REPORT ON ADDITIONAL OVERTBURDEN SAMPLING, STRIPPING AND
CHANNEL SAMPLING ON THE HEATHER LAKE CLAIM GROUP
BRYCE TOWNSHIP, LARDER LAKE MINING DIVISION, ONTARIO
(WORK CARRIED OUT FROM JULY 25 TO DECEMBER 31, 1987)

By: Raymond Davies

December 31, 1987

Examination of concentrates from basal till samples collected on the Heather Lake claim group defined a train of anomalous gold particles which originates on the property. This is confirmed by analyses on the -100 mesh fraction of the till. Backhoe trenching of the anomalous area exposed a complicated zone of shearing carrying significant gold values.

LOCATION AND ACCESS

The property lies north, south and west of Heather Lake in lots 11 and 12 of concessions II and III of Bryce township. Access is by gravel road from Earlton to a point 2 miles to the north northeast of the property. From here an excellent all-terrain-vehicle trail extends to the shore of Heather Lake on the northeastern claim of the group. Much of this trail can be traversed by four wheel drive vehicles in dry weather. Heather Lake provides access to the rest of the property.

PROPERTY AND OWNERSHIP

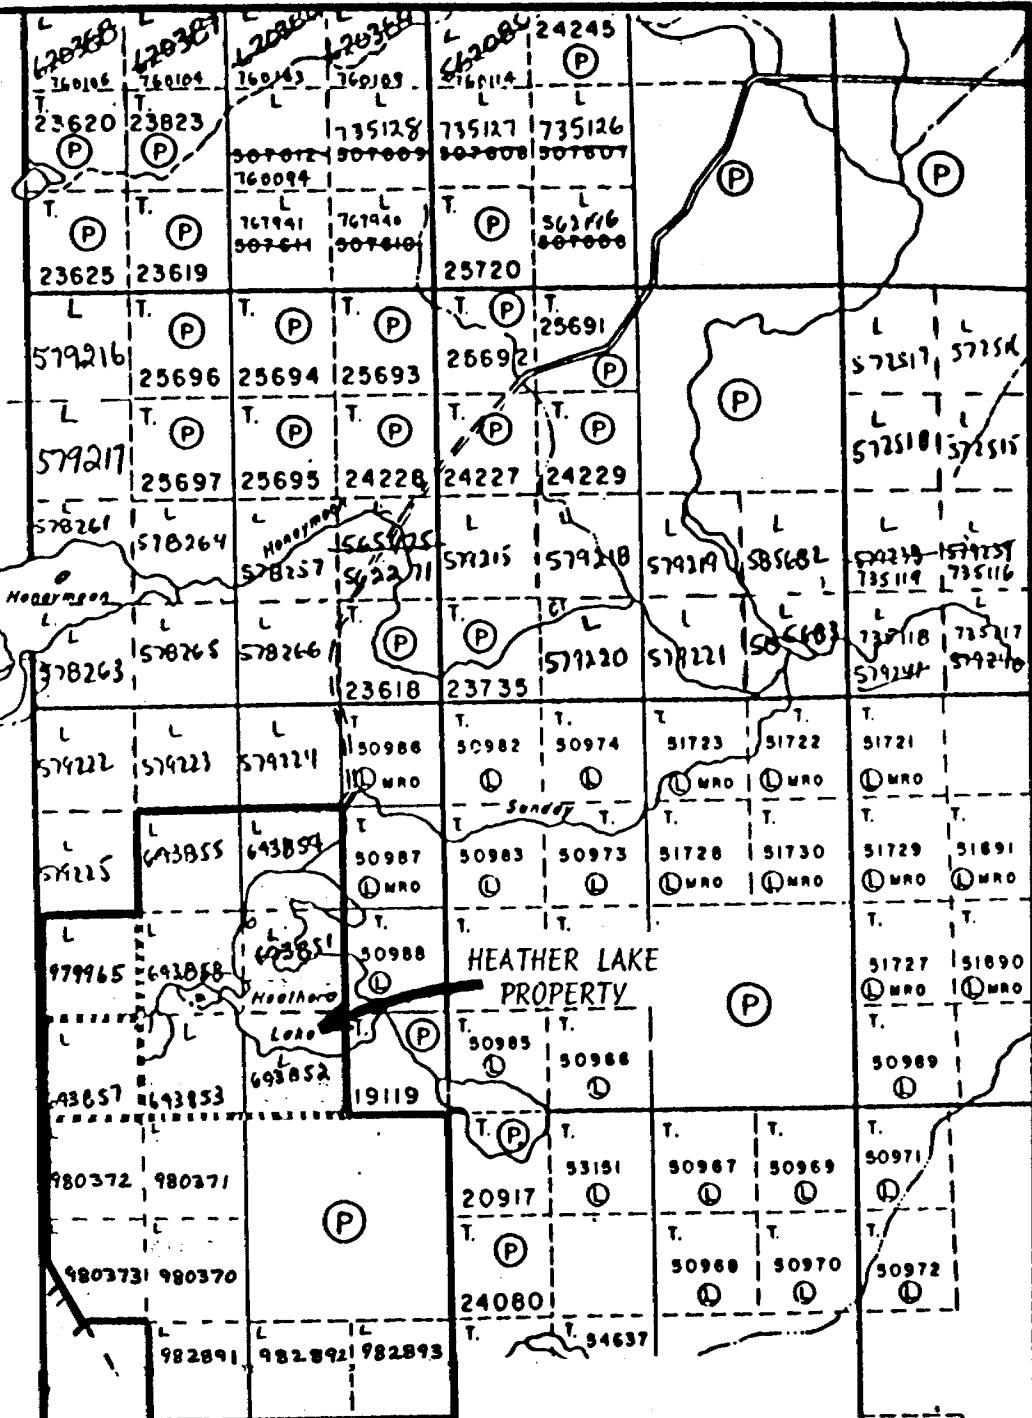

The property consists of 15 mining claims of 600 acres and one patented lot of 160 acres.

The mining claims were previously recorded in the name of James Morris of Eaglehart but have been transferred to Mingold Resources Inc. under the terms of an agreement whereby Mingold has been granted a two year option to purchase the property.

A description of the claims and the patented lot are shown below and outlined in figure 1.

PATENTED LOT - North half of lot 11 of concession 2.

Hudson Bay Exploration and Development Company Limited examined the property in 1985 and collected 4 basal till samples down-ice of a VLF electromagnetic anomaly on the north shore of the lake. The samples were not anomalous. Collection of a further 30 samples in May, June and July 1987 showed an anomalous gold particle train that appeared to originate on the property. A report on this work has been submitted as assessment work (Davies 1987). In recognition of the work that Hudson Bay Exploration and Development Company Limited had carried out, Mingold Resources Inc., an associate and successor of Hudson Bay Exploration and Development Company Limited, was granted its purchase option.

PREVIOUS WORK

In the late 1920's, pitting, trenching, sinking of a 50-foot shaft and diamond drilling was carried out on or very near the property by Heather Lake Mines Limited. Gold values over narrow widths were reported in a "discovery vein".

In 1974 a VLF electromagnetic survey was carried out over part of the property by J.G. Willars. An anomaly beneath the lake along its north shore and another west of the island in the southwestern part of the lake were outlined.

In 1980 R. Sheedy for Sylva Explorations carried out VLF-electromagnetic, magnetic and MaxMin II surveys. The magnetic survey is described as being "flat" with variations of only 200 gammas. The two electromagnetic anomalies first detected in 1974 were again recommended as drill targets.

In 1984 three diamond drill holes were drilled by C. Bush from the same collar to test the anomaly under the north part of Heather Lake. The deepest hole was 300' in length but may not have reached the target conductor. No significant gold values were obtained.

GEOLOGY

The area of the claim group has been regionally mapped as intermediate to felsic metavolcanics intruded by small quartz-porphyry and gabbro bodies and diabase dykes. Easton and Johns (1986) have presented a detailed breakdown of the geology in the vicinity of Heather Lake which is shown in figure 2. Of special interest are the pyroclastic breccias and tuff breccias trending northeast through Heather Lake in contact with an intrusive subvolcanic quartz-feldspar porphyry body. The contact coincides roughly with a weak VLF electromagnetic anomaly to the northwest of Heather Lake. The pyroclastics centred on Heather Lake are very coarse, angular, poorly sorted, unbedded and heterolithic and are interpreted as volcanic vent facies.

The quaternary geology of the property is shown on Ontario surficial geology map S465 as being essentially silty to sandy till with outwash deposits along the southern boundary. Most of the area sampled has abundant outcrop and is covered by good basal till. The regional glacial striations and the most recent glacial striations on the property indicate an ice flow to 150-160°T. An older set of striations indicating ice flow to 235°T are found in the deeper parts of the trenches excavated.

