

COCHRANE TOWNSHIP

A total of 31 days were spent evaluating the base metal and gold potential in Cochrane Twp. Twenty rock specimens were tested for geochem gold and 32 elements scan (aqua regia 10P). Thirty-one B horizon soil samples were also tested using the above method.

A number of interesting observations were made in the area. An area 150 feet wide and 200 feet long was found to be ankeritized with up to 10% pyrrhotite mineralization associated with an intermediate pyroclastic unit on lots 7 & 8 con II (L68W-20S-Norex Grid). Sample 7524 taken in this alteration returned values of 206 Co, 356 Ni and 270 ppm Cu. Very weak quadrature max-min crossovers were noted from maps of Noranda Exploration over this zone.

A sample of rhyolite quartz-eye porphyry (7526) taken on L16W-15S returned showing 122 ppb Au and 207 ppm Cu.

A float of altered basalt (ankerite, silicified, 1% py) from L22W-9S showed 900 ppm Ni.

A sample of rhyolite (1% py) taken from the island at 26S-26E showed 356 ppb Au.

A number of silicified, hematized basalts with minor disseminated pyrite and quartz-ankerite veinlets were noted in float and in one small outcrop at L0W-0S. These appear quite similar to altered basalts associated with the Lightning Zone in the Harker-Holloway area. Sample 7517 ran 11 ppb Au.

An agglomerate unit note in 1992 on the East Block was followed westward to highway 101. Clast size and frequency are reduced to the west indicating a volcanic centre to the east.

The results of soil geochemistry on the east block were generally poor. Only slightly anomalous gold values were noted. Attempts to follow up a chalcopyrite showing were hampered by the poor exposure of bedrock in this area.

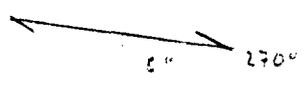

A powerstripping program planned for the west block had to be abandoned when the backhoe was unable to access the area due to wet conditions at the time.

The results of the program were positive in that anomalous values in base metals were found to occur in altered rocks associated with intermediate pyroclastic rocks (agglomerate); altered basalts noted in float and in outcrop could provide a host for gold mineralization under the right conditions; and anomalous gold values occur in the sericite schists on the east block.

Future work would have to include powerstripping, on tracked machinery, to overcome the sparsity of outcrop in the area.

Shibley-nong Kong Townships

A total of eight days were spent prospecting in Shibley, Blamey and nong kong Townships. The purpose of the program was to find base metal mineralization associated with the contact between basalts and gabbro intrusions.

Chalcopyrite was noted on the shore of a small lake near the centre of Shibley Twp. Sample 7501 ran 106 Ni, 1960 Cu and 565 Zn. This mineralization occurs near the nose of an east plunging fold. The Canadian Nickle Co. drilled a hole in the vicinity of this occurrence the collar of which could not be located.

Pyrite and pyrrhotite were also noted in the rocks along the Sultan road in Blamey Twp. Sample 7520 showed 111 Ni, 448 Cu(ppb).

Pyrite and pyrrhotite were also noted in outcrops in nong Kong Twp. but did not show colour when tested with dimethyl glyoxime.

Neill Township

The pupose of the Neill project was to follow up a stream sediment geochem program (OP-90119). The objective was to locate the source of a float found by prospectors in the 1970s that gave economic values in Ni, Co, Cu, Zn, Pb, and Ag.

