. Introduction

This report describes the specifications and results of a geophysical survey carried out for Imperial Metals Corporation of 800-601 West Hastings, Vancouver, B.C., V6B 5A6 by Terraquest Ltd., 240 Adelaide Street West, Toronto, Canada. The field work was performed between December 15th and 18th, 1988 and the data processing, interpretation and reporting from December 19, 1988 to January 16, 1989.

The purpose of a survey of this type is two-fold. First to prospect directly for anomalously conductive and magnetic areas in the earth's crust which may be caused by, or at least related to, mineral deposits. A second is to use the magnetic and conductivity patterns derived from the survey results to assist in mapping geology, and to indicate the presence of faults, shear zones, folding, alteration zones and other structures potentially favourable to the presence of gold and base-metal concentration. To achieve this purpose the survey area was systematically traversed by an aircraft carrying geophysical instruments along parallel flight lines spaced at even intervals, 100 metres above the terrain surface, and aligned so as to intersect the regional geology in a way to provide the optimum contour patterns of geophysical data.

2. The Property

S

The property is located in the eastern half of Hutton township, in the Sudbury Mining Division of Ontario about 45 kilometres north of the town of Sudbury and one kilometre north of the hamlet of Milnet. The claims lie along the Vermilion River and can be accessed by the C.N.R. Line, Route 806 which passes to the south and west of the property, and several bush roads within the property.

The latitude and longitude are 46 degrees 51 minutes, and 80 degrees 56 minutes respectively, and the N.T.S. reference is 411/15.

The claim numbers are shown in figure 2 and listed below:

985559-985585 (27) Total of 27 claims

3. Geology

The oldest rocks within the survey area are Archean in age in the southwestern corner. They are comprised of granitic rocks with mafic metavolcanics around the edges. These metavolcanics host iron. copper, gold, silver, nickel and zinc immediately south of the survey block. The past producing open pit iron mine. Moose Mountain, occurs three kilometres to the west. The remaining rocks within the survey area are Proterozoic in age and in order of decreasing age are comprised of quartzite of the Mississagi Formation, conglomerate of the Bruce Formation, limestone of the Espanola Formation, quartzite of the Serpent Formation and argillite of the Gowanda Formation. Four areas of uranium mineralization have been mapped immediately southwest of Bannagan Lake.

The dominant structures in the area trend to the northwest, the Milnet fault coincides with the Vermilion River valley. Numerous cross faults trend to the northeast and a few to the north-northeast and east-northeast.

Survey Specifications

4.1 Instruments

The survey was carried out using a Cessna 182 aircraft, registration C-FAKK, which carries a magnetometer and a VLF electromagnetic detector.

The magnetometer is a proton precession type based on the Overhauser effect. The Overhauser effect allows for polarization of a proton rich liquid of the sensor by adding a "free radical" to it and irradiating it by RF magnetic field. Strong precession signals are generated with modest RF power. The sensor element is mounted in an extension of the right wing tip. It's specifications are as follows:

| Model: | GSM-9BA |
|---------------------|---|
| Manufacturer: | GEM Systems Inc 105 Scarsdale Road Don Mills, Ontario |
| Resolution: | 0.5 gamma |
| Accuracy: | 0.5 gamma |
| Cycle time: | 0.5 second |
| Range: | 20,000-100,000 gammas in 23 overlapping steps |
| Gradient tolerance: | Up to 5,000 gammas/m |

The VLF-EM unit uses three orthogonal detector coils to measure (a) the total field strength of the time-varying EM field and (b) the phase between the vertical coil and both the "along line" coil (LINE) and the "cross-line" coil (ORTHO). The LINE coil is tuned to a transmitter station (Channel 1) that is ideally positioned at right angles to the flight lines, while the ORTHO coil transmitter (Channel 2) should be in line with the flight lines. It's specifications are:

> Model: TOTEM 2A Manufacturer: Herz Industries, Toronto, Canada

Accuracy: 1%

Reading interval: 0.5 second

The VLF sensor is mounted in the left wing tip extension.

Other instruments are:

- King KRA-10A radar altimeter
- PDAS-1100 data acquisition system with two 3.5" floppy disk drives manufactured by Picodas Group Inc., Richmond Hill, Ontario

- Geocam video camera and recorder for flight path recovery, manufactured by Geotech Ltd., Markham, Ontario.
- PBAS-9000 portable field base station with a 3.5" floppy disk drive and an analog print out manufactured by Picodas Group Inc., Richmond Hill, Ontario, coupled with a GSM-8 proton magnetometer manufactured by Gem Systems Inc., Toronto, Ontario.

