GEOLOGICAL SURVEY

and

SOIL GEOCHEMICAL SURVEY

BANNAGAN PROPERTY

Hutton Township, Ontario

Sudbury Mining District

CLAIM #s: 985559 - 985585

for

IMPERIAL METALS CORPORATION

by

R. MICHAEL JONES & DENNIS GORC

JUNE 1, 1988

TABLE OF CONTENTS

SUMMARY

A geological and soil sampling program was completed on part of the Bannagan property located 40km north of Sudbury, Ontario. The program was designed to follow-up anomalous gold values in reconnaissance soil samples taken south of Bannagan Lake.

The property covers Huronian aged Mississagi formation rocks unconformably overlying Archean basement volcanics. Quartz pebble conglomerate and polymictic conglomerate beds were found to be numerous in certain sections within the Mississagi formation.

The soil geochemical survey returned 22 samples with greater than 100ppb gold. The majority of the anomalous samples occur within a 300m by 300m area adjacent to the Vermillion River immediately south of Bannagan Lake.

Rock chip sampling of conglomerate returned a high of 73ppb gold.

1.0 INTRODUCTION

The Huronian sedimentary basin which extends from Sault St. Marie to New Liskeard, Ontario is analogous to the sedimentary basin which hosts the Witwatersand gold deposits of South Africa. Similar gold deposits may occur within the Huronian sediments near Sudbury and in May 1987 the Milnet Reconnaissance Program was undertaken to search for such deposits. The Bannagan property was one of the properties staked during this Program.

2.0 LOCATION AND ACCESS

The Bannagan property is located 40km north of Sudbury and 15km north of the town of Capreol. A very rough bush road extends 5km from the paved Moose Mountain Iron Mine road to the property. Travel time by truck from Sudbury to the property is approximately one hour each way.

3.0 CLAIM DATA

The Bannagan property consists of 27 mineral claims in Hutton Township, Sudbury Mining Division. The claims were staked in July 1987 for Imperial Metals Corporation in response to anamolous soil samples taken during the Milnet Reconnaissance Program. The claim numbers are S985559 through S985585 inclusive. The claims were recorded on July 24, 1987.

4.0 EXPLORATION HISTORY

The most recent published geological maps for the area are included in Geological Report 80, Ontario Department of Mines, 1970 by H.D. Meyn.

Exploration work for uranium on the Bannagan property was carried out by Hudson Bay Exploration in 1966, and included geological mapping trenching and diamond drilling. Several blasted trenches were opened in the conglomerate beds. A total of 16 holes for 3000 feet were completed on the northern band of conglomerate and three holes were drilled on the conglomerate near the Vermillion River. In 1976, Amax conducted a geological survey over the Bannagan property as well as helicopter radiometric and magnetometer surveys. Amax analyzed some of the conglomerate beds for gold and obtained only trace values.

Prospecting for placer gold in the Vermillion River gravels to the south of the Bannagan property has been sporadic since the late 1800's. In 1980, Kerr Addison Mines Ltd. drilled a series of reverse circulation holes in the Vermillion River gravels and found anomalous amounts of gold. H.A. Lee recommended further work to find the source of the gold to the north.

In 1987, a program of reconnaissance soil sampling by Imperial Metals found anomalous gold value in the area south of Bannagan Lake. The detailed soil survey reported on here was designed to follow-up the 1987 results.

In May, 1988 Imperial Metals Corporation completed a soil sampling and geological mapping program. A 1.2km cut and chained baseline was established south of Bannagan Lake in the area where reconnaissance soil sampling had shown anomalous values in gold. (Claims 985565 to 985570 and 985573, 75, 82, 84 were covered by the survey.) A total of 12km of north-south grid lines were chained and flagged at 100m intervals. Stations were established every 25m along the lines. A program of detailed B-horizon soil sampling totalling 550 samples of which 469 were analyzed, and geological mapping was carried out.

5.0 GENERAL GEOLOGY

The Bannagan property area is underlain by Huronian aged Bruce and Mississagi formations unconformably rested on Archean mafic volcanics. A strong northwest trending fault cuts across the property along the line of the Vermillion River.

6.0 PROPERTY GEOLOGY

Mapping was carried out along 100m spaced lines over most of the area south of Bannagan Lake and on 50m lines in the detailed grid area. The rocks were placed into two categories: 1) Archean basement mafic volcanics, and 2) Mississagi Formation. The geological survey was limited to the north and did not extend to the Bruce Formation. The Mississauga Formation was divided into: fine grained dirty quartzite, arkosic quartzite, conglomerate, and argillite.

In mapping by Amax the thin beds of conglomerate were correlated over long distances from outcrop to outcrop. Monomictic quartz pebble conglomerate west of L 0+00 was interpreted as being the same bed as the polymictic conglomerate at 4+50E 3+00N. Given the numerous thin conglomerate beds found in the mapping it is more likely that there are several beds of conglomerate within a band in te stratigraphy favourable for conglomerate.

Two bands in the stratigraphy are interpreted to contain numerous, probably discontinuous conglomerate beds as shown on the geology map. Quartz pebble conglomerate found on the property was generally clast supported with a dark grey to black, pyritic, (1-2% disseminated) quartzite matrix. Quartz pebbles average 2 - 8cm in diameter and are well rounded. The polymictic conglomerate near Bannagan Lake contains up to 25% greywacke and argillite pebbles with the remainder being quartz pebbles. Amax reported that the conglomerates are only weakly radioactive. A total of 30 samples of conglomerate were assayed for gold as part of the 1988 program and results were disappointing with the highest gold value returned being 73ppb Au (see Table 1). Sections of the stratigraphy with several conglomerate beds are the most favourable for paleoplacer gold mineralization. No evidence was found for strong cross cutting faults or hydrothermal mineralization. The rocks show little penetrative fabric or evidence of brittle deformation. However the sharp changes in strike of the beds and the contorted bedding near Bannagan Lake indicate some fold or fault activity.