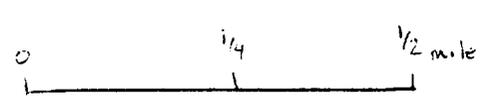

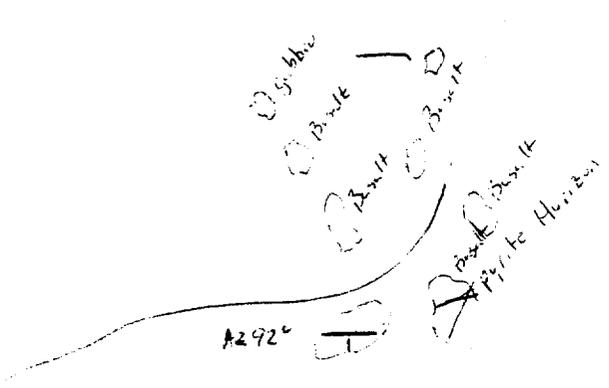

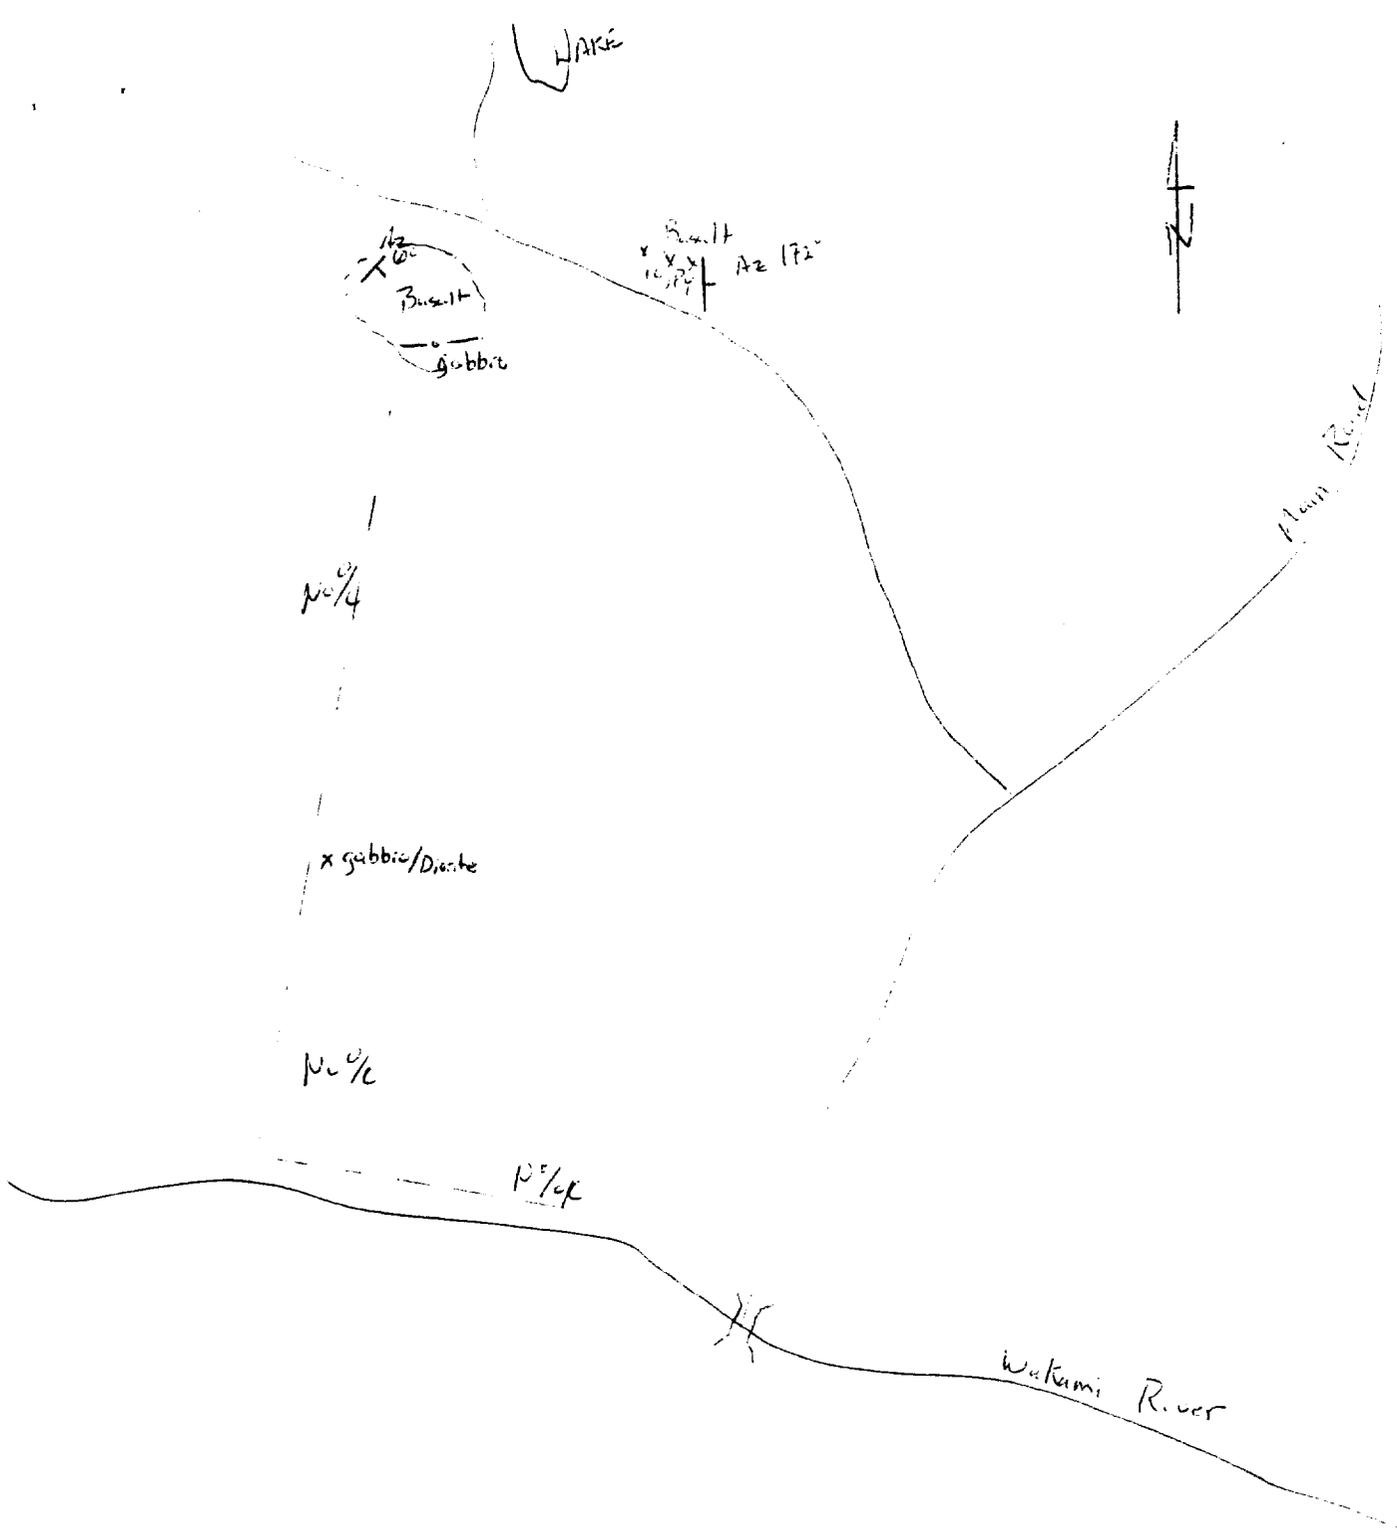

An anomalous stream sediment sample was taken in 1990 which ran in zinc. An outcrop in the stream bed is beleived to be anthophyllite. A six unit claim was staked to cover the upstream geology.

The plan was to do a reconnaissance soil geochem and VLF survey over the claim on widely spaced lines. Due to contractual obligations this could not be carried out.

