SUMMARY

Mustang Minerals Corp. (Mustang) acquired the River Valley property in early 1999 in order to explore the River Valley gabbro-anorthosite intrusion for economic concentrations of contact-type platinum group metal mineralization. First phase exploration was initiated in early October and geological mapping commenced on October 15, 1999 and was completed by December 6, 1999. During this time a total of approximately 75 line kilometres of grid were systematically mapped (1:5000), sampled, prospected and also covered by a ground magnetic survey. A total of 452 locations were sampled and submitted for assay.

The mapping, sampling and prospecting program confirmed that the historical copper-nickel showings also contain anomalous to highly anomalous concentrations of Au+Pt+Pd (PGM) with a best assay of 2073ppb PGM. It should be noted that four areas with PGM enrichment have been identified, two of which have been recommended for follow up testing: the length of the intrusive contact covered by the grid; and, a zone of PGM enrichment associated with magnetite-bearing leucogabbro to gabbroic anorthosite on the west end of the grid and north of the baseline. A program of IP followed by trenching and stripping over selected anomalies in areas with thin overburden cover is recommended. Diamond drilling should subsequently test the continuity of the best targets at depth.

INTRODUCTION

Mustang Minerals Corp. (Mustang) acquired the River Valley property in early 1999 in order to explore the River Valley gabbro-anorthosite intrusion for economic concentrations of contact-type platinum group metal (Au+Pt+Pd) mineralization. The first phase 1999 exploration program was initiated in early October with linecutting. Between October 15 and December 6, 1999, approximately 75km of 200m grid were systematically mapped at 1:5000, sampled, prospected and also covered by a ground magnetic survey (Patrie, 1999). Analytical results are presented in Appendices 1 and 2, respectively. The South Grid Bedrock Geology map (1:5000 scale), and the Sample Location and PGM Assay Data map (1:5000 scale) are located in Pockets 1 and 2, respectively, at the back of this report.