4.2 Lines and Data

| Line spacing: | 100 metres |
|---|-------------------------|
| Line direction: | 050 degrees |
| Terrain clearance: | 100 m |
| Average ground speed: | 156 km/hr |
| Data point interval: | |
| Magnetic: | 27 metres |
| VLF-EM: | 27 metres |
| Tie Line interval: | 2 km |
| Channel 1 (LINE): | NAA Cutler, 24.0 kHz |
| Channel 2 (ORTHO): | NSS Annapolis, 21.4 kHz |
| Line km over total survey area including overrun: | 126 line km |
| Line km over claim groups: | |
| Magnetic survey totals: | 54 line km |
| VLF-EM survey totals: | 54 line km |

4.3 Tolerances

Line spacing: Any gaps wider than twice the line spacing and longer than 10 times the line spacing were filled in by a new line.

Terrain clearance: Portions of line which were flown above 125 metres for more than one km were reflown if safety considerations were acceptable.

Diurnal magnetic variation: Less than twenty gammas deviation from a smooth background over a period of two minutes or less as seen on the base station analogue record.

Manoeuvre noise: Approximately +/- 5 gammas.

4.4 Photomosaics

For navigating the aircraft and recovering the flight path, semi-controlled mosaics of aerial photographs were made from existing air photos. Each photograph forming the mosaic was adjusted to conform to the NTS map system before the mosaic was assembled.

5. Data Processing

Flight path recovery was carried out in the field using a video tape viewer to observe the flight path as recorded by the Geocam video camera system. The flight path recovery was completed daily to enable reflights to be selected where needed for the following day.

The magnetic data was levelled in the standard manner by tying survey lines to the tie lines. The IGRF has not been removed. The total field was contoured by computer using a program provided by Dataplotting Services Inc. To do this the final levelled data set is gridded at a grid cell spacing of 1/10th of an inch at map scale.

The vertical magnetic gradient is computed from the total field data using a method of transforming the data set into the frequency domain, applying a transfer function to calculate the gradient, and then transforming back into the spatial domain. The method is described by a number of authors including Grant, 1972 and Spector, 1968. The computer program for this purpose is provided by Paterson, Grant and Watson Ltd. of Toronto.

The VLF data was treated automatically so as to normalize the non conductive background areas to 100 (total field strength) and zero (quadrature). The algorithms to do this were developed by Terraquest and will be provided to anyone interested by application to the company.

All of these dataprocessing calculations and map contouring were carried out by Dataplotting Services Inc. of Toronto.

netic maps; unpublished thesis; University of Toronto.

6. Interpretation

6.1 General Approach

To satisfy the purpose of the survey as stated in the introduction, the interpretation procedure was carried out on both the magnetic and VLF data. On a local scale the magnetic gradient contour patterns were used to outline geological units which have different magnetic intensity and patterns or "signatures". Where possible these are related to existing geology to provide a geological identity to the units. On a regional scale the total field contour patterns were used in the same way.

Faults and shear zones are interpreted mainly from lateral displacements of otherwise linear magnetic anomalies but also from long narrow "lows". The direction of regional faulting in the general area is taken into account when selecting faults. Folding is usually seen as curved regional patterns. Alteration zones can show up as anomalously quiet areas, often adjacent to strong, circular anomalies that represent intrusives. Magnetic anomalies that are caused by iron deposits of ore quality are usually obvious owing to their high amplitude, often in tens of thousands of gammas.

VLF anomalies are categorized according to whether the phase response is normal, reverse, or no phase at all. The significance of the differing phase responses is not completely understood although in general reverse phase indicates either overburden as the source or a conductor with considerable depth extent, or both. Normal phase response is theoretically caused by surface conductors with limited depth extent. In some cases, a change in the orientation of the conductor appears to affect the sense of the phase response.

Areas showing a smooth VLF-EM response somewhat above background (ie. 110 or so) are likely caused by overburden which is thick enough and conductive enough to saturate at these frequencies. In this case no response from bedrock is seen.

The VLF-EM conductor axes have been identified and evaluated according to the Terraquest classification system (Figure 4). This system correlates the nature and orientation of the conductor axes with stratigraphic, structural and topographic feaLures to obtain an association from which one or more origins may be selected. Alternate associations are indicated in parentheses.

6.2 Interpretation

The magnetic and VLF-EM data are shown in contoured format on maps at a scale of 1:10,000 in the back pocket. An interpretation map is also provided. The following notes are intended to supplement these maps.

The total magnetic field has a relief of approximately 1,250 gammas and is dominated by strong responses beyond the survey area to the northeast except for a narrow anomaly that extends along the river valley from the southeast. The vertical gradient format identifies several subtle anomalies that trend variably to the northwest.

The source of the strong anomaly to the northeast occurs along the edge of the survey area and appears to be related to mafic intrusives at depth. The nature and orientation of this anomaly can be observed on the government magnetic map (Map 1512G).