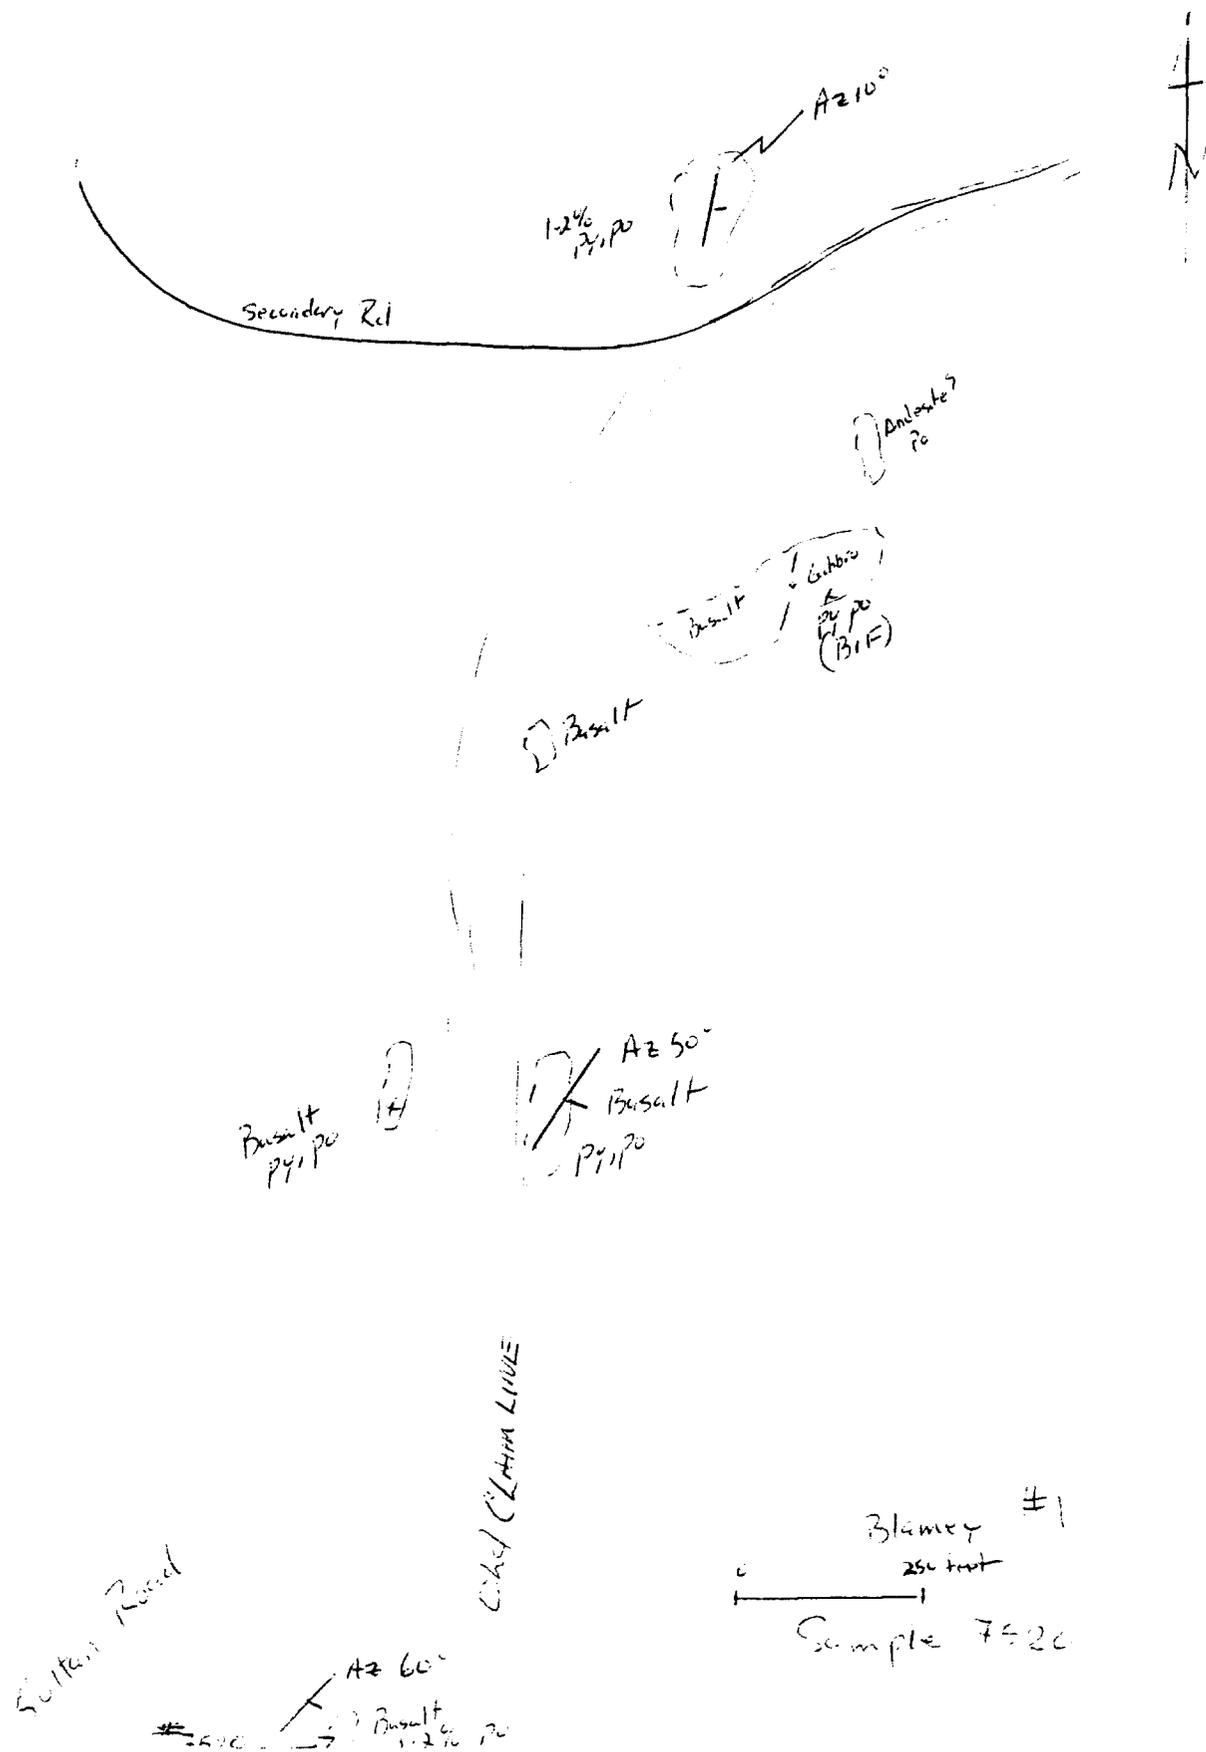

A total of seven days were spent prospecting the ground. Five bedrock specimens were shipped for analysis. Two returned anomalous values in copper (7525-1630ppb, 7512-1580ppb).

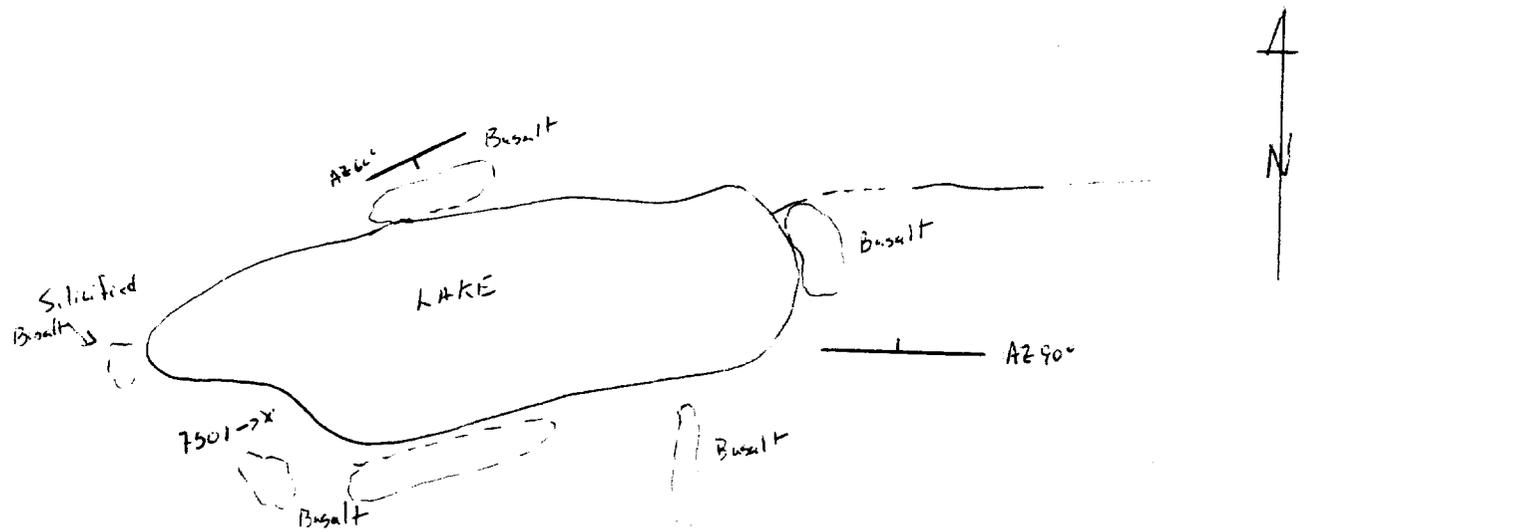

A banded iron formation was noted in the central portion of the property. Pyrite and minor pyrrhotite were noted.

Due to the presence of anthophyllite, and anomalous stream zinc values and copper values in outcrop, further work is strongly recommended in this area. The float which was found approximately one mile upstream of the property was of a basaltic gneiss with massive sulphides. It was not silicified to any degree and is not believed to have travelled far.