LOCATION AND ACCESS

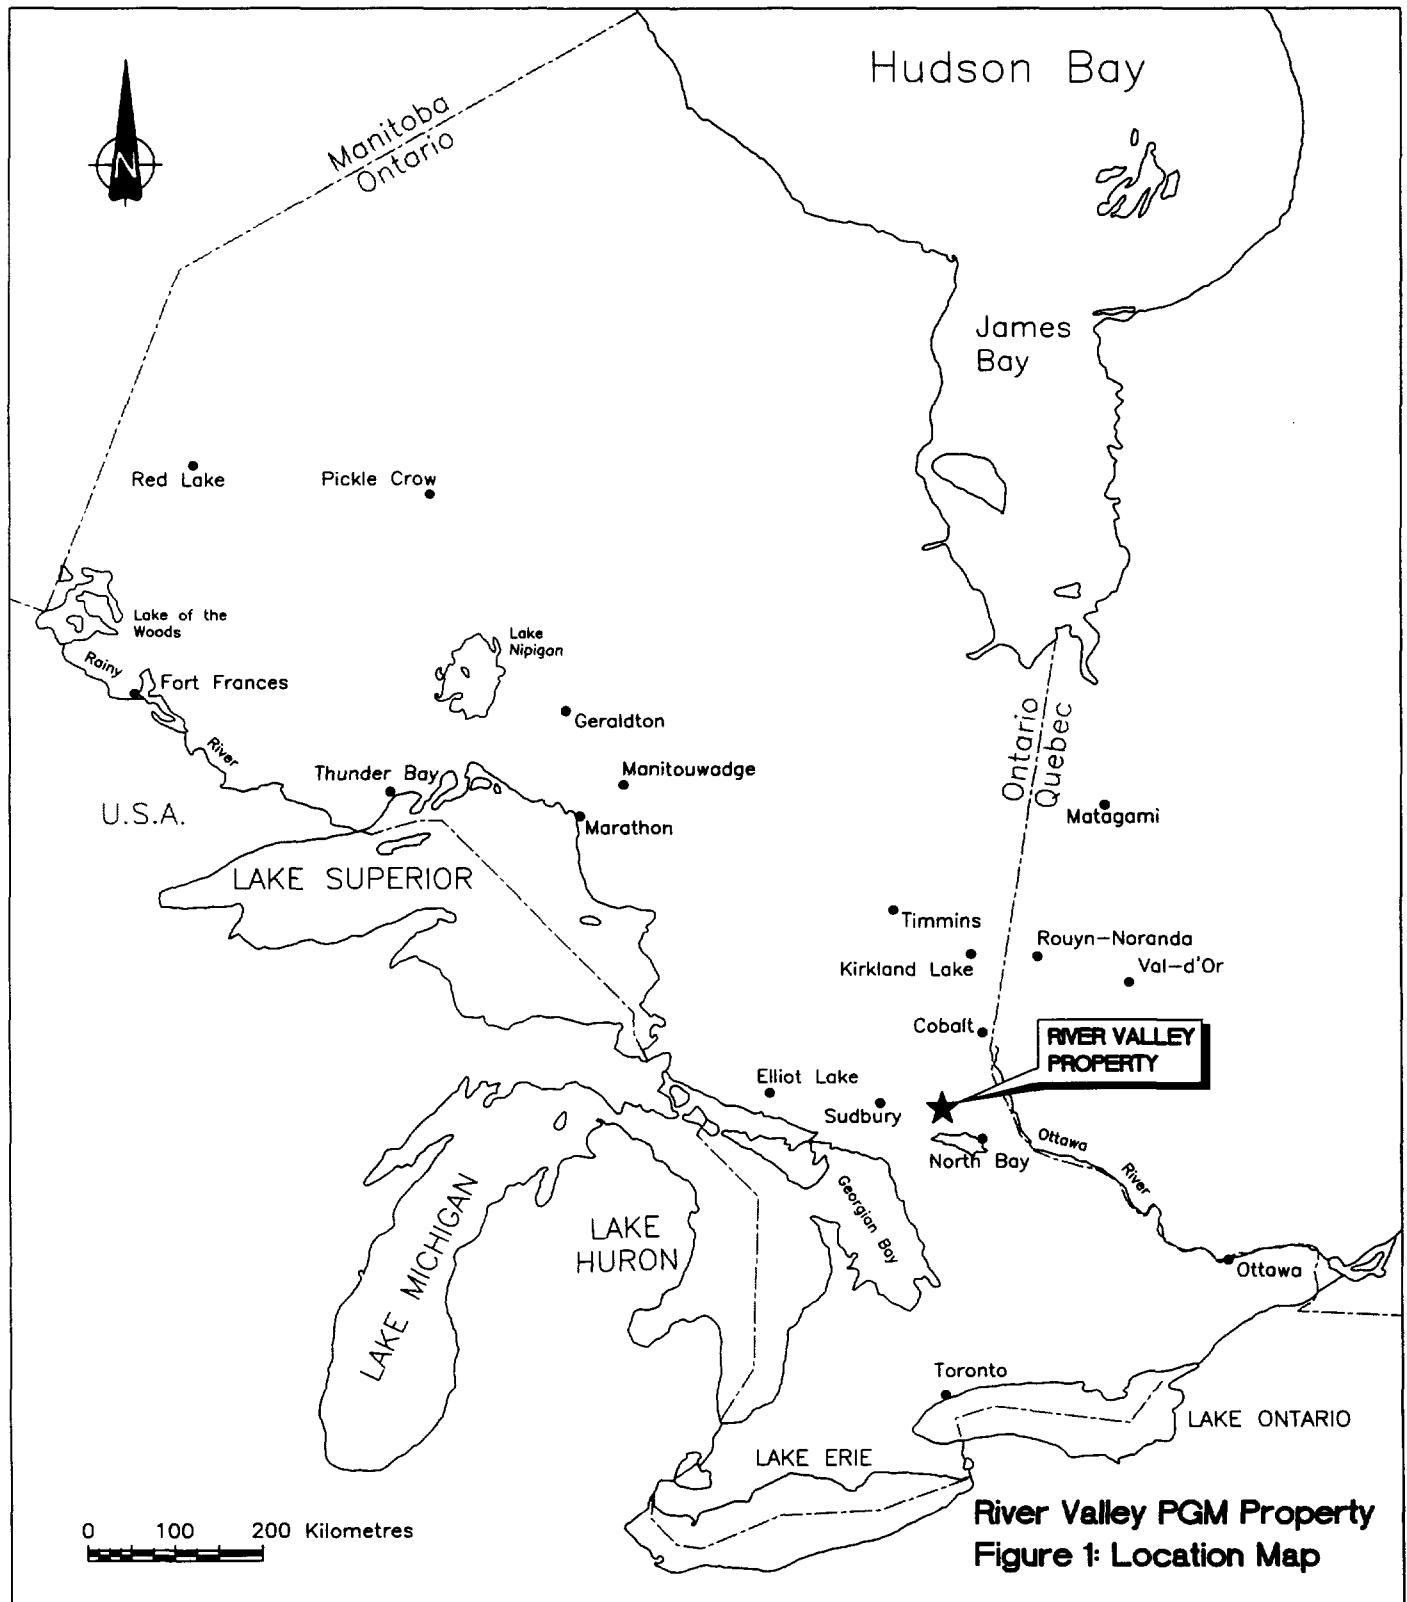

The River Valley property is located approximately 50km east of Sudbury and covers roughly 8200 hectares (see Figure 1). The claims occur within NTS 41I/09 and are centred on latitude 49° 36' N and longitude 80° 17' W (554892mE, 5160746mN, UTM Zone 17, NAD 27) as shown in Figures 1 and 2.

Excellent year round access to the property can be gained from Sudbury by travelling east on Highway 17 to Warren, and then northwards on Highway 539 to the town of River Valley. The Rochon Road, just south where Highway 539 crosses the Sturgeon River, traverses the southern portion of the South Grid. Additionally, several logging and hunting trails provide access to the northern portions of the grid. Supplies and accommodations are available at the town of River Valley (see Figure 2).

TOPOGRAPHY AND VEGETATION

The property is a contrast in terrain types with flat, wet swampy areas to overburden covered areas exhibiting flat to rolling topography, and some outcrop areas exhibiting rugged to extremely rugged, steep-sided ridges and hills (e.g. the "Hay Stack") (see Plate 1). Overall relief is in the order of 110m and ranges from 230m at the banks of the Sturgeon River up to approximately 340m above sea level. The area is relatively well-drained and forested by mature black spruce, pine, birch, poplar, maple and oak. In lower wet areas the cover is typically spruce, cedar, tamarack, labrador tea and sphagnum-covered muskeg.

Overburden is typically composed of glaciofluvial (gravel and sand) and glaciolacustrine (sand, gravelly sand and gravel) deposits (Barnett et al., 1991). Locally, glacial striae on exposed bedrock indicate an approximate north-south ice flow direction. Newman (1996) reports that the overburden covering the western and northern portions of the intrusion is characterized by a relatively thin veneer of till over intermittent bedrock knobs.

