1.0 INTRODUCTION

During the months of May and July 2003 a total of 203 soil samples were collected on claim number 1191895 in Semple Township. The samples were sent to SGS Laboratories in Toronto for MMI processing. At each field station data was collected relating to soil colour and texture and tree type. Background values were determined for each element using the average of the lower quartile of all the field data and response ratios were calculated. The element suite measured by SGS is known as MMI-B and includes nickel, cobalt, palladium, gold and silver. The exploration project was funded by an Ontario Exploration Corporation Grant.

2.0 PROPERTY LOCATION and ACCESS

Claim 1191895 lies in the south-central portion of Semple Township on the north flank of the Halliday Rhyolitic Dome and is one of four contiguous claims totalling 47 units. The UTM coordinates of the central part of 1191895 are 40695mE/5310457mN. The Semple Township Claim Map number is M-1100.

Access is via a good quality gravel road which is the southern extension of Pine St. South in Timmins and which passes within less than 30 meters of the number 3 post of 1191895. The north and south claim boundaries can be accessed by either a fair sandy sideroad heading southeast from the north end of Parting Lake or from a similar road heading east from the southeast end of Parting Lake past the north end of Cork Lake. Access within the claim boundaries proper is best obtained with the use of all terrain vehicles from the above sideroads into the vicinity of the east shore of Serpentine Lake.

3.0 GEOLOGY

The property lies in a belt of highly faulted and folded felsic and intermediate volcanic rocks intercalated with conformable ultramafic bodies. A north-south oriented glacial sand plain covers 45% of the township including 1191895. The claim itself contains a heavily overburden covered ultramafic unit described historically as a crescent-shaped magnetic body in the form of an easterly plunging anticline. (See Fig.1) It has been interpreted to be crosscut by northeast striking faults i.e. one through Swamp Lake and another adjacent to the southeast edge of the fold nose. The unit has an equivalent strike length of about 2½ miles. It has been reported to contain nickel and copper mineralization and appears to reach about 1600 feet in width in the nose area.

4.0 EXPLORATION HISTORY (See Fig.2)

<u>Dominion Gulf (MNDM File T-365, 1952)</u> drilled 20 holes totalling 8922 ft. within the crescent largely on magnetic bullseyes apparently in search of asbestos and nickel.

<u>Mining Corporation (</u>T-500, 1965) located two conductive areas within the crescent. They drilled near only one along the northwest shore of Serpentine Lake consisting of a cluster of "medium intermittent" E.M. conductors there. One hole contained a 300 ft. core run ranging from 0.35-0.41% Ni.

<u>Daniel Mining</u> (T-508, 1967) and <u>Canex Aerial</u> (T-509, 1989) targeted and completed 4 holes totalling 1726 feet. Fine acicular sulphides in Canex hole 119-5 was the only metal referred to in the logs of the 4 holes. All holes were at or near the northern tip of Serpentine Lake.

Granges (T-1643, 1973) and Falconbridge (T-3362, 1989) flew regional Mag-E.M. surveys which included 1191895 and both reported weak E.M. responses in the fold nose area but no followup appears

to have been done.

A 1990 <u>Geotem</u> airborne multi-township E.M. survey detected strong responses over 1191895 with the strongest being adjacent to the area occupied by the southern part of Serpentine Lake.

From all historical data found overburden over the nose of the crescent ranges from 42-150 ft. vertically and averaged 83 ft.

The O.E.C Grant funding was utilized to complete MMI soil sampling over the nose area and south limb of the crescent to follow up historically interesting geophysical and diamond drilling results reported there.

5.0 THE 2003 MMI SOIL GEOCHEMICAL SURVEY

A combination of rock/(old) core analyses and soil sampling was proposed to check for signs of Ni-Cu-PGE in the Serpentine Lake area. The proportion of rock/core work relative to soil analyses would be dependent on the ability of the claim holders to locate historic core and outcrops. While some scant evidence of old drill sites was located no abandoned core was found and only two small (ultramafic) outcrops were found over the fold nose area and are located near the east shore of Swamp Lake. Consequently the funding was used for soil sampling.