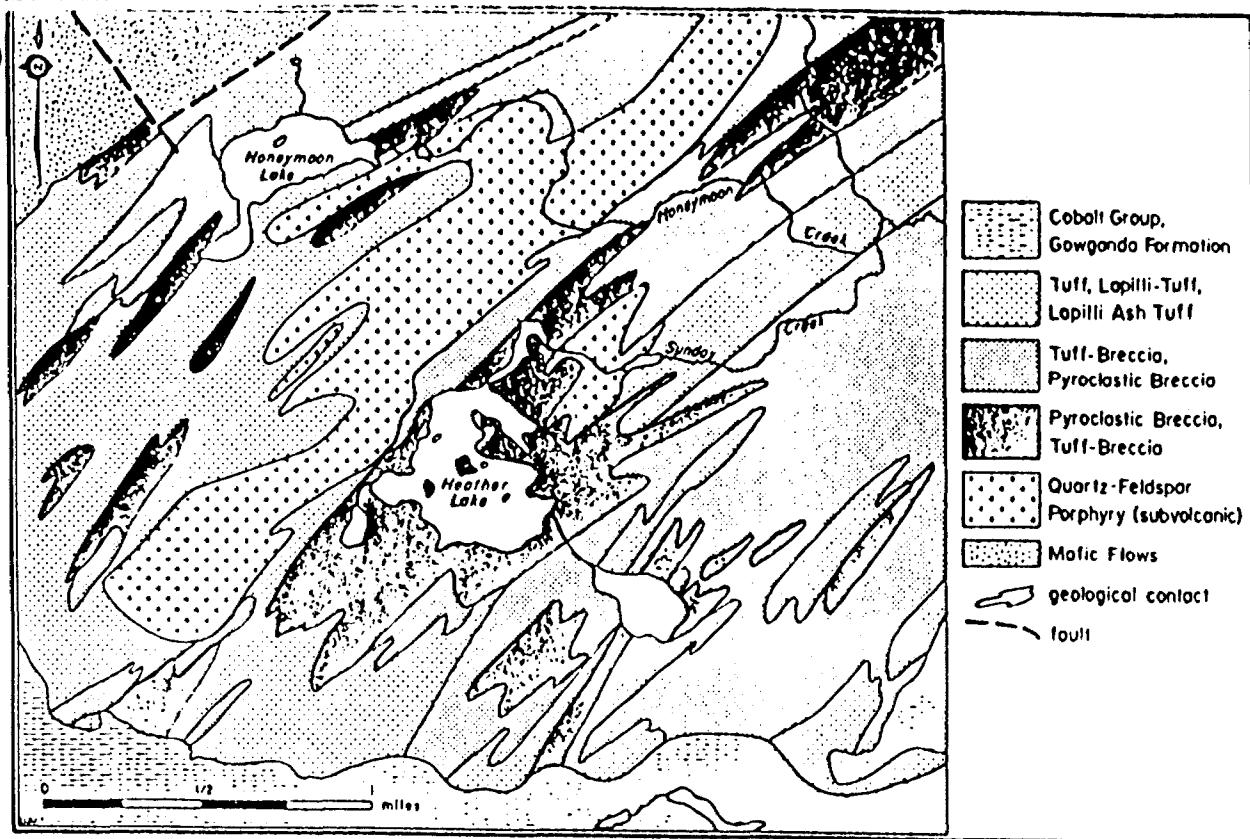

Figure 2 a Distribution of the pyroclastic rocks of the Skead Group in southern Bryce and Tidhope Townships

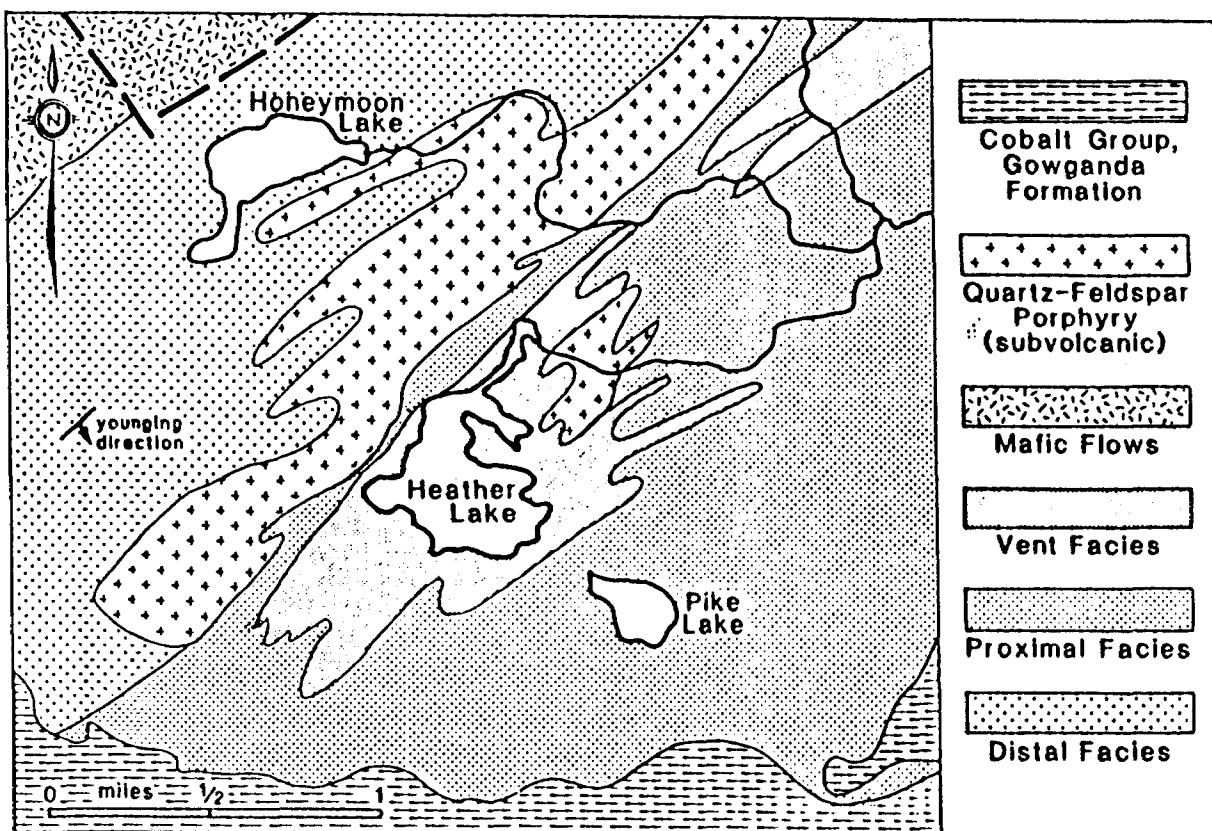

Figure 2 b Distribution of volcanic facies of the pyroclastic rocks of the Skead Group in southern Bryce and Tidhope Townships. (from Figures 1.30 and 1.31 in Easton and Johns 1986)

PERSONNEL

Work between July 25 and December 31, 1987 on the Heather Lake claim group was carried out by the following people on the dates shown:

Pestonji, Mehernosh	Sept.10-19,21-23,28-30,Oct.1-21,23-31; Nov.1-5, 7-14, 17-13, Dec.1
Etmanski, Ken	Sept.28-30; Oct.1-31; Nov.1-6, 9-14, 17-22
Hunter, Christopher	Oct.11-22, 24-25, Nov.5, 17-23
St. Jean, Jeff	July 25-31; Aug.1-31; Oct.3-4, 24-31; Nov.13-15,21,28,30
Stewart,Jill	Oct.20-21; Nov. 5
Davies, Raymond	Sept.10-11; Oct.20-21; Nov.13
Conway, Mark	July 18-19,21-31; Aug.1-3, 5-22, 24-31

All the above are employees of Mingold Resources Inc. (or its predecessor - Hudson Bay Exploration and Development Company Limited) of Box 28, Toronto-Dominion Centre, Toronto, M5K 1B8.

OVERBURDEN SAMPLING TO DEFINE GOLD ANOMALY

79 large samples of basal till weighing 15 to 30 kilograms each were collected on or near areas of bedrock at strategically located sites on the property. 34 of these samples were previously reported (Davies 1987) and had indicated a gold dispersion train with a probable source within the claim group boundary. The additional samples now reported were to define better the anomaly before it was stripped with a backhoe. At most of the large sample sites 200 grams of till were also collected for geochemical analysis and sieve analysis. Each of the samples was backpacked off the property and transported to New Liskeard where the company operates a sample processing laboratory.

The large samples were screened and the minus 0.5mm fraction was concentrated over a Deister table. Concentrates weighing approximately 100 grams were panned by hand in a black goldpan and examined for gold. The number of gold particles present was recorded and the number normalized to a standard 30 kilogram sample. Results are shown in tables 1 and 1A, figures 3 and 4.

			<u>HUDSON BAY EXPLORATION AND DEVELOPMENT CO. LTD. EASTERN DISTRICT</u>		

75 of the concentrates that had been examined for visible gold were also analysed by the neutron activation method for Au, Na, Ca, Sc, Cr, Fe, Co, Ni, Zn, As, Se, Mo, Ag, Sb, Ba, La, Ce, Sm, Eu, Yb, Lu, Hf, Ta, W, Ir, Th, Ur. Analytical results are shown in appendix 1 and the gold analyses, recalculated to micrograms gold per concentrate and then normalised to a 30 kilogram sample of original till, are shown in table 2 and some of the results are shown in figure 5.

Small samples of till weighing approximately 200 grams were submitted to X-Ray Laboratories of Toronto for sieve analysis (using 9, 32 and 100 mesh sieves) and the -100 mesh fraction was assayed for gold using the fire assay/direct current plasma method. The results are shown in table 3 and figures 6 and 7.

DISCUSSION

The 4 samples collected in 1985 (F-321 to F-324) were located on the peninsula protruding into Heather Lake to test a strong VLF electromagnetic anomaly ("A" in figures 3 and 6) up-ice and beneath the north part of the lake. Three of the samples contained no gold particles and one contained 2 gold particles which is not very anomalous. No further work was carried out until 1987.

In early June of 1987 11 samples were collected to test two VLF electromagnetic anomalies ("B" and "C" in figures 3 and 6) on the west side of Heather Lake and part of anomaly "A" that had not been properly covered in 1985. An anomalous (8, 8, and 7 colours) train was defined down-ice of anomaly "A" but also appeared from a sample containing 10 colours to originate up-ice of anomaly "A". 19 More samples were collected in late June and July north of the lake. 5 Of these samples were very anomalous containing 12 to 23 colours respectively and the anomaly appeared to be cut off in the up-ice direction. A limonite-rich rock fragment from the sample containing 23 colours assayed 90 ppb gold.

The additional 45 samples collected since July 25 to define the anomaly in more detail before it was stripped are shown in figure 4 (number of gold colours) figure 5 (weight of gold colours) and figure 7 (ppb gold in - 100 mesh).

Two interesting relations exist between the number of gold particles observed and the total gold in the -100 mesh fraction of the same samples. The most striking relation is that the number of observed gold particles drops off less rapidly down-ice from the source area than does the total gold in the -100 mesh fraction. The second relation is that the gold particles form a train above their background value whereas the total gold value in the -100 mesh fraction of the till along the gold particle train approaches closely to and is lost in its own background value.