River Valley PGM Property
Figure 2: Grid Location Map

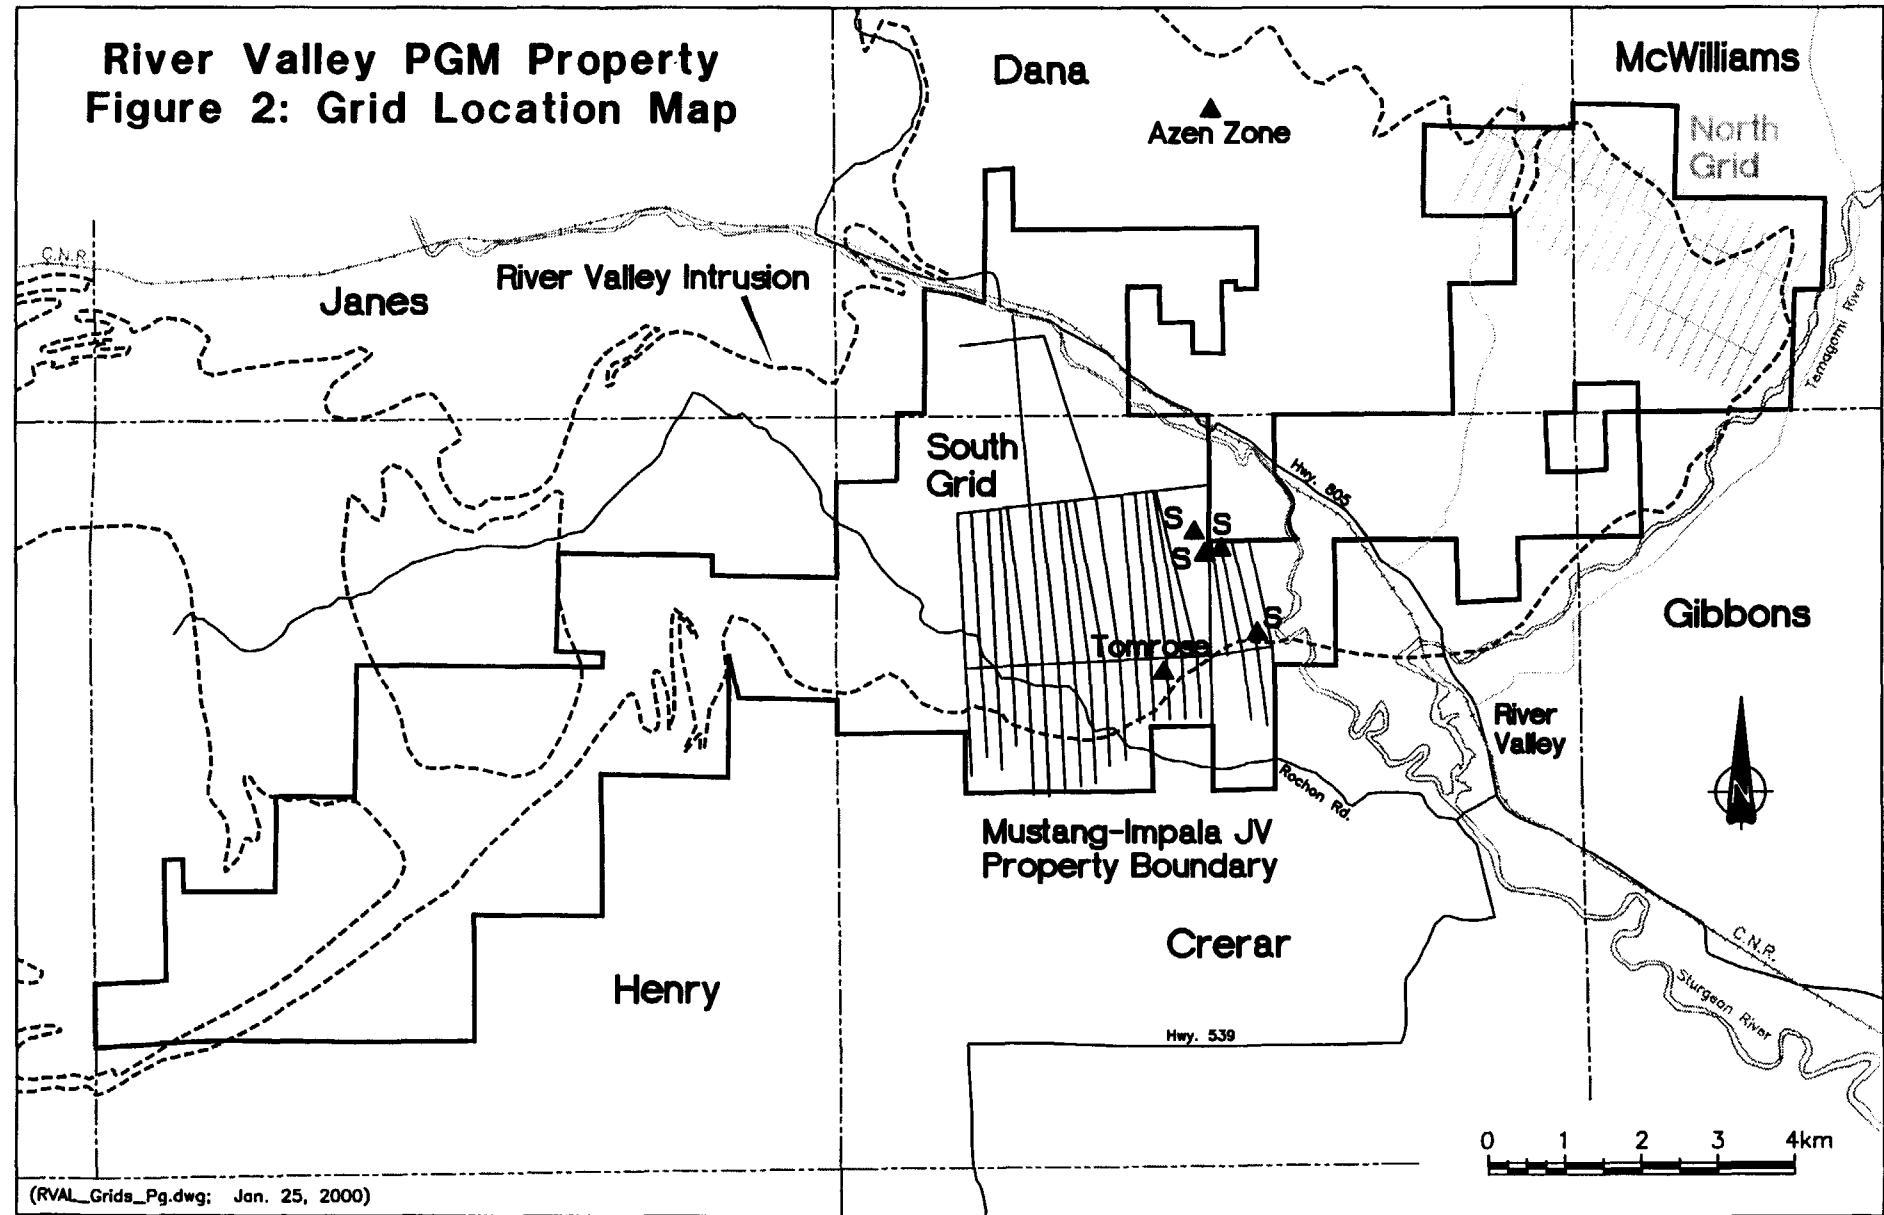

Plate 1: View illustrating terrain variation on the River Valley property, South Grid.

Water suitable for drilling is readily available from rivers, creeks, streams and numerous beaver ponds. It should be noted that the property occurs in a cultural heritage area and special permission is necessary before commencing any exploration programs that result in the disturbance of soil.

PROPERTY

The River Valley PGM property (see Figure 3) consists of 54 contiguous, unpatented mining claims, totalling 511 units covering approximately 8176 hectares. The claims are located in Crerar (G-2903), Dana (G-2094), Gibbons (G-2905), Henry (G-2913) and McWilliams (G-2910) townships, Sudbury Mining Division, Ontario. Mustang acquired the property in early 1999 through staking and several option agreements.

Subsequently, during early August 1999, Mustang signed a letter of intent to jointly explore its River Valley property with Impala Platinum Holdings Limited (Implats), the world's second largest primary producer of platinum group metals. In order to earn a 60% interest in the property, Implats must incur work expenditures totalling C\$6 million over five years, and make cash payments totalling C\$255,000 over four years. A number of the claims are subject to various Net Smelter Returns back to the original vendors which are documented in the underlying agreements. All claims are currently in good standing and are listed in Table 1.

REGIONAL GEOLOGY

The River Valley property is underlain by the early Proterozoic-aged (2475+2/-1 Ma) River Valley Intrusion, a layered gabbro-anorthosite pluton. The intrusion is approximately 30km long and up to 15km wide, and is part of the Huronian Nipissing Magmatic Belt, which includes the East Bull Lake and Shakespeare-Dunlop intrusions which are located in the Southern Province to the west of Sudbury (see Figure 4). The River Valley Intrusion occurs close to the juxtaposition of the Superior, Southern and Grenville provinces. The intrusion is situated in the Grenville province and is cut, but not displaced, by the Grenville Front tectonic zone along the northwest margin. Regionally, the River Valley pluton is associated with a large, positive gravity anomaly that suggests a possible associated denser, more mafic phase at depth.

PROPERTY GEOLOGY

The River Valley area was mapped by Lumbers (1973) during a regional reconnaissance mapping program, which broadly outlined the geology of the River Valley Intrusion, the surrounding host rocks and the location of the Grenville Front (see Figure 5). More recently, Easton and Hrominchuk (1999) and Hrominchuk (1999) have examined and documented the geology, stratigraphy and copper-platinum group element potential of Dana and Crerar townships.

