetic data, is several thousand metres although the trendless magnetic features make it impossible to detect any possible repetition by folding.

b) Volcanic Conglomerate

The volcanic conglomerate or laharic breccia unit is a thin unit (< 200 m thick) that is traceable across the entire claim block. It is polymictic consisting entirely of volcanic clasts (felsic, mafic, porphyritic mafic, intermediate rocks with quartz eyes, quartz feldspar porphyry, and massive to semi-massive pyritic clasts). These clasts are predominantly elliptical with the long axis parallel to foliation. Maximum clast size is 50 cm x 10-20 cm. The matrix of this unit is a dark green, soft chlorite-sericite rock with a well developed foliation.

c) Graphitic Metasedimentary Rock

This unit is not exposed in outcrop however it is expressed on the INPUT survey as a five or six channel conductor on every flight line from the Ontario-Quebec border until its termination eleven flight lines from the western end of the claim block. There is generally no magnetic correlation suggesting that this unit is dominantly graphite and pyrite. Where this unit has been intersected in drilling, by Amoco and Inco, both the north and south contacts are mafic volcanic tuff. The unbroken and non-repetitive nature of this horizon suggest that there is no major folding or faulting on the south side of the regional fold.

Intrusive Rocks

Gabbro

Gabbroic rocks have a soft dark green weathered surface and a grey green weathered surface that is medium to coarse grained, equigranular, crystalline, and massive to slightly foliated. Quartz and to a lesser extent epidote veins are common. Constituent minerals include feldspar, actinolitic hornblende, biotite, chlorite, epidote, quartz, and carbonate + magnetite. The gabbro intrusions are variable in size but discrete entities that are believed to be sub-volcanic intrusions and sills. Evidence for this synvolcanic age of emplacement is their similarity of magnetic expression and weathering characteristics to some mafic volcanic rocks, their small discrete nature, and the gabbro on the Detour River east of the winter road is cut by a foliated quartz feldspar porphyry dyke. The aeromagnetic expression of these is variable. Some of them such as the two on the north limb of the regional anticline have an oval magnetic pattern although smaller intrusions are not easily recognized on the magnetic map.

Pyroxenite

Metapyroxenite rocks have a soft dark green knobbly weathered surface with megacrysts 1 - 2 cm in diameter that are altered to actinolitic hornblende. The fresh surface is a massive beige grey to dark green. This unit is distinguished from the gabbro by the absence, or minor amounts, of feldspar on the weathered rind.

Granite

Granitic rocks exposed on Detour Lake have a massive white to pink weathered surface with a very poorly developed foliation. They are medium to coarse-grained, equigranular and consist of quartz, alkali feldspar, plagioclase, biotite and hornblende. There is a marginal phase of gabbro, quartz gabbro and diorite that is exposed along the Detour River. These rocks are also massive, medium to coarse-grained, equigranular and slightly foliated, as well as being slightly foliated. These intrusive rocks are believed to be related to the Kenoran orogeny and unrelated to the gabbro's discussed above. The aeromagnetic expression of these rocks is a trendless pattern that is similar to that of the turbidite wackes.

Diabase

No diabase dykes are exposed on this property although there is one exposed on the Amoco-Campbell Red Lake-Dome property (Johns, 1979) that has a north north-west trend. This has a weak magnetic expression in the turbidite wacke unit and is projected to continue in the eastern part of Lower Detour Lake.

Structural Geology

The Detour-Lower Detour Lake claims are located on the south limb of a large east-west trending fold (Johns, 1979) that may be either a synform or antiform. The south limb appears to be a homoclinal sequence that is vertical to steeply south dipping with no major faulting or folding. Evidence for this is the unbroken and non-repetitive nature of the formation conductor along the Taylor base line, the east-west linear magnetic high north of the Taylor base line that marks the ultramafic sill or flows, and the outcrop expression of the lahar that can be traced across the entire property. The structure on the southern part of the property has been modified by the intrusion of the Detour Lake granite such that the garnetiferous mafic volcanic rocks form an arcuate pattern around the north end of Detour Lake.

Economic Geology

Exploration to date has not defined any zones of economic significance. Diamond drill testing of HLEM targets has intersected either graphite + pyrite + pyrrhotite or pyrite and pyrrhotite.

Certification

I, Christopher J. Rockingham, of 261 Booth Avenue, Toronto, Ontario, M4M 2M7, certify the following:

- 1) I am a Fellow of the Geological Association of Canada.
- 2) I hold a B.Sc., in Chemistry and Biology obtained from the University of Toronto, in 1972 and a M.Sc. in geology obtained from the University of Western Ontario, in 1979.
- 3) I have practised my profession for 9 years working in Canada, Australia and Southern Africa.
- 4) I have supervised the work and interpreted the results mentioned in the foregoing report.
- 5) I have no financial interest in this property.

MINING LANDS SECTION

Dear Sir: Your File: 2.5963 and letter dated January 6, 1984

We are returning the geological maps with the coloured outcrops as requested. As the last page of the report has not been enclosed (as indicated in your letter) we can not oblige your request. I have checked the last page of this report and the last page has been signed and dated.

Thank you, and I hope you will find everything in order.

Yours truly,

WESTMIN RESOURCES LIMITED