These relations can be explained. Thick visible gold particles, in both the gold particle trains derived directly from a gold source and those in the background derived from pre-existing overburden, will be stretched out during glacial transport into thinner and more numerous, but still visible, gold particles. This will run counter to the drop-off in number of particles expected down-ice from a gold source as a result of dilution. In contrast the total gold in the -100 mesh fraction of till from a gold train will drop more quickly in value down-ice from a source in direct relation to the amount of dilution. There is evidence that the gold particles near the gold source at the head of the Heather Lake train are larger than those further down-ice as shown in table 4 and figure 8.

Gold particles both from the train and background are ultimately broken down (equally) to a point where they are no longer large enough to be observed and are then effectively removed from the train and the background. In contrast the total gold in the -100 fraction of till in a gold train is added to its background value. Gold assay trains will therefore more quickly approach their background values which are being elevated by addition of material over time and through repeated glacial advances, than gold particle trains which during the same time are losing material from their background value.

STRIPPING OF GOLD ANOMALY

A Catapillar 215 backhoe and a D7G bulldozer was contracted from K.T. Lacarte Construction of Englehart and was used to strip overburden from 7 trenches across an apparent northeast striking cut-off zone at the head of the gold particle train. Small bedrock depressions and rock surfaces in trenches 1 and 2 were washed clean with a high pressure Wajax fire pump. Parts of other trenches were also washed and water in bedrock depressions was drained with a Honda pump. The total length of the trenches was 370 meters, and 116 heavy equipment machine hours were used. The extent and location of the trenches is shown in figure 9 and a sketch of each of the trenches is shown in appendix 2.