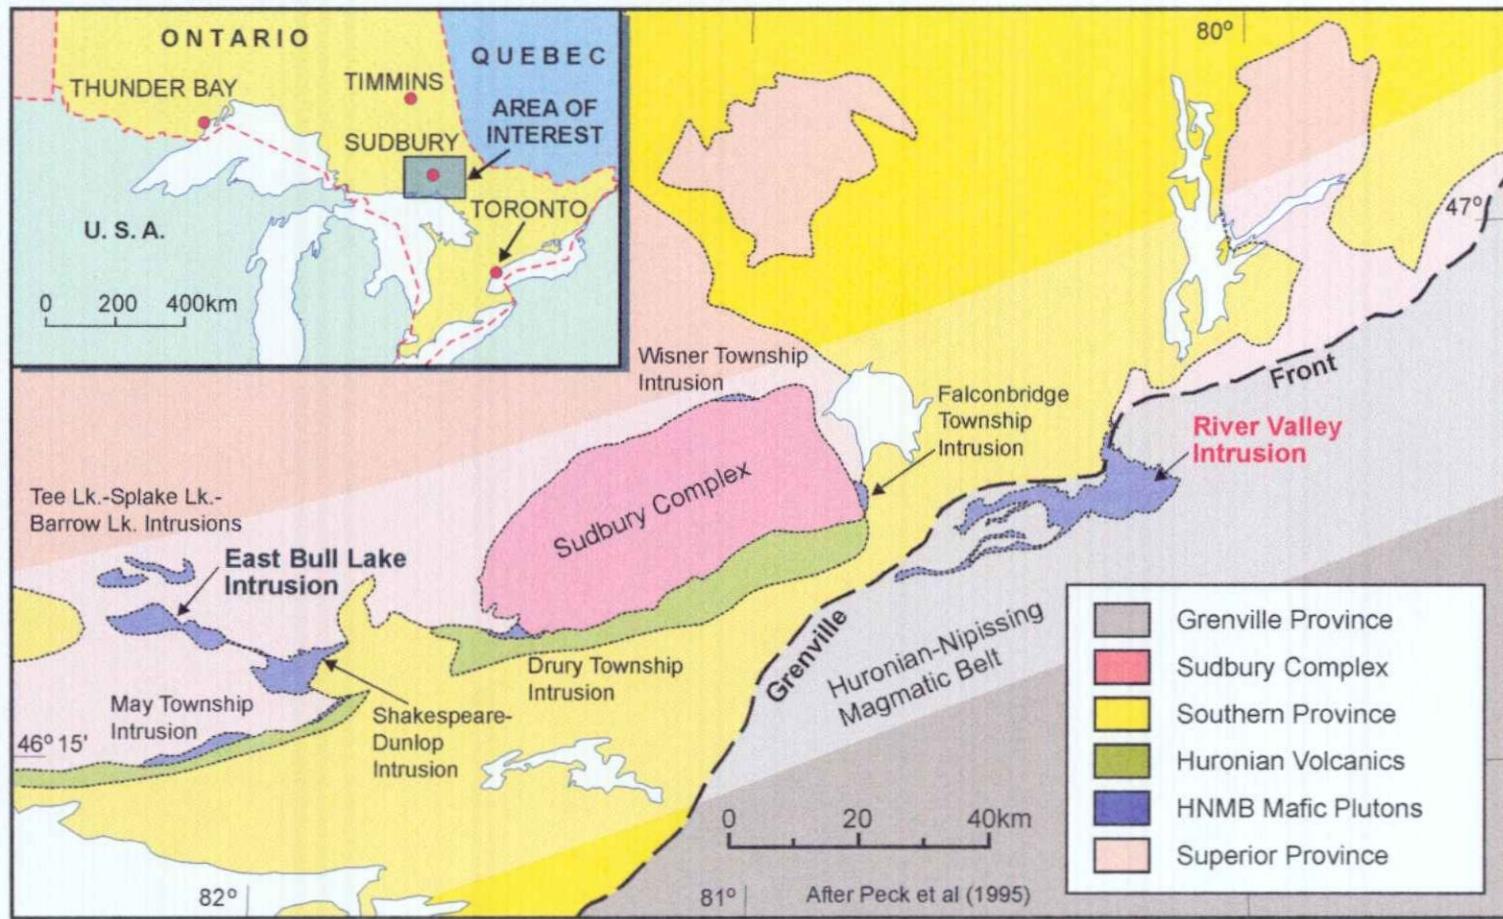

Mustang's River Valley PGM property is underlain by the River Valley gabbro-anorthosite intrusion and high-grade metasedimentary gneisses of the Grenville Province (see Figure 5). Ashwal and Wooden (1989) report that the intrusion is comprised mostly of leuconorite and leucogabbro with lesser anorthosite, mafic and ultramafic phases. More recently however, Easton and Hrominchuk (1999) indicate that the intrusion is dominated (~60% of the surface area) by gabbro, norite, gabbronorite, leucogabbronorite, and leuconorite compositions. True anorthosite forms only 10% of the surface exposures of the intrusion. Minor Cu-Ni-PGM mineralization occurs in the southeast portion of the intrusion (Tomrose Occurrence).

PREVIOUS WORK

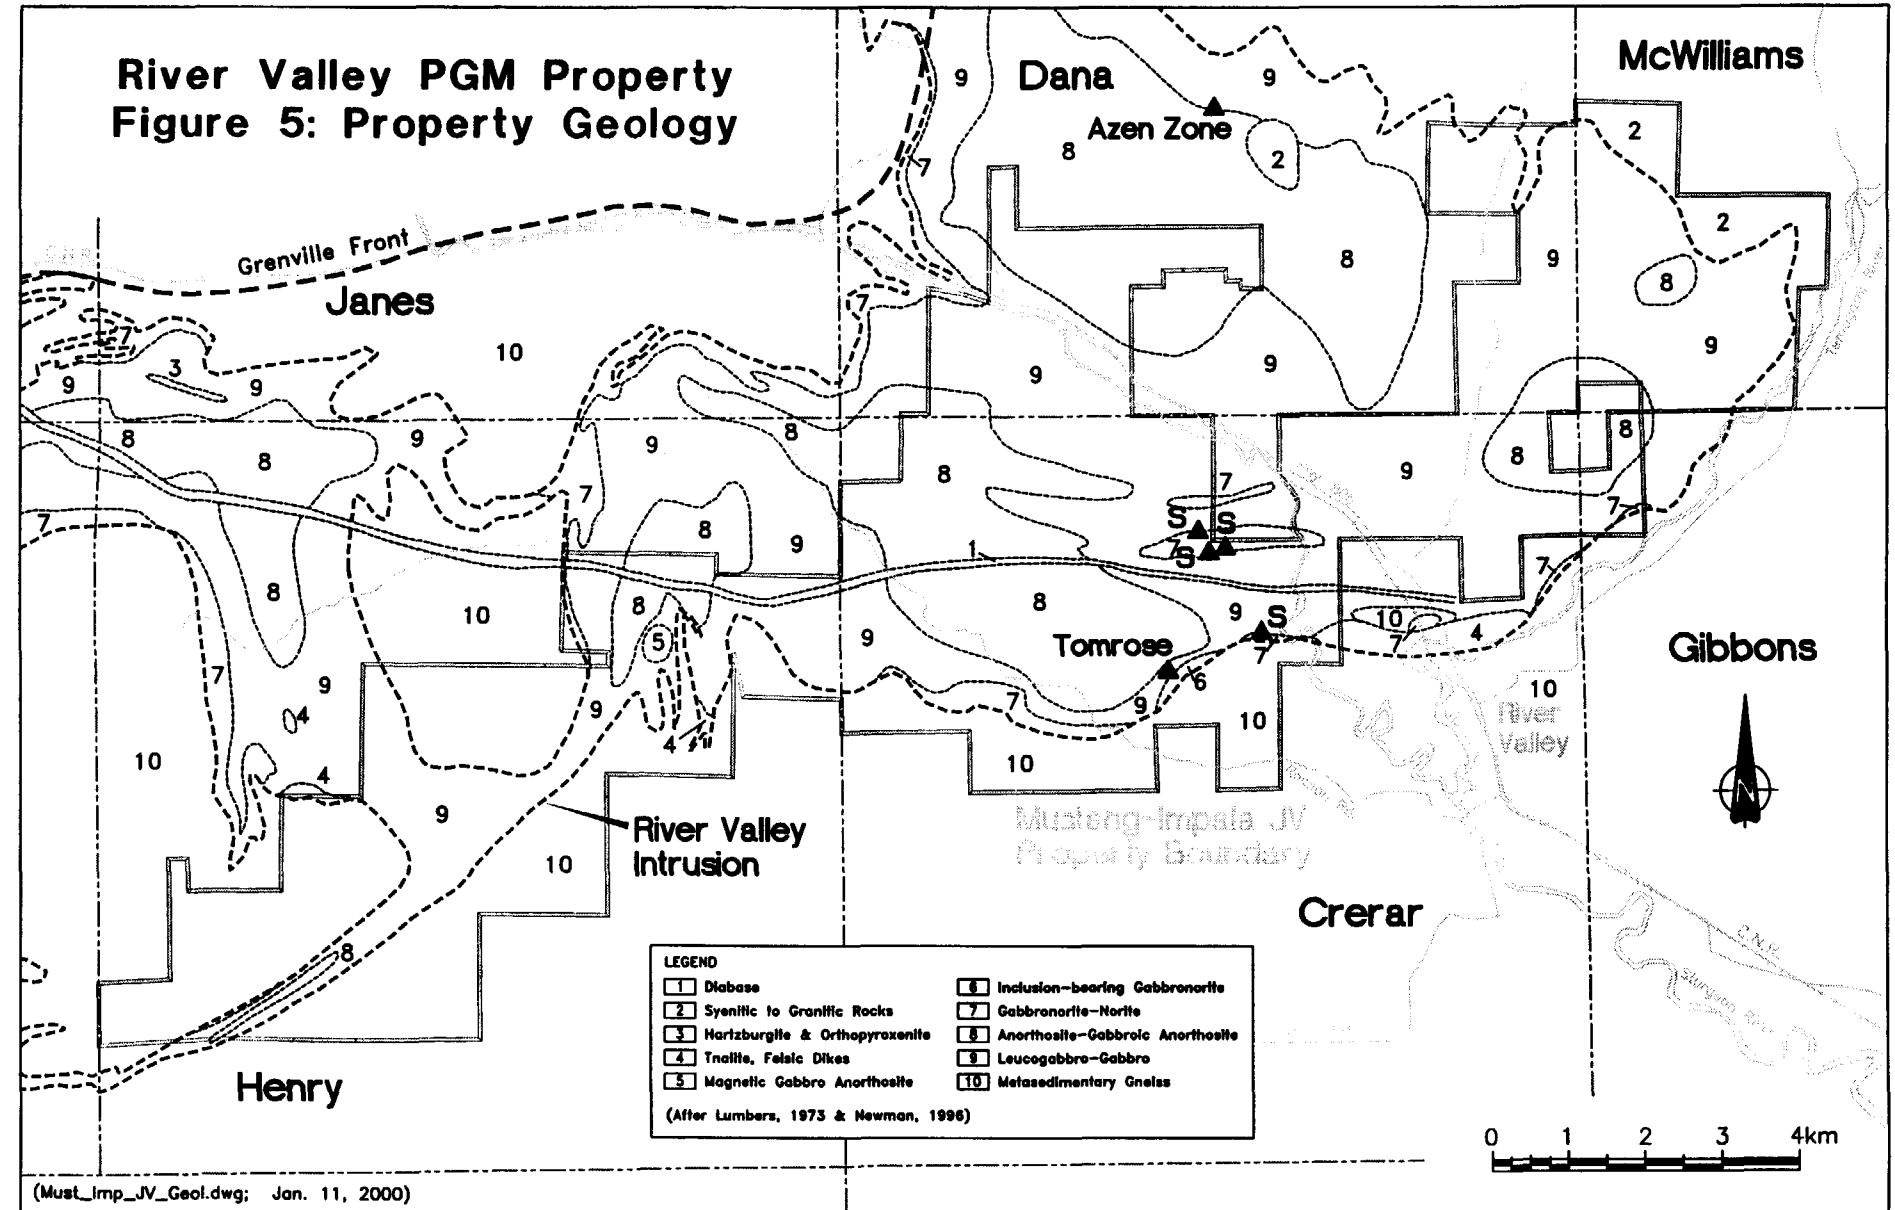

Information on previous exploration activities on the River Valley Intrusion is available from the Ministry of Northern Development and Mines in Sudbury, or through the ERLIS database.