7.0 SOIL GEOCHEMISTRY

A total of 550 B-horizon soil samples were taken along the grid lines and 469 samples were sent for analysis. Samples were collected every 25m over most of the grid and every 10m from L1+50E to L3+50E. Every other sample was sent for analysis from the 10m spaced samples.

The podzol soil profile was well developed and the B-horizon was usually found 10-20cm from the surface. Most of the soil has probably been glacially transported a short distance. A flat area from L0E to L4E from the Vermillion River to approximately 1+00N is covered with cobbles and sand. This material may be outwash associated with the Glaciofluival deposits in the Vermillion valley. Soil samples from this area may represent material transported over long distances.

Results returned from the soil sampling returned 22 gold values greater than 100ppb Au including 8 values greater than 400ppb Au. The highest value returned was 920ppb Au. The majority of the anomalous gold values occur within a 300m x 300m area adjacent to the Vermillion River in the vicinity of L0 to L3E. This is the same area in which the anomalous 1987 reconnaissance soil samples were taken. One should note that the soil sample results are either highly anomalous (greater than 100ppb Au) or background (1-5ppb Au) with very few intermediate gold values.

There are three likely sources of the anomalous gold returned in the soil sampling:

1. Paleoplacer gold occurring within uraniferous pyritic quartz-pebble conglomerates. The area of anomalous gold is on strike with several conglomerate horizons.

2. Outwash from the well documented Vermillion river placer gold deposits.

3. Late stage lode gold deposits along fault structures.

Additional anomalous gold values occurring near the southernmost portions of L5E through L12E are likely due to the Vermillion River gold placers.

Two anomalous values (168ppb, 270ppb Au) occur in the northern half of the grid. The source of the anomalous gold is unexplained and must be investigated.

8.0 CONCLUSIONS

1. The Bannagan Lake property in the area south of Bannagan Lake is underlain by Mississagi Formation with several beds of monomictic quartz pebble conglomerate and polymictic conglomerate. Individual conglomerate beds may be discontinuous, however, certain sections of the Mississagi Formation contain numerous beds of conglomerate.

2. No evidence was found for strong fault structures or hydrothermal mineralization.

3. Soil survey results returned 22 values of greater than 100ppb gold the majority of which were located in a 300m by 300m area adjacent to the Vermillion River south of Bannagan lake.

4. Rock chip sampling of conglomerate returned a high of 73ppb gold.

GEOPHYSICAL TECHNICAL DATA

GROUND SURVEYS – If more than one survey, specify data for each type of survey

Number of Stations _____ Number of Readings _____

Station interval _____ Line spacing _____

Profile scale _____

Contour interval _____

MAGNETIC

Instrument _____

Accuracy – Scale constant _____

Diurnal correction method _____

Base Station check-in interval (hours) _____

Base Station location and value _____

_____

ELECTROMAGNETIC

Instrument _____

Coil configuration _____

Coil separation _____

Accuracy _____

Method: ☐ Fixed transmitter ☐ Shoot back ☐ In line ☐ Parallel line

Frequency _____
(specify V.L.F. station)

Parameters measured _____

GRAVITY

Instrument _____

Scale constant _____

Corrections made _____

_____

Base station value and location _____

_____

Elevation accuracy _____

INDUCED POLARIZATION RESISTIVITY

Instrument _____

Method ☐ Time Domain ☐ Frequency Domain

Parameters – On time _____ Frequency _____

– Off time _____ Range _____

– Delay time _____

– Integration time _____

Power _____

Electrode array _____

Electrode spacing _____

Type of electrode _____

SELF POTENTIAL

Instrument _____ Range _____

Survey Method _____

_____

Corrections made _____

_____

RADIOMETRIC

Instrument _____

Values measured _____

Energy windows (levels) _____

Height of instrument _____ Background Count _____

Size of detector _____

Overburden _____

(type, depth – include outcrop map)

OTHERS (SEISMIC, DRILL WELL LOGGING ETC.)

Type of survey _____

Instrument _____

Accuracy _____

Parameters measured _____

_____

Additional information (for understanding results) _____

_____

_____

AIRBORNE SURVEYS

Type of survey(s) _____

Instrument(s) _____

(specify for each type of survey)

Accuracy _____

(specify for each type of survey)

Aircraft used _____

Sensor altitude _____

Navigation and flight path recovery method _____

_____

Aircraft altitude _____ Line Spacing _____

Miles flown over total area _____ Over claims only _____

GEOCHEMICAL SURVEY – PROCEDURE RECORD

Numbers of claims from which samples taken S985565 - 70, 73, 75, 82, 84

Total Number of Samples 550 (30)

Type of Sample Soil (Rock)
(Nature of Material)

Average Sample Weight 300g

Method of Collection grub hoe

Soil Horizon Sampled B-horizon

Horizon Development Podzol well developed

Sample Depth 10-20cm

Terrain hilly outcrops common

Drainage Development good

Estimated Range of Overburden Thickness 0-5m

SAMPLE PREPARATION
(Includes drying, screening, crushing, ashing)

Mesh size of fraction used for analysis