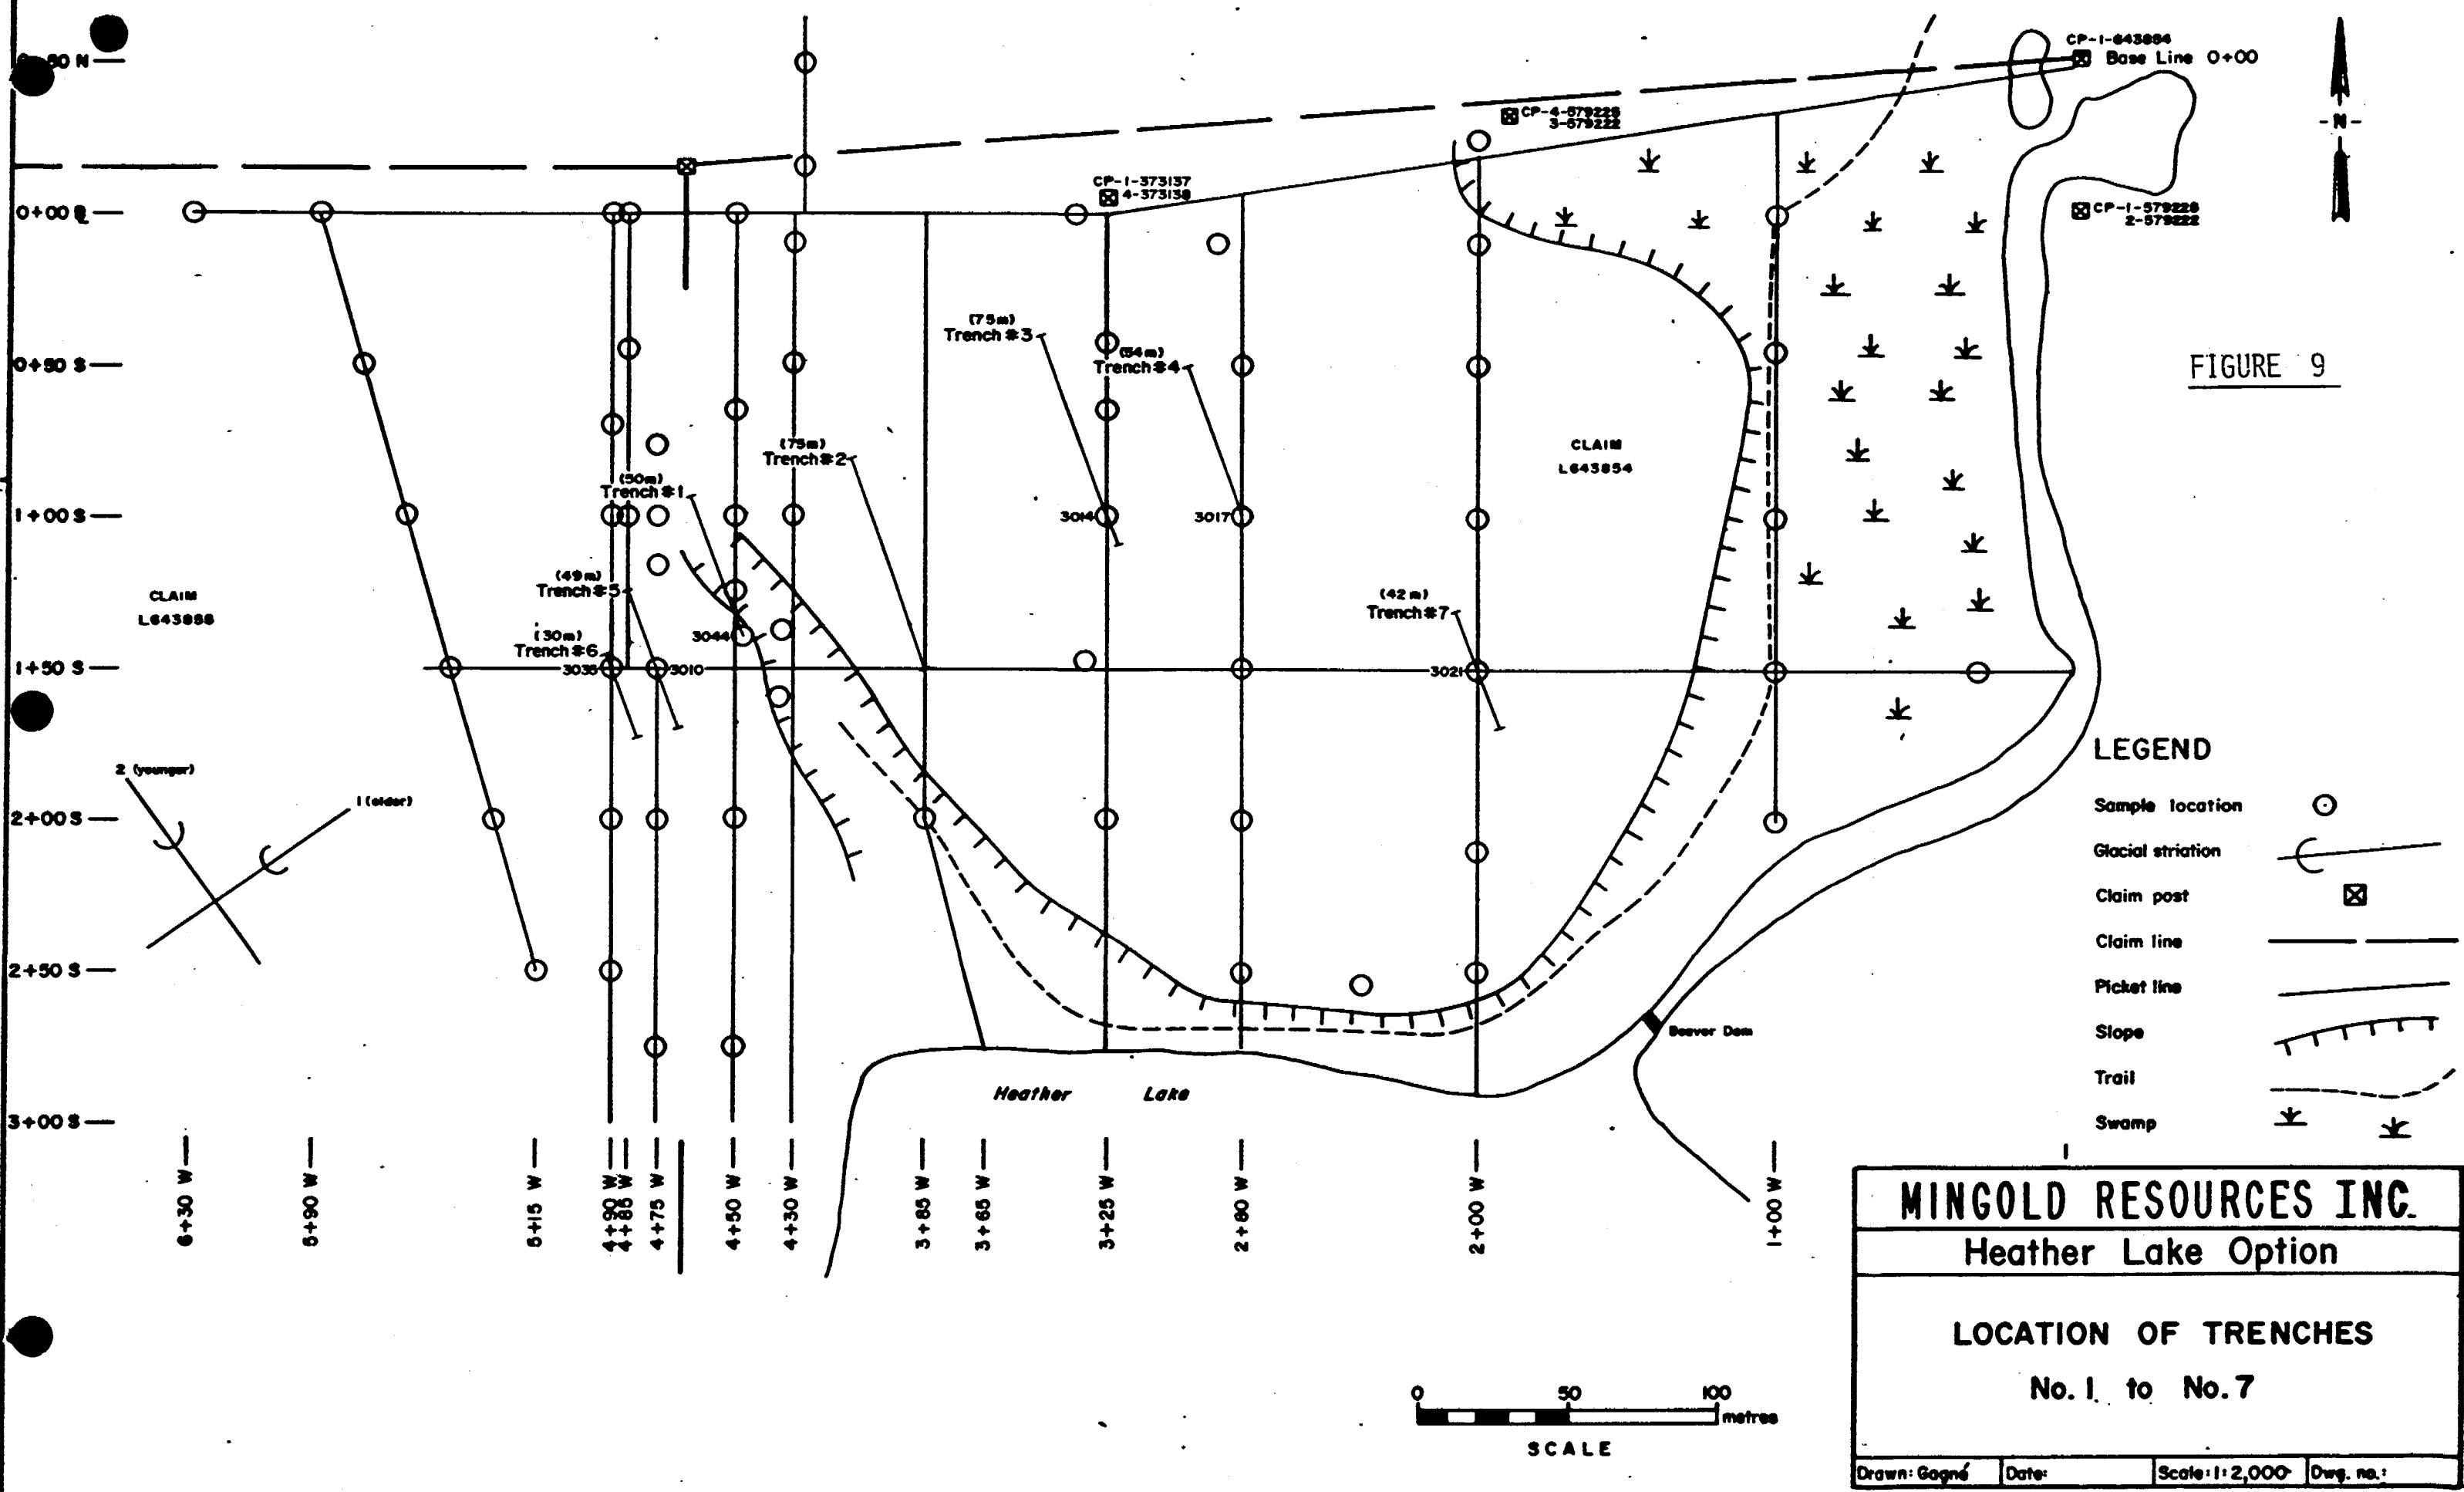

The first trench was excavated across the highest value along the cut-off zone at the head of the gold particle train. This coincides with a shallow topographic low which strikes northwest-southeast parallel to the last ice flow direction. Excavation of this trench was more difficult than expected. Large angular slabs of mineralised rock plucked from sheared bedrock were difficult to move because the till in which they were embedded was partly cemented with limonitic iron oxides. The shear zones from which the slabs came were deep bedrock depressions filled with till and had to be excavated by hand.

The deeper depressions filled with limonite cemented tills probably relate to an old ice flow direction as several of these contain striations that strike 235°T. The bedrock highs contain striations that strike 155°T and are related to the last ice flow direction.

DETAILED SAMPLING OF OVERTBURDEN IN WALLS OF TRENCH 1

11 Large samples and 55 small samples of overburden were collected from the walls of trench number 1 and processed as before to determine exactly where the gold values originate. Details of these samples are found in tables 1 and 3.

The small samples were collected from the till from the 5 cms immediately above bedrock at intervals of 5 metres along the trench starting from the original high value of 320 ppb at the down-ice end of the trench and ending at the low value of 2 ppb at the up-ice end of the trench. Samples were also taken at 30 cms intervals through the vertical till section at 6 suitable sites. The location of samples in trench 1 are shown in figure 10. The distribution of gold values in the overburden in trench 1 is shown in figure 11.