The River Valley Intrusion has been the focus of relatively limited exploration activity over the past 45 years, and the bulk of this work has attempted to locate marginal-type massive copper-nickel sulphide mineralization similar to the Sudbury deposits. However, the intrusion has never been systematically explored for Platinum Group Metals (PGM) associated with disseminated sulphides (e.g. Stillwater and Lac des Iles deposits). Interestingly, it should also be noted that the Sudbury mines have collectively produced in excess of 20 million ounces of PGM as by-product from the nickel-copper ores.

Figure 4: Location of Early Proterozoic Layered Complexes in the Huronian-Nipissing Magmatic Belt, Ontario

River Valley PGM Property
Figure 5: Property Geology

Between 1973 and 1996 much of Dana Township was included in the Temagami Land Caution, and was not available for staking. Additionally, historic building stone quarries are present in better preserved portions of the River Valley Intrusion north of the Sturgeon River in Dana Township. These quarries exploited a black anorthosite that is locally known as "Black Granite". Coarse garnet was also extracted from the gneisses in east-central Dana Township just north of the intrusive contact.

Historically, previous exploration work has focused on the southeastern contact of the intrusion in Crerar Township and is summarized chronologically below:

1956: McIntyre Porcupine Mines, Limited completed two diamond drill holes on the Ferguson claims to test quartz veins with associated semi-massive chalcopyrite-pyrite mineralization. The holes totalled 32.6m (107 feet) on historic claim 90348. The best intersection was reported at 25% Cu and 0.01% Ni over 0.61m (2.0 feet).

1960-1962: Tomrose Prospecting Syndicate completed prospecting, rock trenching, character sampling and 113.7m (373 feet) of pack sack drilling. Additionally, a total of 20 pits and trenches were excavated. The best assays from this work included 25% Cu and 8.9 g/t Au (0.26 opt).

1963-1964: Tomrose Mines Limited completed prospecting and 13 diamond drill holes (1 to 9 and 64-10 to 13, inclusive) totalling 1233.83m (4,408 feet). Although no significant assays were reported the drill logs indicated that several drill holes had intersected significant concentrations of sulphides (pyrite, pyrrhotite and chalcopyrite) associated with blue quartz eyes within the intrusion. The holes were drilled on historic claims 52410 and 51682.

1965: Falconbridge Nickel Mines optioned the Tomrose property and completed ground magnetometer and electromagnetic surveys and six diamond drill holes (CRE-1 to 6, inclusive) totalling 331.01m (1086 feet). No significant assays were reported and Falconbridge subsequently dropped the option.

1965: Tomrose Mines Limited, drilled two holes (NE-1 & 2) for a total of 114.00m (374 feet). No assays were reported.

1966: Tomrose Mines Limited, completed one 134.72m (442 feet) diamond drill hole (T66-1). Minor sporadic pyrrhotite, pyrite and chalcopyrite were reported but no assays were submitted.

1966: Azen Mines Limited, staked 10 claim units to the west of the Tomrose claim group and conducted a ground magnetic survey only. No drilling was reported.

1983-1986: Albert Leblanc drilled three holes (1-83, 1-84 and 1-86) for a total of 104.85m (344 feet) on two claim units in the northwest corner of Henry Township. No assay results are available.

1990: Albert Leblanc drilled three holes (90-1 to 90-3) for a total of 403.56m (1324 feet). Only 14 samples were submitted for assay and up to 338ppb PGM was reported. It also appears that Teck Explorations Limited logged the core from at least one hole

(DDL-0143; 153.01m). Interestingly, the drill log indicated a 34.78m (114.1 feet) sulphide mineralized section with sulphides ranging from trace up to 4% disseminated pyrrhotite, chalcopyrite and pyrite; however, no assay results were reported.

1994: Albert Leblanc conducted power stripping on three areas under an OPAP Grant. The claims were subsequently optioned by WMC International and formed part of a larger land package that was being assembled at that time.

1994-1996: WMC International Limited, staked and optioned a total of 1541 units covering a large portion of the River Valley Intrusion in an attempt to explore for marginal type Ni-Cu-PGM mineralization. An integrated program of airborne magnetic and electromagnetic geophysical (DIGHEM) surveys, soil and till geochemical surveys, and reconnaissance mapping and sampling was conducted. Several areas of interest were identified within the intrusion; however, no follow up work was performed. The report also confirmed the high PGM potential of the intrusion.

1998-1999: R. Bailey, L. Luhta and R. Orchard discovered two significant PGM prospects (Dana North and Azen Creek zones) associated with the northern contact of the River Valley Intrusion in Dana Township. Interestingly, these claims are situated within the area that was previously included in the Temagami Land Caution. This property was optioned by Pacific Northwest Capital Corporation (PFN) in 1998, and is currently being explored under an option-joint venture agreement (August, 1999) between PFN and Anglo American Platinum Corporation Limited (Amplats). Preliminary results from the 1999 outcrop stripping and detailed sampling programs in the Dana Lake Area have indicated five mineralized zones, which extend over a distance of 780m and are anomalous to highly anomalous (0.25 to 16.0g/t PGM). An average assay value of 376 samples that were collected from the mineralized zones average 2.4g/t PGM, 0.16% Cu and 0.04% Ni. Rhodium averages 0.05g/t, with individual assays ranging up to 0.3g/t.