5.1 SOIL SAMPLING METHODOLOGY

An old narrow north-south road adjacent to the east shore of Serpentine Lake was used as a baseline for the survey grid. Perpendicular crosslines at 100 meter intervals were established along the baseline. A hip chain and compass were used to set out sample stations at 25 meter intervals along the crosslines. These stations were marked in the field with labelled blue flagging tape and labelled blazes. Red flagging was used to mark the blazed crosslines. In all, 203 samples were taken over a chained and blazed line distance of 5000 meters.

The samples on land were taken with a hand held, manually operated, four foot long steel Eijkelkamp "Dutch Auger" with a 2 inch diameter auger head.. Samples were taken consistently 10 centimeters below green vegetation in the "A" horizon. In shallow"A" horizon soil areas a combination of "A" and upper "B" horizons were taken. The bagged samples (Nasco Whirlpak plastic bags) were shipped at intervals to the SGS lab in 5 gallon plastic pails. Lake bottom samples were taken from a boat using an open shell marl-type sampler with 35 ft. of extension rods.

5.2 SAMPLE RESULTS

A copy of all SGS lab analyses is attached (See Appendix 1). A description of soils and tree cover is attached. (See Appendix 2). An assessment work summary and expenditure breakdown are included (See Appendix 3). The MMI system is described in an attachment (See Appendix 4). All MMI results are plotted at 1:5000 scale by element. (See Appendix 5).

The developers of MMI technology suggest that a background value be determined for each element assayed over all samples taken during the project. This value is the average of the lower quartile of all assayed values in the lot per element. A Response Ratio can be calculated for each element at each station by comparing the actual measured content of that element to the background of the lot.

For this sampling survey the average background levels for Ni/Co/Pd/Ag/Au are about 6/1/0.1/0.5/0.1 using the recommended criteria above.

5.3 DISCUSSION

5.3.1 BEDROCK AND MINERALIZATION

Historic drilling projects on the property were largely in search of asbestos. Consequently the core logs are very scant with respect to core descriptions other than fibre counts and the only base metal assays reported were those from one hole-i.e Mining Corporation's #2 hole (Ni). Holes drilled within the buried ultramafic unit were largely categorized as simply "peridotite".

Very fine <u>lightly disseminated sulphides</u> have been reported over core runs of 300 ft. or more in Mining Corp.'s #MC-2 and Canex Aerial's #C-119-5. These holes are collared about 800 ft. apart and drilled toward each other suggesting a fair width of such mineralization. MC-2 assays recorded 0.35-0.41%Ni /300 ft. of core. No mention of, or assays for Au or PGE's were reported.

Very fine but <u>heavily disseminated "dusty" magnetite</u> has been recorded over core runs of 500-600 ft. in Dominion Gulf holes D.G. 10 and D.G. 11. Their magnetometer survey shows a very strong anomaly with its axis over D.G.10 continuing through C-119-5. Carbonatization is known to diminish or destroy magnetism in ultramafic rocks and may account for the lesser magnetic response over such heavily altered rocks in the core of D.G. 11.

The Canex hole is likely the only one of the above four holes that is not drilled down the dip of the ultramafic structure.

No assays for Au, PGE's or Ni were recorded in D.G.10, or D.G.11.

5.3.2 MMI RESULTS

A 50-75 meter wide zone over 300 meters long along the east shore of Serpentine Lake from XL1N to XL4N gave strong Ni responses in the silty-sand shoreline banks and shallow lake water siltysand sediments (128-320 ppb Ni). Strong Ni responses also occur in similar soils over similar widths crossing the northeast shoreline of the lake from XL5N to XL6N (169-350 ppb Ni). Together the above responses suggest a 50+ meter wide zone of highly anomalous soil Ni values ranging from 20-50 times background over a strike length of about 500 meters. This zone contains all five elements measured and includes the strongest Ni, Pd, Ag and Au values and strong Co responses (20-40 times background). It contains most of the measured Pd values and 80% of the gold values (Au up to 5 times background).