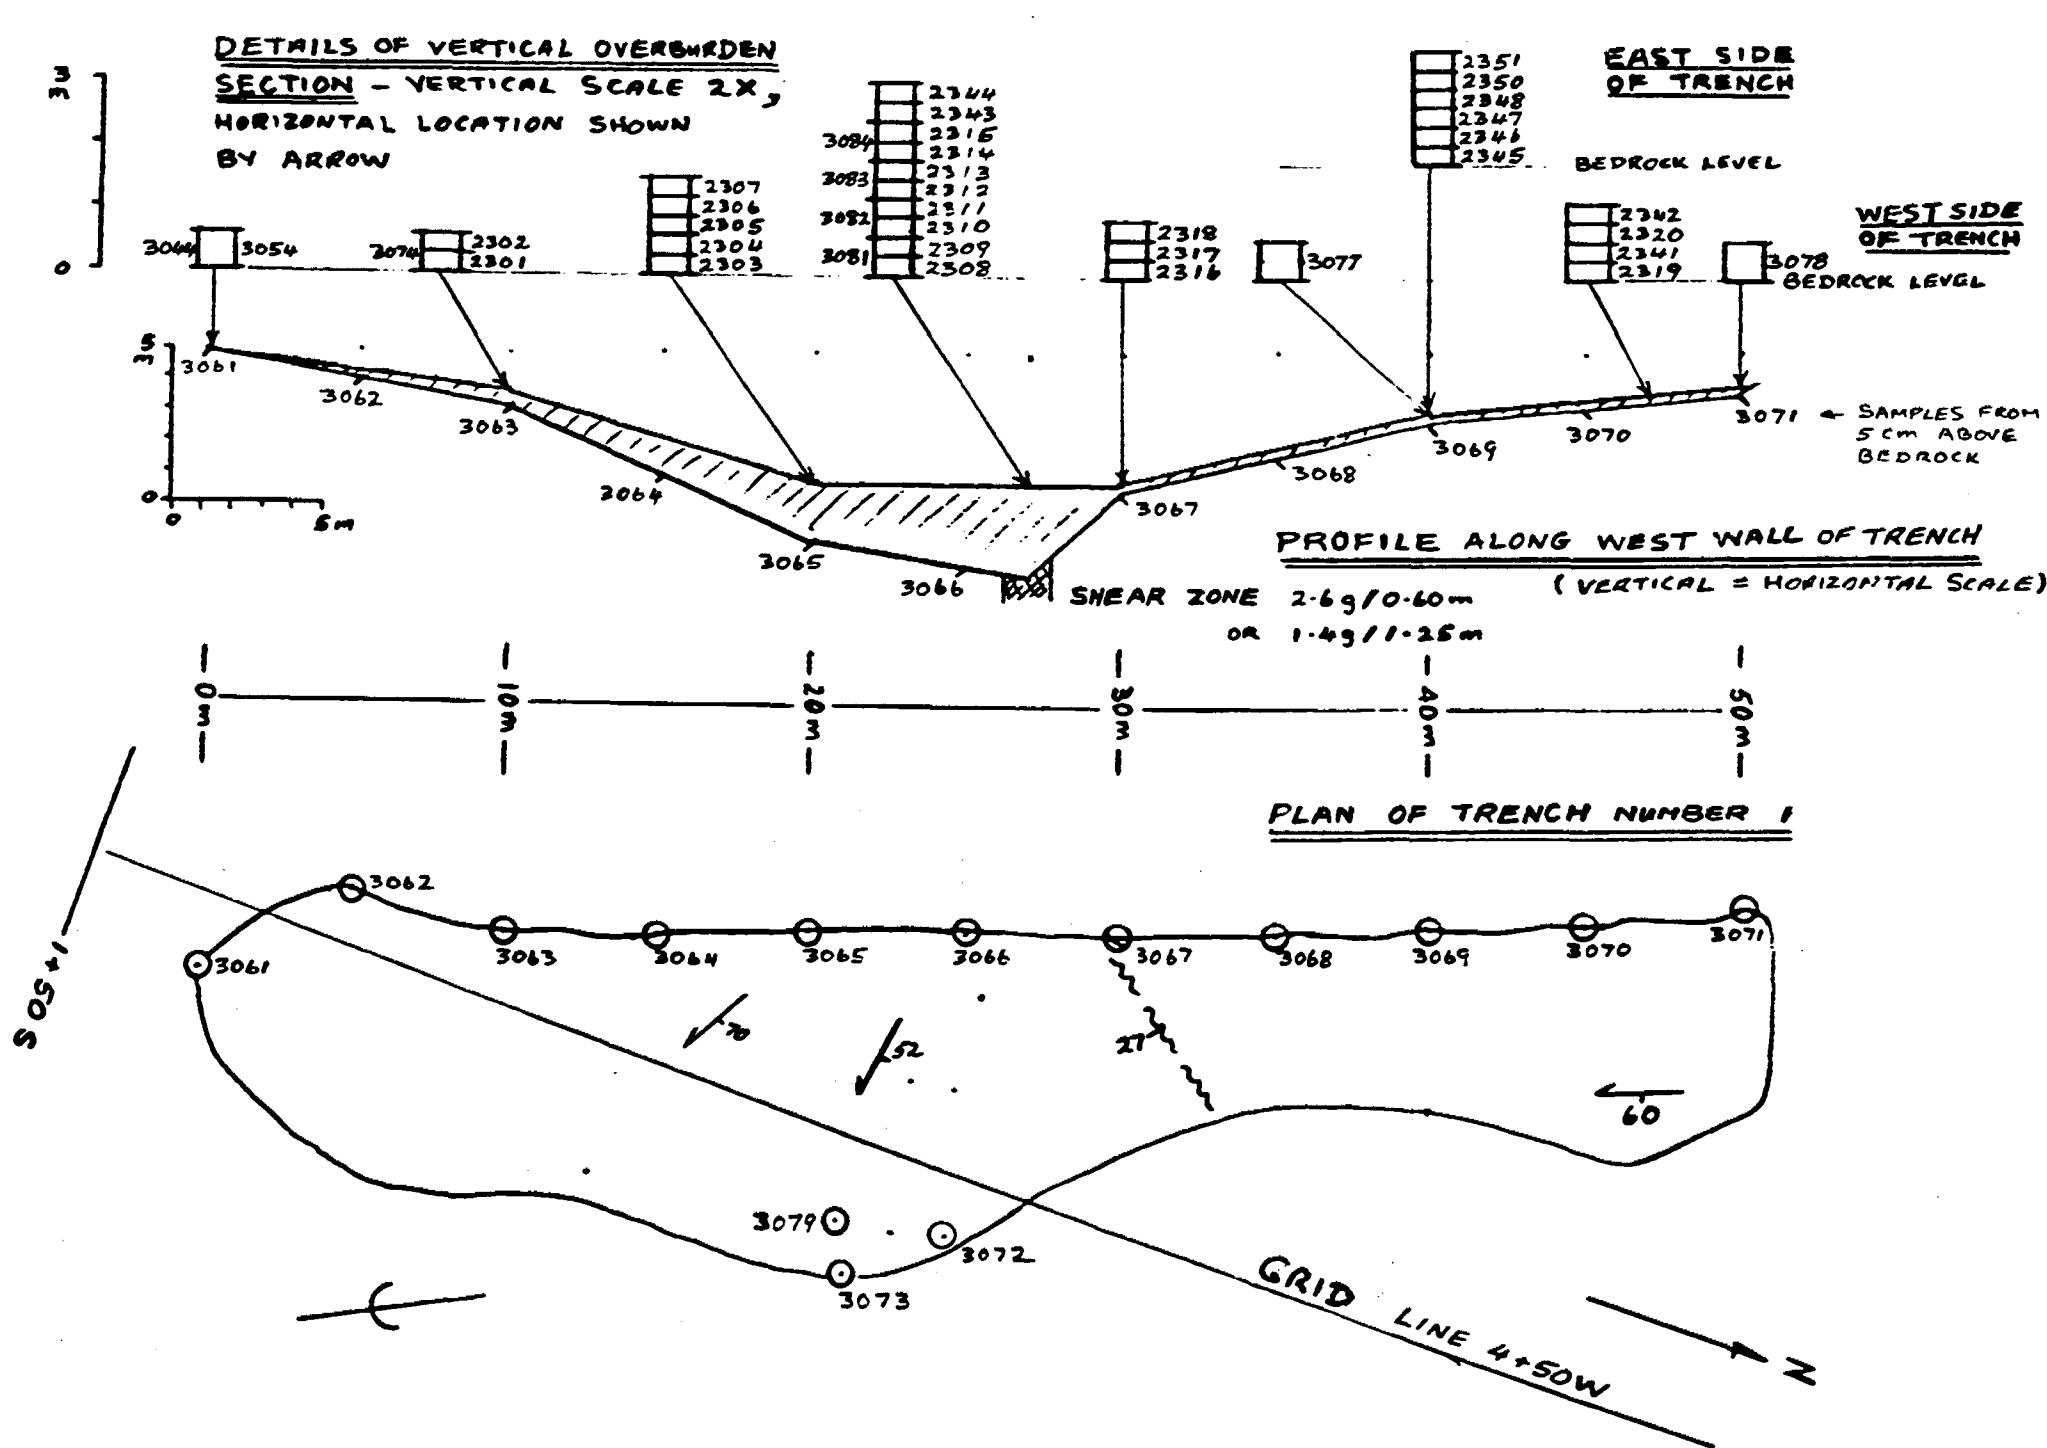

FIGURE 10 : LOCATION OF DETAILED OVERTURDEN SAMPLES IN TRENCH 1 ON HEATHER LAKE CLAIMS

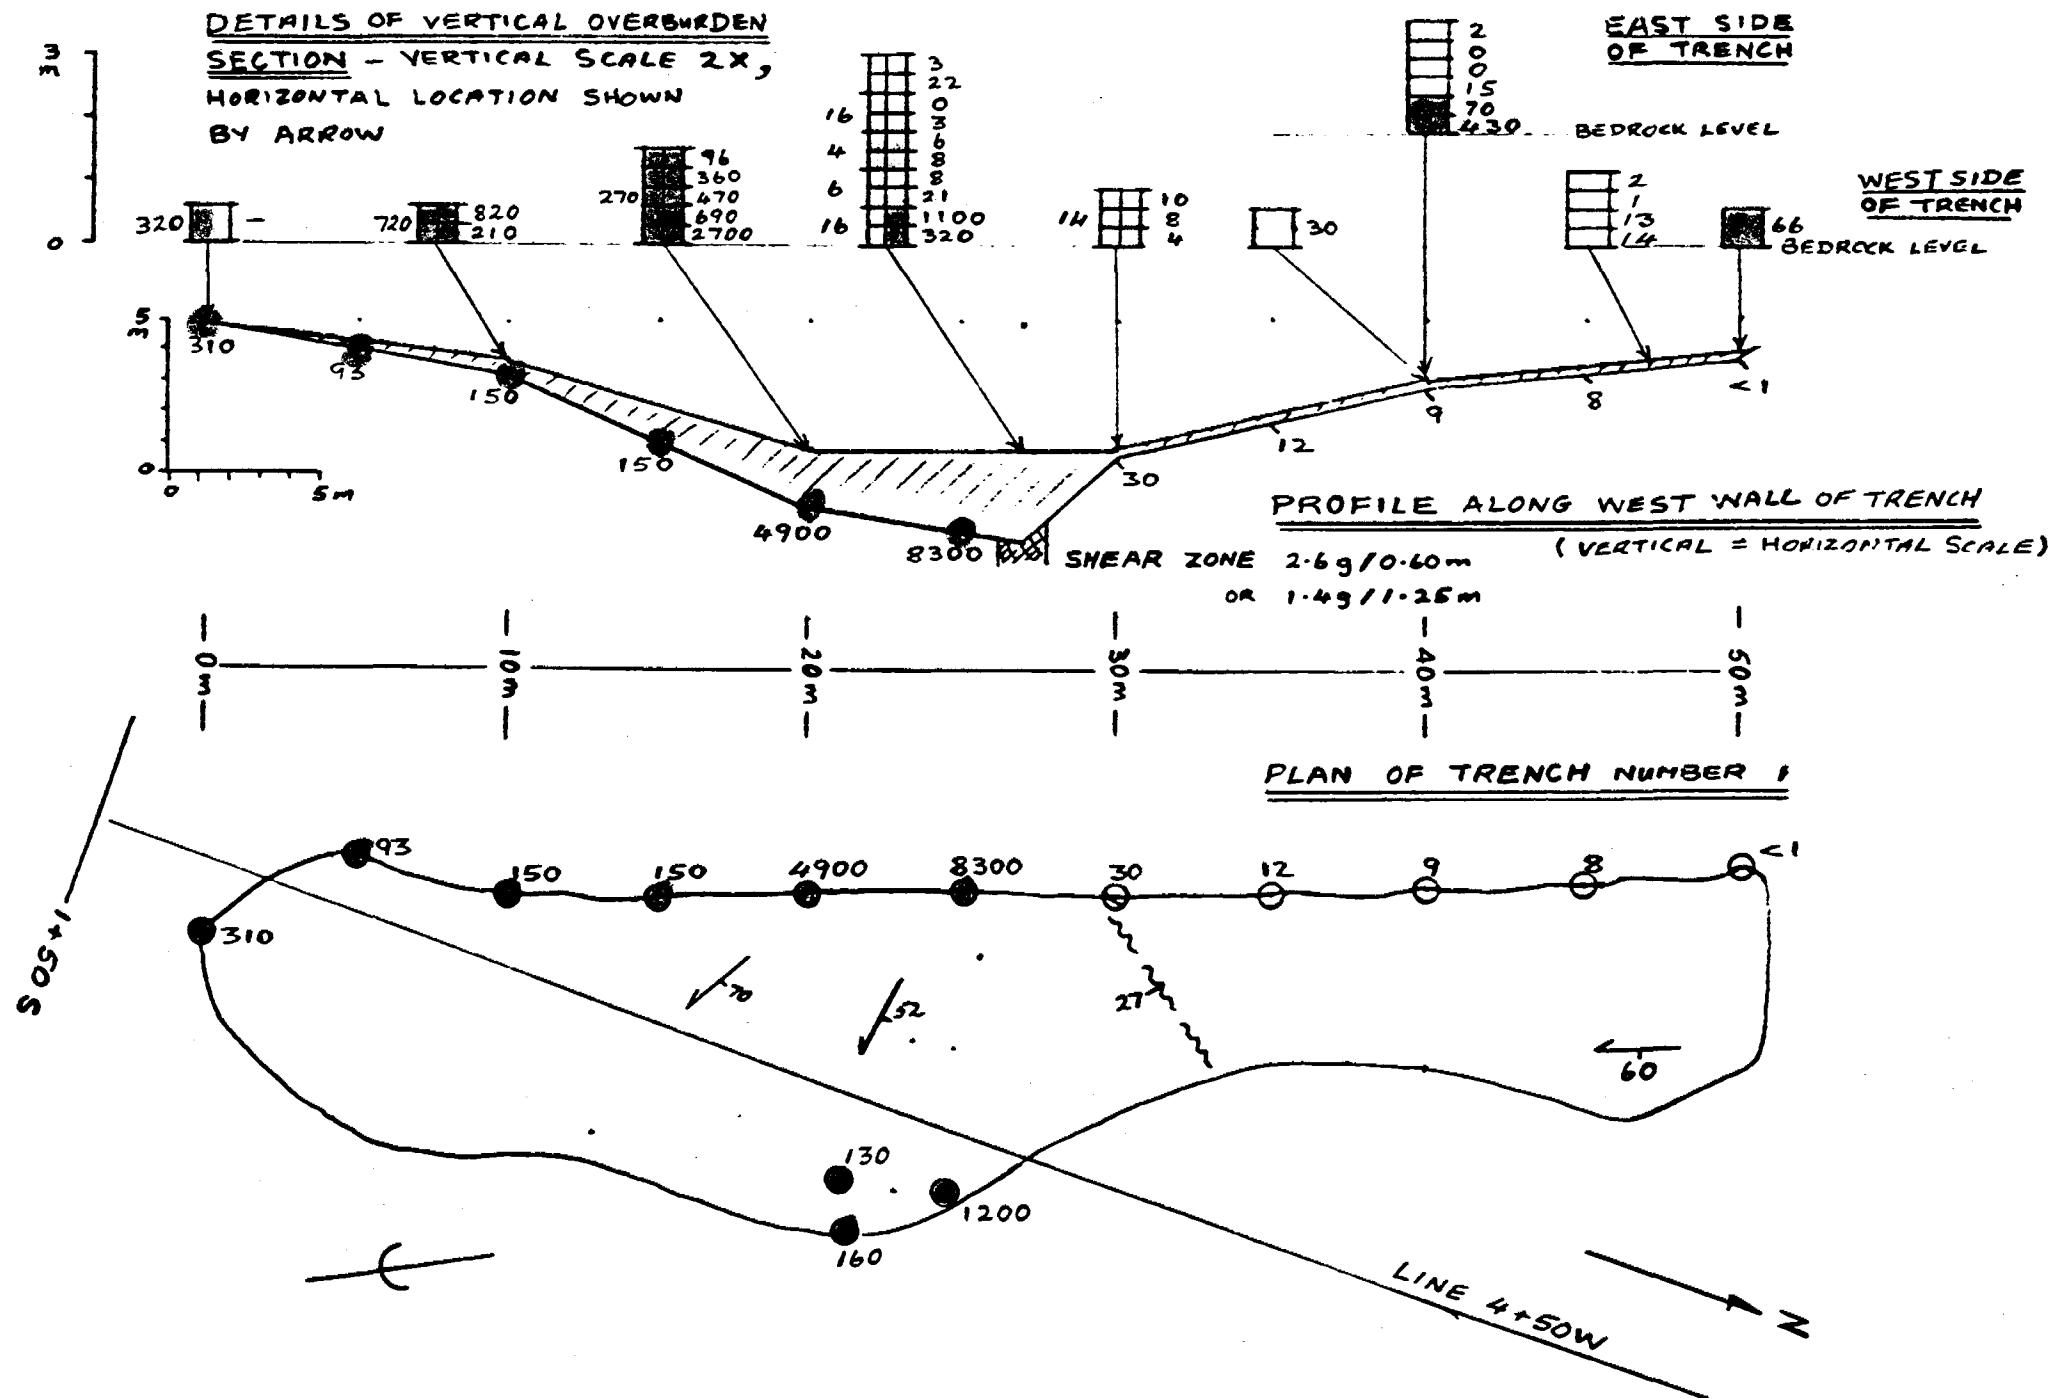

FIGURE 11 : GOLD AS PPB IN -100 MESH FRACTION OF GLACIAL TILL COLLECTED IN TRENCH 1 ON HEATHER LAKE CLAIMS

Gold values increase from the original high of 320 ppb to 8300 ppb 25 metres further up-ice at the down-ice side of the deepest part of the trench. This coincides with gold mineralization in a strong shear zone including some broken vein quartz between silicified walls containing fine pyrite. The shear zone appears to have been displaced by a cross fracture to be repeated again at the up-ice (north) end of the trench.

Eleven large till samples were collected from trench 1 at 10 meter intervals starting at the original high gold particle count of 83 at the south end of the trench and proceeding to the original low count of 4 at the north end of the trench. Four samples were also taken through the vertical section in the deepest part of the trench coincident with the mineralised shear zone.

10 Meters up-ice from the original high count is another high count of 82 particles. The counts drop to 9 particles at the 20 metre mark up-ice and to 4 particles at the 27 metre mark above the mineralized shear zone. The distribution of gold particle counts is shown in figure 12.

GRAB SAMPLES FROM TRENCHES 1

12 Grab samples were collected from various trenches before removal of the overburden was complete. The gold values are listed in table 5 and those relating to trench 1 are shown in figure 13.

The most significant gold values were obtained from trench 1. Samples taken from the deepest part of the trench returned gold values of 10,313 ppb and 25,165 ppb and were from fragments of sheared silicous rock containing pyrite.

CHANNEL SAMPLING