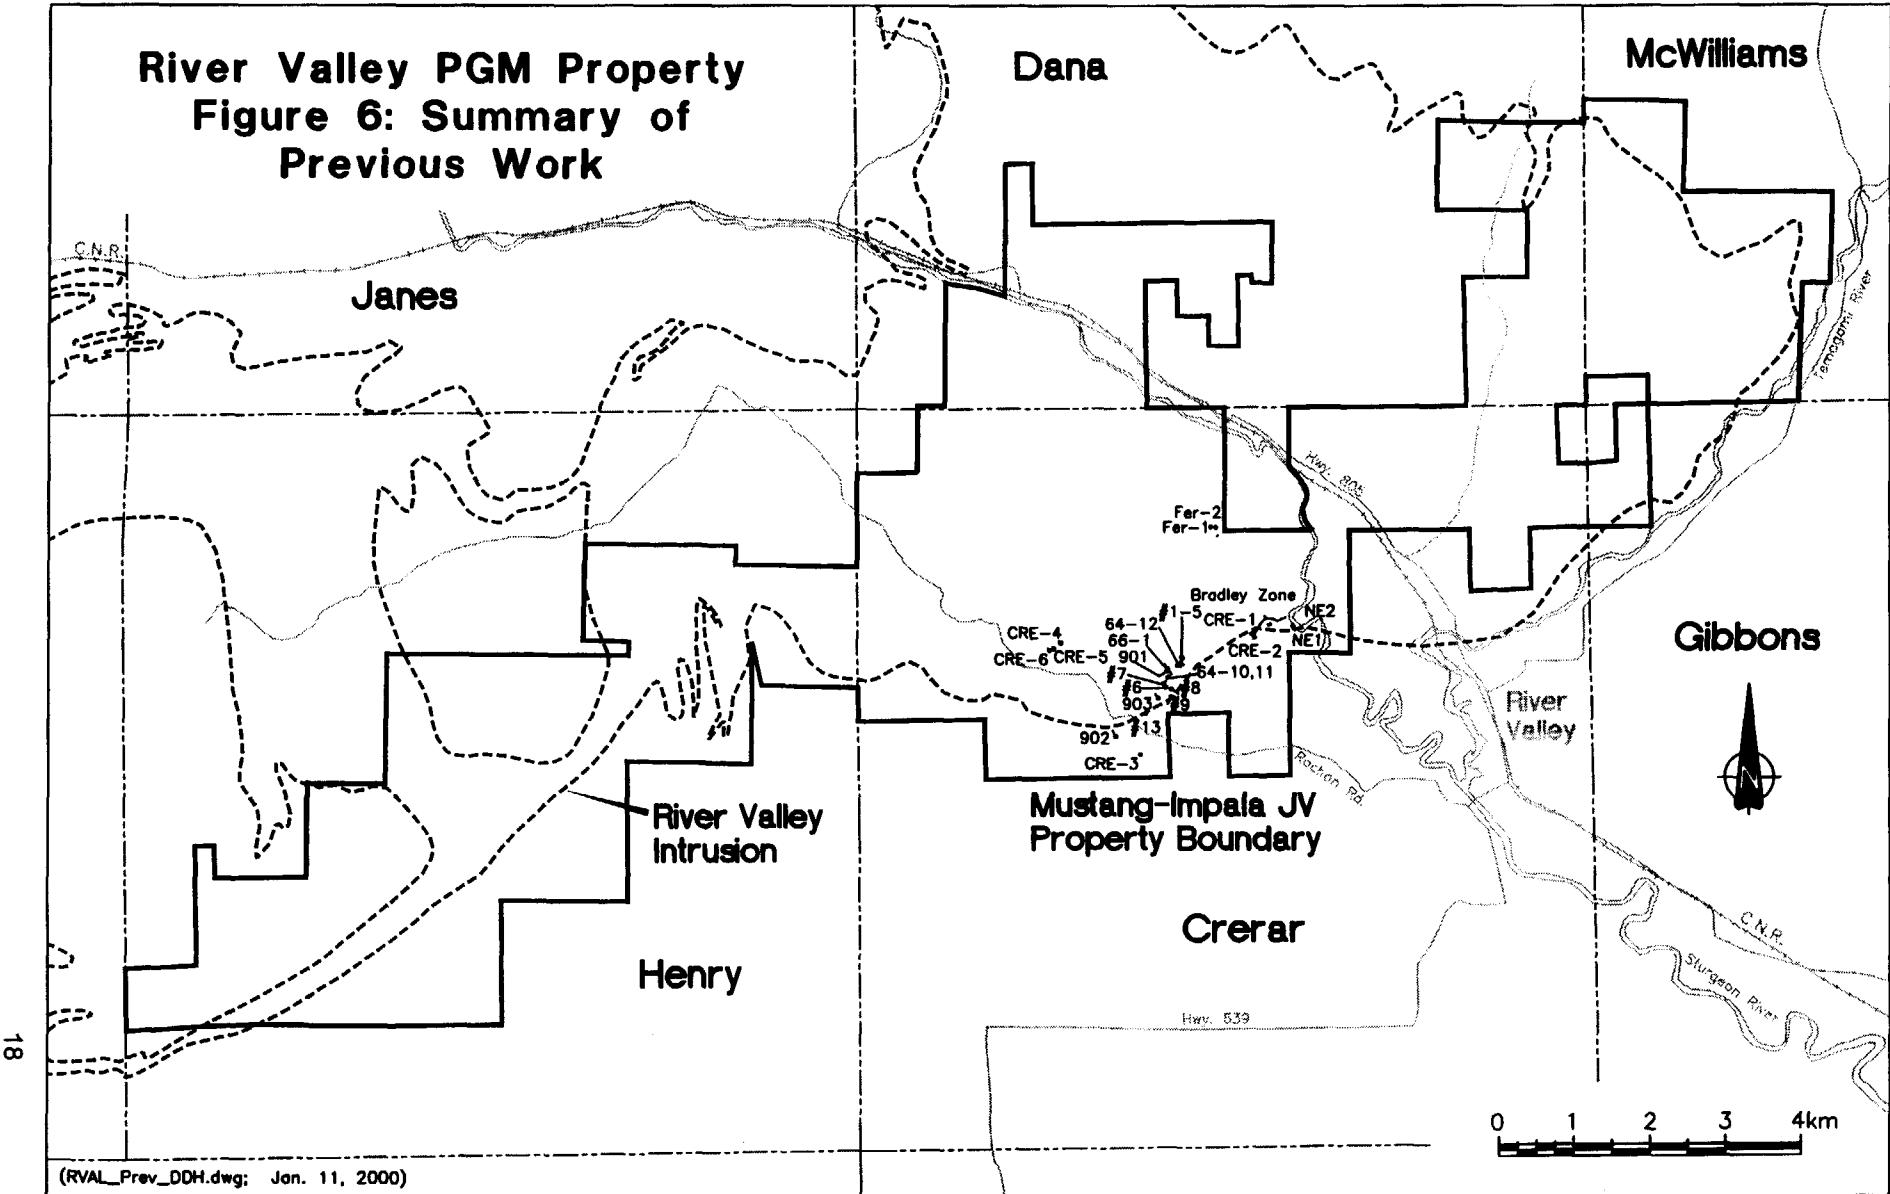

1999: Mustang Minerals Corp. performed a geological prospecting survey on the Tomrose Zone (Albert Leblanc claims) in Crerar Township and several claims in Dana and McWilliams townships. Mustang verified the that the Cu-Ni showings are enriched with platinum group metals with assays up to 0.69g/t PGM.

For convenience, the previous exploration activities are also summarized in Figure 6.

GEOLOGICAL MAPPING PROGRAM

Geological mapping commenced on Mustang's River Valley Property on October 15, 1999, and was completed by December 6, 1999. During this time a total of 75 line kilometres of 200m grid were systematically mapped at 1:5000, sampled, prospected and also covered by a ground magnetic survey (Patrie, 1999). A total of 452 locations were sampled (one sample for assay and one representative hand sample from each location) giving an average sample density of approximately one sample every 165m. The current magnetic declination for the area (11° west) was obtained from the Natural Resources Canada, Geomagnetics Laboratory in Ottawa.

River Valley PGM Property
Figure 6: Summary of
Previous Work

Geological mapping was conducted by T. Keast and P. Wood, and both were assisted by G. Wright. It should be noted that as the mapping program commenced so late in the field season it was decided that traverses would be restricted to outcrop exposures that were close to the grid lines. This would ensure that the task was completed before the outcrops were covered with snow. However, several of the sulphide occurrences were not mapped in detail due to snow cover.

Daily travel to the southern portion of the grid was via the Rochon Road that transects the grid from lines 0E to 20E (see Figure 2). The northern portion of the grid is more easily accessed by crossing the Sturgeon River by foot bridge to the north of the town of River Valley, then by ATV trails which extend to the south and west from the northeast corner of the grid.

Rock Units

Mapping was carried out using the WMC geological legend (Newman, 1996) as listed below:

UNIT	ROCK TYPE
11	Late Mafic Dikes
10	Granite
9	Diorite
8	Anorthosite
7	Gabbroic-Anorthosite
6	Leucogabbro, Anorthositic-Gabbro
5	Gabbro
4	Gabbronorite
3	Norite
2	Pyroxenite
1	Metasedimentary Gneiss

Anorthosite was identified on the basis of <5% mafic component. The anorthosite is typically medium- to coarse-grained and composed of plagioclase with minor (<5%), interstitial black amphibole after clinopyroxene. Other accessory minerals included biotite and garnet. Minor zones of black anorthosite were also observed with up to 7% magnetite.

Gabbroic Anorthosite contains between 5% and 15% mafic minerals. These rocks are typically medium- to coarse-grained and composed of plagioclase laths with interstitial black amphibole after clinopyroxene. Textures vary from massive to gneissic.