The narrow anomaly that extends northwestwards from Fraser Lake has a relief of approximately 250 gammas. It appears to be an extension of the iron formation located along strike to the south of the survey area. The interpreted width is probably exaggerated due to the overwhelming effect commonly associated with strong susceptibilities. The two short anomalies of similar magnitude which occur along strike to the northwest may also be related to iron formation, possibly at depth.

Most of the smaller, broken up anomalies to the southwest correlate with the amphibolitic, mafic intrusive rocks (Unit 4). The subtle anomaly on the east end of Bannagan Lake trends to the northnortheast and is interpreted to originate from similar intrusives.

The mafic metavolcanics (Unit 1) correlate with moderate strength responses. These are best identified where they occur in contrast with the magnetically quiet Proterozoic sediments. The easternmost edge of the metavolcanic unit is characterized by slightly stronger responses (Unit 1m) which may be related to either iron formation, pyrrhotite or more mafic compositions.

The remaining lithologies correlate with weak magnetic responses and cannot be readily dis-

criminated on the total magnetic field map. This is primarily due to the fact that the strong anomaly to the northeast overwhelms and dominates these subtle responses. For example the Gowganda Formation (Unit 9) correlates with the strongest responses on the map area, but are not interpreted to be the source of the magnetism. Similarly, the Bruce Formation conglomerates (Unit 6) correlate with weak responses to the west of Vermilion River and moderate responses north of Bannagan Lake, the difference being a function of the regional gradient across the property.

The subtle anomalies detected on the vertical gradient map correlate with parts of the Bruce Formation (Unit 6m) and parts of the Serpent Formation (Unit 8m). These may be related to minor concentrations of magnetic minerals such as magnetite or pyrrhotite within the Proterozoic sediments. Note that many of these trends are consistent with the bedding of the mapped lithologies. Alternatively, some of these responses may be related to the underlying mafic metavolcanic rocks (Unit 1).

Further processing of the vertical magnetic gradient using the shadowgraph technique is generally consistent with the overall interpretation. In several instances the shadowgraph has identified very subtle expressions that were not present on the vertical derivative plots. These are parallel to and therefore consistent with the overall lithological trends. Note that the shadowgraph is based on a sun declination of 030 degrees and therefore creates a detection bias in favour of northwest trending bodies.

The structural interpretation is highly subjective due to the fact that: a) many of the anomalies are short and truncated, b) there are numerous assumed faults as shown on the mapped geology, and c) many of the anomalies may be derived from sources at depth beneath the Proterozoic sediments. Supporting evidence has been taken from air photo lineaments both within and beyond the survey area. This structural interpretation is not consistent with most of the assumed faults shown on the geological map. The Milnet Fault is not readily identifiable by magnetic mapping as it is parallel to the magnetic units.

Most of the magnetically interpreted faults trend to the east to east-southeast. It is suspected that these offset the Milnet Fault in at least two places. Minor faults or shear zones trend to the north to north-

| SVMBUI | | |
|------------------|--|---|
| STABOL | CORRELATION | ASSOCIATION: Possible Origins |
| a , A | Coincident with magnetic stratigraphy | Bedrock magnetic horizons:'stratabound mineralog origin or shear zone |
| b, B | Parallel to magnetic stratigraphy | Bedrock non-magnetic horizons: stratabound mineralogic origin or shear zone |

| NOTES | • | |
| 1 - Upper case s | vmbols denote a relatively strong total field s | transth |

ſ

for the ast similar to those shown on the geological map.

The VLF-EM survey has identified several strong conductor axes that trend to the east-southeast displaying an obvious detection bias in favour of the transmitter azimuth (Cutler, 098 degrees). The contours of the total field strength of most of these conductive zones conform to topographic depressions suggesting that the primary source is from conductive overburden.

The narrow conductive zones that coincide with either topographic depressions or magnetically interpreted faults are interpreted to possess structural origins, either faults or shear zones. This type of conductivity may be related to mineral origins such as sulphides, graphite or gouge along the structure, or b) an ionic effect created by water or porosity within the structure or along the upper weathered and leached edge.

The strongest conductive zone appears to be related primarily to the railroad tracks along the south side of the river valley, however there may be minor contributions from the Milnet Fault zone or the overburden within the valley.

7. Summary

An airborne combined magnetic and VLF-EM survey has been done on the property at line intervals of 100 metres. The total field and vertical gradient magnetic data, VLF-EM data and interpretation maps are produced at a scale of 1:10,000.

The magnetic data has been used to modify and update the existing geology and has shown a number of new contacts and faults. Several VLF-EM conductor axes have been identified and have been interpreted to be derived from overburden and structural sources.