Channel samples at least 2" wide and 1-1/2" deep were cut across the strike of most of the bedrock exposed in trenches 1 and 2. Parts of the bedrock difficult to cut with the saw were sampled with a rock moil. This was the case in the sheared parts of trench 1 where the highest values were obtained and at the south end of trench 2 where the bedrock is very broken. For each sample an equal volume of material was taken from each point along the horizontal section sampled.

A total of 44.62 metres of channel (53 samples) was cut in trench 1 and 44.15 meters (34 samples) in trench 2. The assay values for trenches 1 and 2 are plotted in figures 14 to 16. Channel sample logs and sketches showing sample locations are contained in appendix 3.

The most significant values were obtained in a shear zone from the deepest point of trench 1. This coincides exactly with the up-ice cut-off point of the -100 mesh gold anomaly and the gold particle anomaly. It is also the point from which the high grab samples were collected. The apparent cut-off point for the gold particle anomaly is about 10 meters down-ice of the shear zone indicating perhaps that the coarse gold in the first 10 meters down-ice from the shear is still concentrated at the bedrock surface and the large 30 kilogram sample taken over a 1.5m vertical section with a shovel closest to the shear zone included very little of this part of the gold particle plume. The coarse gold may also be derived from a part of the mineralized zone not exposed in the trench as the ice flow direction is slightly oblique to the length of trench.

CONCLUSION

A gold particle dispersion train has been followed to a source in a shear zone which is exposed in backhoe trench 1 on the Heather Lake claims.

RECOMMENDATION

The mineralized shear zone which coincides with a topographic depression should be tested with at least 2 diamond drill holes located 50 feet on either side of the mineralization in trench 1. Electromagnetic anomaly "A" beneath the north part of Heather Lake may be related to the same shear zone and should be diamond drilled at the same time.

OF CHANNEL SAMPLES TAKEN
IN TRENCH 1 (values ppb)