Leucogabbro, or anorthositic gabbro, is characterized as having between 15 and 40% mafic minerals. The rock is composed of cumulate, medium-grained plagioclase with intercumulate black amphibole after clinopyroxene (see Plate 2). Texturally this unit varies from massive to gneissic. Gneissic leucogabbro was common on the northern portion of the grid and consists of alternating plagioclase bands and amphibole-

garnet-biotite bands (see Plate 3). The leucogabbro unit is the most dominant rock type on the south grid.

Gabbro is defined as having greater than 40% mafic component, with less than 10% of the mafic component being cumulate. The gabbros observed on the property typically consist of fine- to medium-grained cumulate plagioclase in a dark green amphibole-chlorite matrix (see Plate 4). The gabbros generally occur along the margins of the intrusion and as an east-west trending unit across the north of the grid.

Gabbronorite is defined when good cumulate mafic mineral textures are observed. The rock is composed of greater than 40% mafic cumulates with subhedral plagioclase and minor interstitial magnetite.

Norite is defined when cumulate orthopyroxene can be identified.

A **Late Mafic Dike** was observed crosscutting the intrusion on a single outcrop area on line 28E. The dike is magnetite-rich, relatively unaltered, unmetamorphosed and exhibits a good chilled contact. The dikes are easily identified with the magnetic survey as approximately east-west (270° - 290°) trending lineaments that exhibit minor north-south offsets.

Metasedimentary Gneiss was observed along the southern contact of the intrusion in the South Grid area. These rocks are paragneiss and were derived from recrystallized, quartz-feldspathic sediments. These gneissic rocks are easily distinguished from the gneissic intrusive rocks.

Well-preserved, primary, igneous layering was commonly observed in outcrop on the southwest corner of the grid (lines 4E, 6E and 8E south of the baseline). Layering is oriented at 210 to 230 and appears to have a steep dip to the northwest (see Plates 5 and 6).

Analyses

The samples were shipped via courier to XRAL Laboratories, Rouyn-Noranda, Quebec, for analyses. All samples were assayed for Au, Pt, Pd, Cu and Ni. All precious metal concentrations were determined using fire assay (30g charge) followed by a direct coupled plasma/mass spectrometer (DCP) finish. The detection limits for a one assay ton (30g) sample are 1ppb for Au and Pd, and 10ppb for Pt. Base metal concentrations were determined by atomic absorption spectrometry after 0.25 to 0.3g of the pulp was subjected to an nitric aqua regia digestion. Sixteen samples were also submitted for whole rock analyses (major element oxides, LOI and several other trace elements) using x-ray fluorescence spectrometry (XRF) on a fused disc prepared from a 2g sample. The detection limits for all of the major oxides are 0.01% except for TiO_2 at 0.001%.

All of the samples that contain anomalous to highly anomalous PGM will also be submitted for Rh (rhodium) assays. Additionally, a selected number of samples of the reject material remaining from the samples that were processed at XRAL will be submitted to another laboratory for check analyses.

Plate 2: Detail of massive, coarse-grained leucogabbro. Outcrop is east of L6E/~4S (Arrow on scale points to north).

Plate 3: Detail of gneissic leucogabbro with garnet-rich band to left of pencil. Outcrop is located between L36E and L38E just south of TL14+75N (Pencil points to north).

Plate 4: Close up of medium-grained gabbro with small cumulate plagioclase phenocrysts in a dark green amphibole-chlorite matrix. Outcrop is located at L6E/~2+50S (Arrow on scale points to north).

Plate 5: Small outcrop with primary igneous layering - leucogabbro with gabbroic layers. Mineral grading (top?) appears to occur to the west. Outcrop is located on the north side of Rochon Road at ~7E/1+70S (Arrow on scale points to north).

Additionally, six representative samples of mineralized and unmineralized rock were submitted to Quantec Consulting Inc. for physical property determinations (magnetic susceptibility, specific gravity, resistivity and IP chargeability). Two mineralized samples collected from the PFN property (Dana South Zones and Trench Zones) were also included for comparison.

Results of Geological Mapping Program

A program of geological mapping, sampling and prospecting was initiated over the South Grid to locate and test previous Cu-Ni occurrences for PGM enrichment, and explore the River Valley intrusion contact for additional contact-style PGM mineralization. The assay and whole rock results are summarized in Appendix 1, and assay certificates are given in Appendix 2. Included in these results are the major element oxides, LOI and several other trace elements. The physical property results are included in Appendix 3. The South Grid Bedrock Geology Map (1:5000 scale), and the Sample Location and PGM Assay Data map in "bubble plot" format (1:5000 scale) are located in Pockets 1 and 2, respectively, at the back of this report.

The following observations and generalities are made based on the 1999 mapping program:

- The River Valley Intrusion in the vicinity of the South Grid is composed of predominantly leucogabbro to gabbroic anorthosite to gabbro with lesser anorthosite and noritic phases. Metamorphic grade appears to attain at least amphibolite grade. Ongoing geochemistry and petrography will assist in refining rock classification and metamorphic grade determination.
- The south contact of the intrusion appears to be primary (not tectonic) and dips at 50°-80° to the south. It is suggested that this could represent the overturned base of the intrusion.
- The intrusion is generally massive and relatively undeformed in the vicinity of the contact. The rocks show variable degrees of recrystallization and primary clinopyroxene has been commonly replaced by black amphibole. Well preserved primary igneous layering was also commonly observed. Minor deformed, gneissic domains are present; however, the deformation intensity increases to the north (north of ~10+00N) where straight and folded gneisses predominate. Rare undeformed lithons of intrusive rock were occasionally seen in outcrop in this area.
- The best mineralization, in terms of both sulphide and PGM concentrations, occurs adjacent to the intrusive contact in the vicinity of the Tomrose and Bradley occurrences.
- Elevated PGM concentrations are also associated with two other mineral occurrence types:
 - a) Gabbroic anorthosite-leucogabbro rocks that occur on the west side of the grid and north of the baseline, are enriched in PGM. This mineralization is associated with magnetite (up to 10%), a pronounced magnetic anomaly and only trace quantities of sulphide.

- b) Deformed quartz-chalcopyrite-pyrite veins ± disseminated chalcopyrite in gneissic rocks on the northern portion of the grid.
 The significance of these mineralization types is currently unknown.

Assays

Of the 448 samples (4 samples were not reported) that were assayed, two samples contained greater than 1000ppb PGM (56861 - 2073ppb PGM; Tomrose and 56903 - 1105ppb PGM; occurrence east of Tomrose). Additionally, approximately 10% of the samples contained greater than 100ppb PGM. Interestingly, Easton and Hrominchuk (1999) report that, based on their more regional sampling of mineralized and unmineralized rocks from the area, samples containing between 70 to 140ppb PGM and 70 to 140ppm Cu are anomalous. Samples containing higher concentrations (i.e. greater than 140ppb PGM and 140ppm Cu) are described as highly anomalous. Statistical data for the South Grid samples are summarized below:

Average PGM	55ppb
Standard Deviation	128ppb
Range	0 to 2073ppb
Number	448

It should be noted that the samples show a strong negative skew towards lower PGM concentrations and this will consequently result in a relatively large standard deviation.

Platinum/palladium (Pt/Pd) ratios show considerable variation for the South Grid sample population. Ratios range from 0.1 up to 31, but generally fall around 1.0 to 2.0. In highly anomalous samples the ratios are also close to 1.0. The significance of this observation is currently unclear, but is likely related to the processes that resulted in the concentration of PGM in the well-mineralized zones. Another interesting point to note is that highly anomalous copper values do not necessarily correspond with highly anomalous PGM concentrations, and vice versa. This suggests that systematic sampling of rock units may be a safer strategy, rather than simply focusing on rocks with rust-stains or visible sulphides.

