OPAP 19 - 1990

M.A. TREMBLAY
JANUARY 20, 1991

SUMMARY

A total of sixty-one days were spent in the field on three projects. The budget outline of last spring was followed as closely as possible. A number of circumstances led to deviations from the path that was outlined. Most significantly was the dissolution of the partnership with Mr. Racicot. Due to his decision not to provide data or funding toward the Borden Lake Project (after the fact) the partnership was nullified. None of the data herein was collected by Mr. Racicot. Nor did he participate in either the Greenlaw or Neill Projects.

With regards the Neill Project, only three of the twenty kilometres of stream sediment sampling were completed. Due to poorer than expected access, extremely rugged terrain and in many cases the lack of proper material to sample only seven kilometres were attempted, three of which were sampled.

While working on the Greenlaw Project some time and resources went toward work in the vicinity of Phantom Lakes in neighboring Tooms Twp. Some encouraging results were encountered.

RESULTS

Encouraging results were encountered on all three projects. Sericite schists located on Borden Lake in Cochrane Twp. yielded significant values in gold. Three samples of this rock type, representing a strike length of one thousand feet, yielded values of 152, 285 and 315 ppb gold. As these results are from outcrops on Borden Lake, and as ground to the west is already staked or patented, further work to the east is suggested. What ground is available should be staked.

Further work on the Greenlaw Project is also warranted. Results from Ridout Lake and from Phantom Lakes should be followed up. Samples from Ridout yielded 165 and 586 ppb gold in a favourable geological setting. This ground should be acquired and power stripping conducted to delineate the extent of mineralization.

At Phantom Lakes samples yielded results of 182 and 213 ppb gold. This ground has been acquired. Power stripping would be useful in uncovering further mineralization.

Zinc values from the stream sampling project in Neill Twp. were very encouraging. However due to the proximity of staked mining claims, and to the likely probability that these values are due to a source on these claims, further work should be postponed until such a time as this ground can be acquired.

GREENLAW PROJECT

A total of fifteen days were spent on the Greenlaw Project. Eighteen samples were collected. Seven were analysed for twenty-six elements; these have run through the Jensen Cation Program at the Drill Core Library in Timmins. A further eleven samples were tested geochemically for gold. Of these four have shown anomalous values in gold. Samples 43507 and 43510 taken near Phantom Lakes in Tooms Twp assayed 213 and 182 ppb gold respectively. To date nine claims have been staked to cover this ground. Samples 43509 and 56960 ran 165 and 586 ppb gold respectively. These were taken from a shear zone south of Kidout Lake. These samples were taken from a creek bed and as there is little other rock exposures in the vicinity potential is good for locating further anomalous or even economic values in gold by stripping. Claim staking is planned to cover this zone.

| | Total..... | 2,414.81 |

NEILL PROJECT

A total of sixteen days were spent on the Neill Project. Eighteen stream sediment samples were collected as well as fourteen rock samples. Three of the stream samples gave anomalous (statistically) zinc values. Samples N-13, N-13 and N-14 ran 170, 225 and 270 ppm zinc. No bedrock source was located. Seven rock samples were tested for gold, none was detected. A further seven samples were analysed geochemically, the results have been analysed using the Jensen Cation method. Sulfide mineralization was detected in three location in three different settings. First is a massive sulphide zone located west of Short Lake. Second was disseminated (-½%) chalcopyrite in syenite, along Farewell Creek. Lastly pyrite and pyrrhotite in a quartz vein in Farewell Creek.

| | Total..... | 2,085.36 |

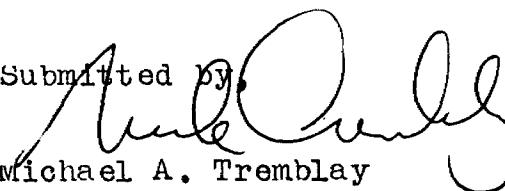

BORDEN PROJECT

A total of thirty days were spent on this project. Forty rock samples were collected. Twenty-seven samples were tested for twenty-six elements, the results of which have been analysed using the Jensen Cation method. A nice series of calc-alkaline and tholeiitic rocks has been identified. Of the thirteen samples tested for gold, three gave anomalous values. Samples 43502, 56778 and 56785 ran 285, 152 and 315 ppb. All three samples were of a sericite schist on Borden Lake. Although these values are sub-economic the fact that they exist in an unmineralized rock is quite significant. A soil geochemical survey was conducted on the four claim Cochrane Township property. A total of one hundred-fifty samples were collected and analyzed for twelve elements. These B horizon soils failed to indicate any obvious anomalies. Due to overburden conditions on the property, basal till sampling might be a more effective method to test the property. Analysis of soil results must pay careful heed to the field notes on drainage. By taking drainage into effect subtle anomalies may be encountered.

Overall rock exposure in the area was very poor. The eastern side of Borden Lake has virtually no outcroppings at all. On the Cochrane property many outcropping indicated by previous explorers were deemed to be float. To properly test conductors on the property stripping or drilling will be required.