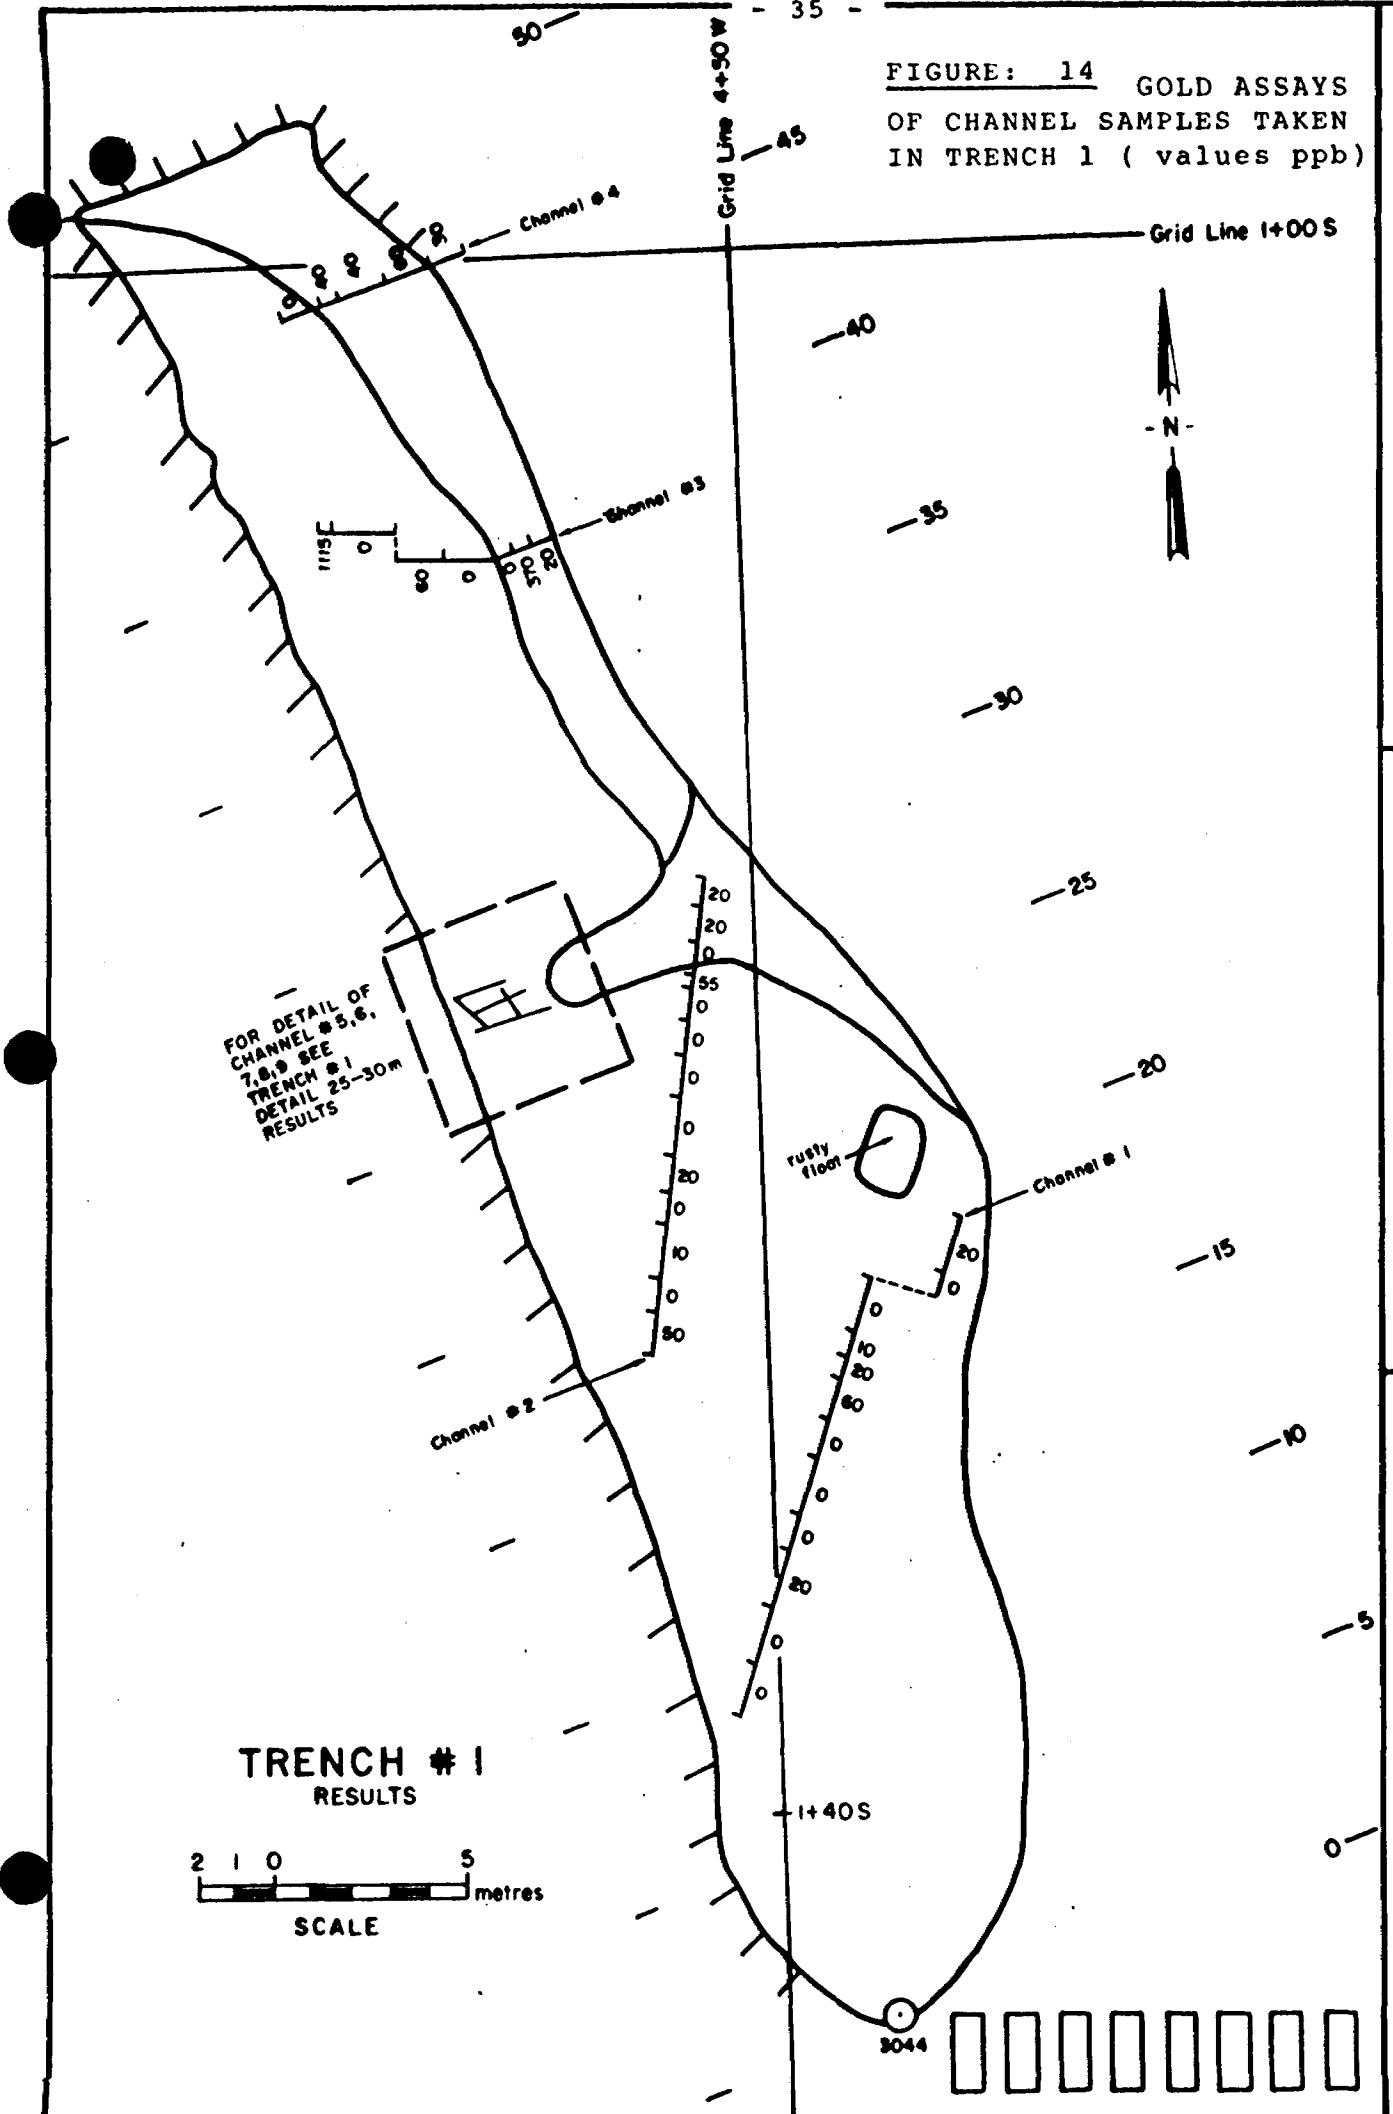

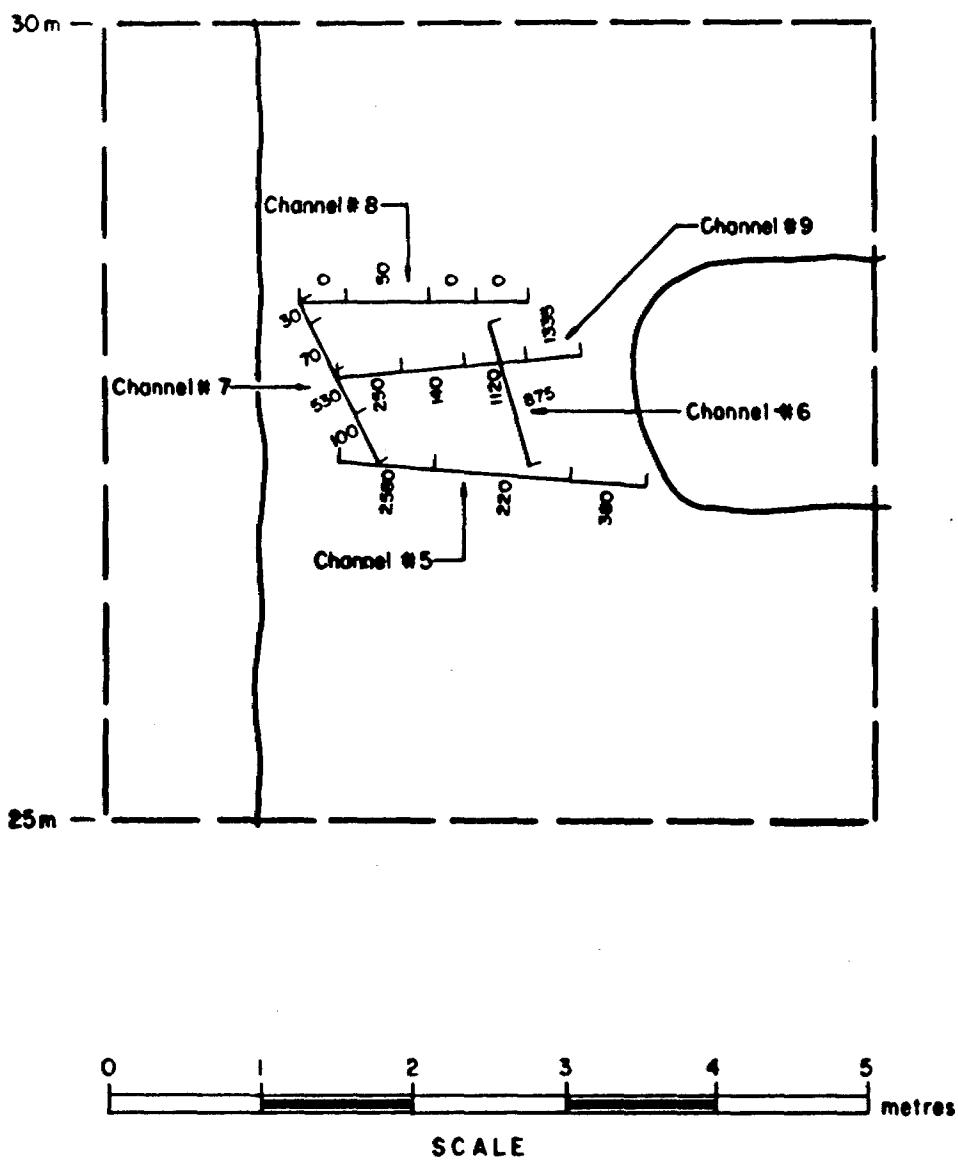

FIGURE 15 GOLD ASSAYS IN PPB OF CHANNEL

SAMPLES FROM DEEPEST PART OF TRENCH # 1

TRENCH # 1
Detail 25 to 30m
Channel 5,6,7,8 & 9

RESULTS

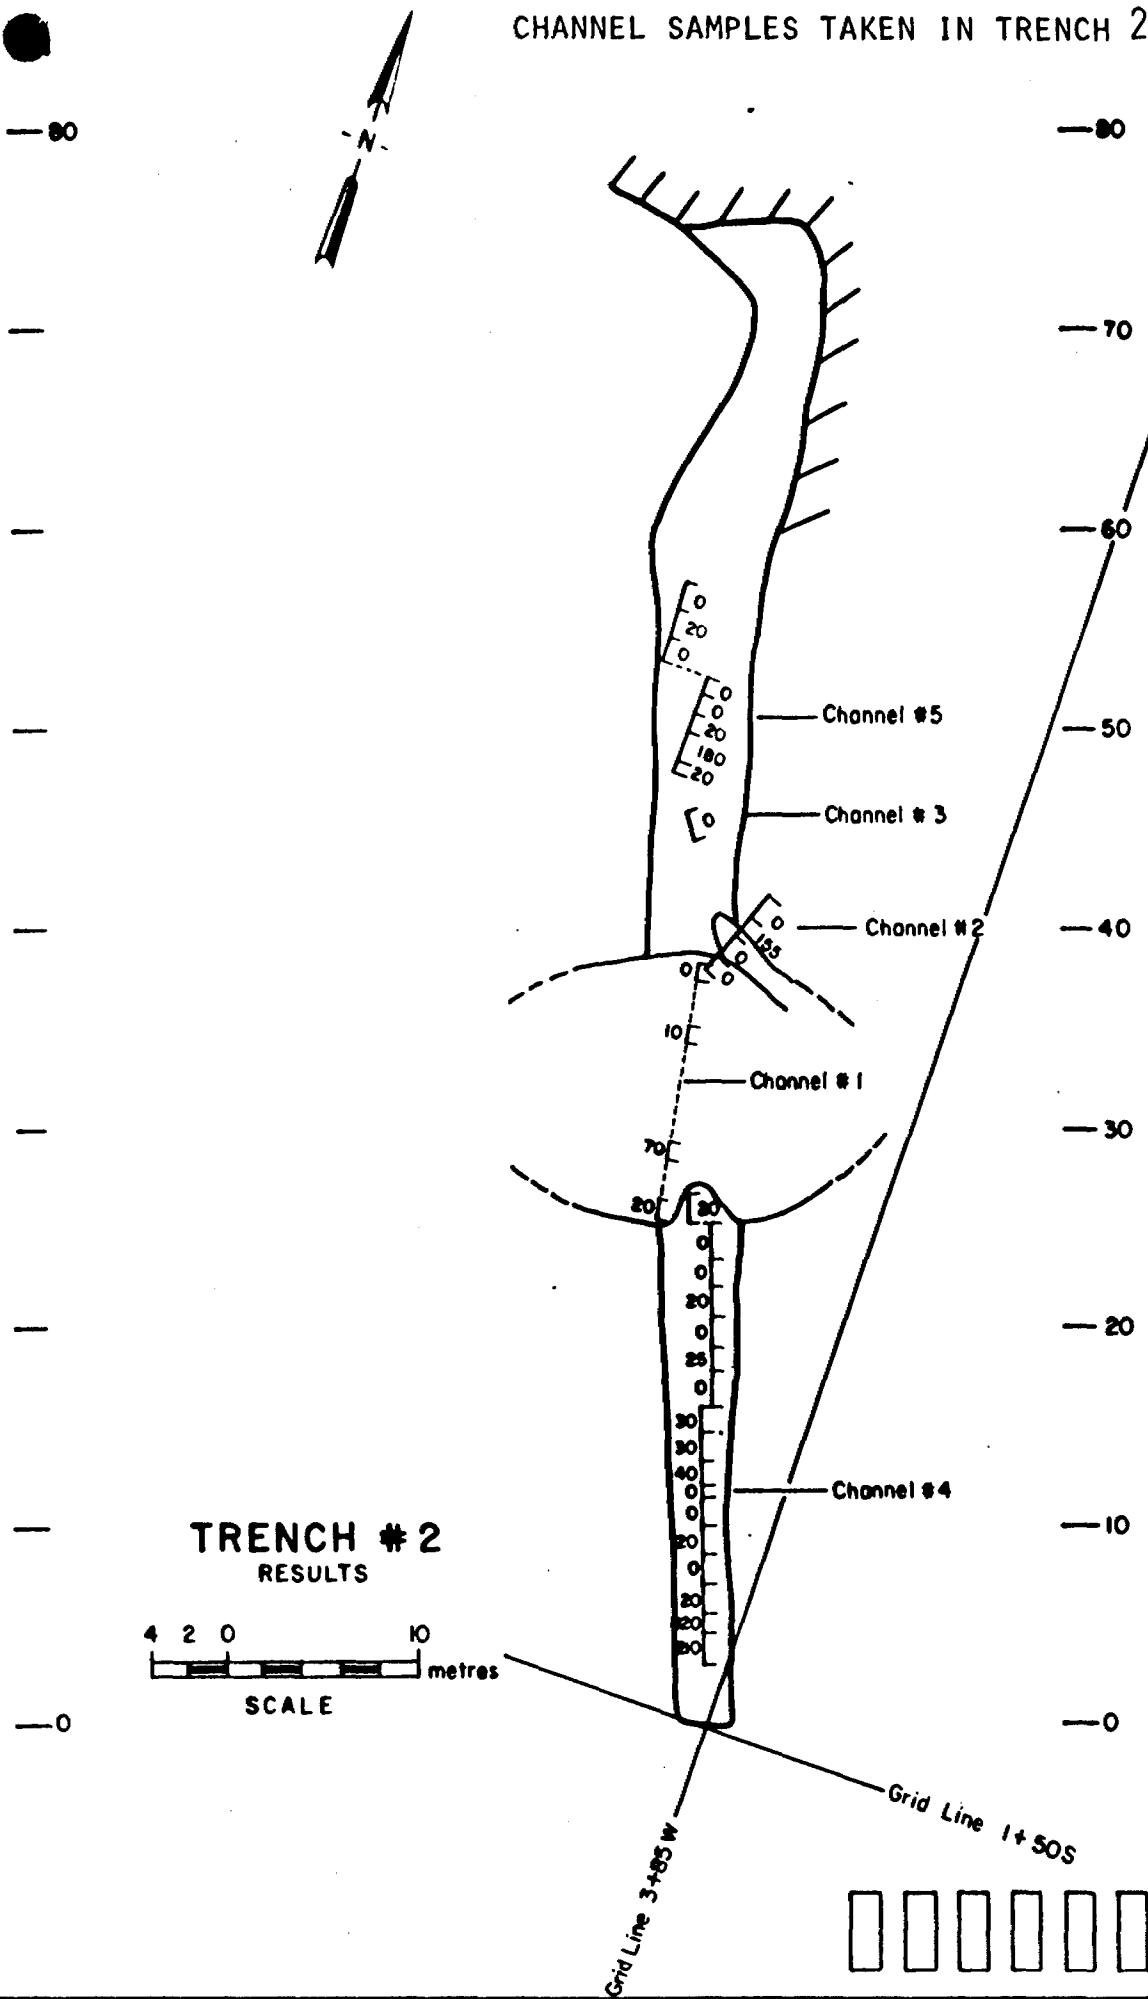

PROJECT: HEATHER LAKE OPTION
SECTION:

MINGOLD RESOURCES INC.

SCALE: 1:50 LOOKING: Plan
DATE: 15/02/88 LOGGED BY:
GROUP: Heather Lake DRAWN BY: Gemmé
CLAIM NO.: L643854 APPROVED BY:

FIGURE 16 GOLD ASSAYS IN PPB OF CHANNEL SAMPLES TAKEN IN TRENCH 2

TRENCH #2

RESULTS

A scale bar diagram consisting of a horizontal line with tick marks. The numbers 4, 2, 0 are on the left, and 10 is on the right. Below the line, the word "SCALE" is written in capital letters.

Grid Lines

A horizontal row of eight empty rectangular boxes, likely for handwriting practice or filling in information.