Lithogeochemistry

Sixteen representative samples of the River Valley Intrusion in the South Grid area were selected for whole rock and trace element analyses by XRF. These results are presented in Appendix 1. Plots derived by Irvine and Baragar (1971: Alkalies-Silica) and Jensen (1976: Jensen Cation) are used to characterize the intrusive rocks of the River Valley property. As the Alkalies-Silica plot (Figure 7) illustrates, all of the intrusive rocks of the River Valley Pluton have a subalkalic affinity. On the Jensen Cation plot (see Figure 8), most of the River Valley intrusive rocks plot in the calc-alkalic field and define a rhyolitic (anorthosite) to komatiitic (gabbro to gabbronorite) trend. Interestingly, the two samples that plotted in the tholeiitic field are a late crosscutting diabase dike (57419) which plots as a high iron tholeiite and a coarse, magnetite-bearing gabbroic anorthosite (56817) which plots as a tholeiitic dacite.

Physical Property Determinations

Representative samples of the River Valley Intrusion were selected for whole rock and trace element analyses by XRF. These results are presented in Appendix 3 indicate that the rocks generally exhibit high electrical resistivity values varying between 2130 ohm.m and 9130 ohm.m. The densities vary between 2870 to 3310 kg/m³ and are probably related to magnetite content. Magnetic susceptibility is highly variable between different samples and also within individual samples. Finally, the chargeabilities range from 2.56 to 42.05 mV/V (total chargeability). It should be noted that high chargeability values correlate directly with high density values, which in turn probably reflect higher concentrations of magnetite and sulphides. Interestingly, the sulphide mineralized Dana South Zone (DSZ) and Trench Zone (T-1) samples (PFN) exhibits a high density, increased chargeability values, but relatively low magnetic susceptibility. In this case the higher chargeability is likely due to the sulphides present in the rock.

CONCLUSIONS AND RECOMMENDATIONS

The results of the 1999 mapping, sampling and prospecting program, designed to test the River Valley Intrusion in the South Grid area for PGM potential, were very encouraging. Up until most recently, the River Valley Intrusion has received very little systematic exploration for Cu-PGM mineralization. Anomalous to highly anomalous PGM concentrations were detected in several areas that should be investigated further. Other interesting and/or significant results include:

1. The South Grid is underlain by predominantly leucogabbro, followed by gabbroic anorthosite, gabbro, and anorthosite, with only minor norite and pyroxenite.
2. The southern contact appears to be primary and relatively undeformed. Good cumulate textures were observed close to the intrusive contact with the adjacent gneisses.
3. Previous exploration work has located several copper-nickel showings that were never tested for PGMs. The current mapping program has verified that these showings also host anomalous to highly anomalous PGM concentrations.
4. Three styles of mineralization were observed: a) Contact-style mineralization with disseminated pyrrhotite, pyrite and chalcopyrite (e.g. Tomrose and Bradley showings); b) Gabbroic Anorthosite-Leucogabbro hosted mineralization on the west side of the grid north of the baseline. This mineralization is associated with magnetite and only trace quantities of sulphide; and (c) Deformed quartz-chalcopyrite-pyrite veins ± disseminated chalcopyrite in gneissic rocks on the northern portion of the grid. The significance of (b) and (c) are currently unknown.

Following are a series of recommendations for the next phase of exploration on the River Valley PGM Property:

1. In light of the results of the 1999 mapping program and the recent exploration results from the PFN property to the north, exploration should be mainly focussed along the primary contacts of the intrusion. The contacts should be covered with an IP survey (~1000m per line; 500m of intrusion to contact and 250m additional coverage to the north and south) in order to delineate sulphide concentrations.
2. Follow-up to the IP should include trenching and stripping over selected anomalies in areas with thin overburden cover.
3. Wherever possible, detailed geologic mapping should also be conducted over the contact zone mineralization (Tomrose, Bradley etc.) in order to document the width and characteristics of the marginal and inclusion-bearing rocks in these areas.
4. Diamond drilling should then test the continuity of the best targets at depth.

Certificate of Qualification

I, Peter C. Wood, of the city of Timmins, Province of Ontario, Canada, do hereby certify that:

1. I am a practising consulting geologist with Geodigital Mapping Systems Inc., with an office at 637 Algonquin Blvd. East, Timmins, Ontario, and a mailing address of P.O. Box 983, Timmins, Ontario, P4N 7H6;
2. I am a graduate of the University of Toronto, Ontario with an Honours Bachelor of Applied Science Degree (1983) in Geological Engineering and Applied Earth Sciences (Exploration Option), and a Master of Science Degree (1987) in Economic Geology;
3. I have been practising my profession as a geologist in Ontario, Quebec, and the Northwest Territories since 1987;
4. The information contained in this report and accompanying maps is based on personal observations and direct supervision of the field work; and,
5. I hold no interest, directly or indirectly in the properties of Mustang Minerals Corp. nor do I expect to receive any interest or considerations from Mustang Minerals Corp. except for regular fees for work completed.

Dated this 15th day of February, 2000, Timmins, Ontario

Peter C. Wood, B.A.Sc., M.Sc.

Quantec Physical Property Data

Samples submitted for physical property measurements:

- | | |
|-------|---|
| DSZ | Dana South Zone, PFN (9898ppb PGM) |
| T-1 | Trench Zone, PFN (1463ppb PGM) |
| 7761 | Tomrose Occurrence (0.3g/t PGM) |
| 56864 | Leucogabbro, med.-grained, no visible sulphides/rust (23ppb PGM) |
| 56875 | Gabbro, med.-grained, no visible sulphides/rust (89ppb PGM) |
| 56913 | Gabbro, med.-grained, 3-5% cpy, po, 1% mt (162ppb PGM) |
| 57467 | Black anorthosite (Dana Twp.), coarse-grained, tr. Sulphide (98ppb PGM) |
| 57468 | Gabbroic anorthosite, medium- to coarse-grained, 2-3% mt. |

Personal information collected on this form is obtained under the authority of subsection 6(1) of the Assessment Work Regulation 8/96. Under section 8 of the Mining Act, the information is a public record. This information will be used to review the assessment work and correspond with mining land holder. Questions about this collection should be directed to the Chief Mining Recorder, Ministry of Northern Development and Mines, 8th Floor, 933 Ramsey Lake Road, Sudbury, Ontario, P3E 6B5.

Calculations of Filing Discounts:

Work filed within two years of performance is claimed at 100% of the above Total Value of Assessment Work. If work is filed after two years and up to five years after performance, it can only be claimed at 50% of the Total Value of Assessment Work. If this situation applies to your claims, use the calculation below:

TOTAL VALUE OF ASSESSMENT WORK $\times 0.50 =$ Total \$ value of work claimed.

NOTE:

Work older than 5 years is not eligible for credit.

The recorded holder may be required to verify expenditures claimed in this statement of costs within 45 days of a request for verification and/or correction/clarification. If verification and/or correction/clarification is not made, the recorder may reject all or part of the assessment work submitted.

Declaration verifying costs:

John Spiegl
 Please print full name) **RECEIVED** I declare, that the amounts shown are as accurate as may reasonably be determined and the costs were incurred while conducting assessment work on the lands indicated on accompanying Declaration of Work Form # *Mastars Mineral - VP*. I am authorized to make this certification.

Dear Sir or Madam:

Submission Number: 2.20091

Status

Subject: Transaction Number(s): W0070.00049 Approval After Notice

We have reviewed your Assessment Work submission with the above noted Transaction Number(s). The attached summary page(s) indicate the results of the review. WE RECOMMEND YOU READ THIS SUMMARY FOR THE DETAILS PERTAINING TO YOUR ASSESSMENT WORK.

If the status for a transaction is a 45 Day Notice, the summary will outline the reasons for the notice, and any steps you can take to remedy deficiencies. The 90-day deemed approval provision, subsection 6(7) of the Assessment Work Regulation, will no longer be in effect for assessment work which has received a 45 Day Notice. Allowable changes to your credit distribution can be made by contacting the Geoscience Assessment Office within this 45 Day period, otherwise assessment credit will be cut back and distributed as outlined in Section #6 of the Declaration of Assessment work form.

Please note any revisions must be submitted in DUPLICATE to the Geoscience Assessment Office, by the response date on the summary.

If you have any questions regarding this correspondence, please contact JIM MCAULEY by e-mail at james.mcauley@ndm.gov.on.ca or by telephone at (705) 670-5880.

Yours sincerely,

A handwritten signature in black ink that reads "Steven B. Beneteau".