CERTIFICATE

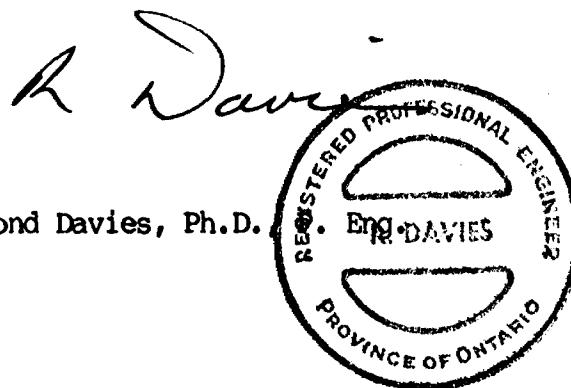

I, RAYMOND DAVIES, of the Borough of North York in the Province of Ontario hereby certify:

1. That I am a geologist employed by Mingold Resources Inc.
2. That I am a graduate of McGill University in Montreal and hold a Ph.D degree in Geology and I am a member of the Association of Professional Engineers of the province of Ontario. I have been practicing my profession for over twenty-nine years.

Dated at Toronto, Ontario this 31 day of December, 1987

31 December 1987

Raymond Davies, Ph.D.

File: T2-C5; HEATHER/LAKE
10/FEB/1988

A scale bar with markings at 4, 2, 0, and 10. The word "metres" is written below the scale.

A series of seven vertical rectangular bars of varying heights, arranged horizontally. The heights of the bars increase from left to right, creating a stepped or sawtooth pattern.