A strong, more-or-less continuous, 25-50 meter wide Ni/Co/Ag/Pd response trends N-NE for over 300 meters from a point 100 meters south of XL0N on the baseline to about 150 meters east of the baseline on XL2N. This zone contains 50-80 ppb Ni (8-13times B.G.) And the strongest Co values measured (35-150 ppb) with all responses well inland from the lake shore.

Three anomalous Au responses on the NE shore of Swamp Lake (0.12 to 0.32 ppb) require followup.

6.0 INTERPRETATION

The cause of the main 500 meter long soil anomaly is currently unknown but it seems to correlate with the axis or flank of the magnetometer anomaly in the soil sample area surveyed. These coincident anomalies lie in the central to upper geometric section of the interpreted anticline and could represent a differentiated phase within the ultramafic unit.

Note: Many (but not all) of the best MMI results occur in the lake bottom samples. This result cannot be

explained or discounted at this time (e.g. acid rain?, humic acid?, springs?, gravitational sorting?, or mineralization?). Discussions with M. Fedikow (MMI Consultant) indicate that not much experience exists with lake-bottom MMI sampling. If bedrock mineralization or rock geochemistry can be positively correlated with any of the shoreline MMI results the bedrock beneath much of the lake bottom could become an exploration target.

The 300 meter long soil anomaly east of the above larger anomaly may reflect metal ion migration upward along planes of weakness at the ultramafic/felsic contact and/or shearing along the fault interpreted to run from Cork Lake to the southwest to Redstone Lake to the northeast along the southeast edge of the fold nose (fault intersection with the down-plunge extension of the anticlinal ultramafic).

Anomalous soil nickel values along the west shore of Serpentine Lake can be followed up if the above anomalies are shown to be important.

The strongest Geotem E.M. conductors correlate with the main soil anomaly on the east shore of Serpentine Lake and where it appears to be merging with the N30E soil anomaly east of the southern tip of the lake (See black squares on Appendix 5 Ni drawing). The geometric top of the anticline may in fact be the geological base of the ultramafic unit. Because komatilitic bodies tend to be mineralized toward their base (the nearby Sothman nickel deposit is one example), the 300 and 500 meter long soil anomalies on both sides of the baseline are worthy of followup.

The two outcrops adjacent to XL7N about100 meters east of Swamp Lake are ultramafic komatiitic rocks containing 35.93% MgO.

7.0 RECOMMENDATION

Because the overburden is thick in the Serpentine Lake area and the MMI survey is the only modern technology known to have been applied on this property further investigation of the encouraging findings is felt to be warranted. A modern, deep penetrating ground E.M. survey along the length of the grid covering 200 meters on each side of the baseline is recommended. A subsequent modest diamond drilling project in that area with an emphasis on Ni, Au and PGE mineralization and structure would be the most direct method of explaining the MMI anomalies.

The results of the recently flown deep-penetrating Discover Abitibi Megatem survey over the Halliday Dome are expected to be released over the next month or two and will be studied with interest by the property holders.

J.\D. Bryant, Geologi Sept.2, 2003

EXPERIENCE AND TRAINING

J.D. BRYANT

- <u>1970</u> B.Sc. Geology Michigan Technological University
- <u>1965-70</u> 4 summers field exploration in Ontario, Minnesota and Yukon. Led to development and mining of Cowley Park (copper) open pit in the Yukon.
- <u>1970-Present</u> Grass roots exploration to advanced underground exploration for gold (Australia, Tanzania, Cuba, Ontario, Quebec). Led to development and mining of the Golden 40 and Nobles Nob Extension in Australia, Bachelor Lake in Quebec and the Stock Mine in Ontario.

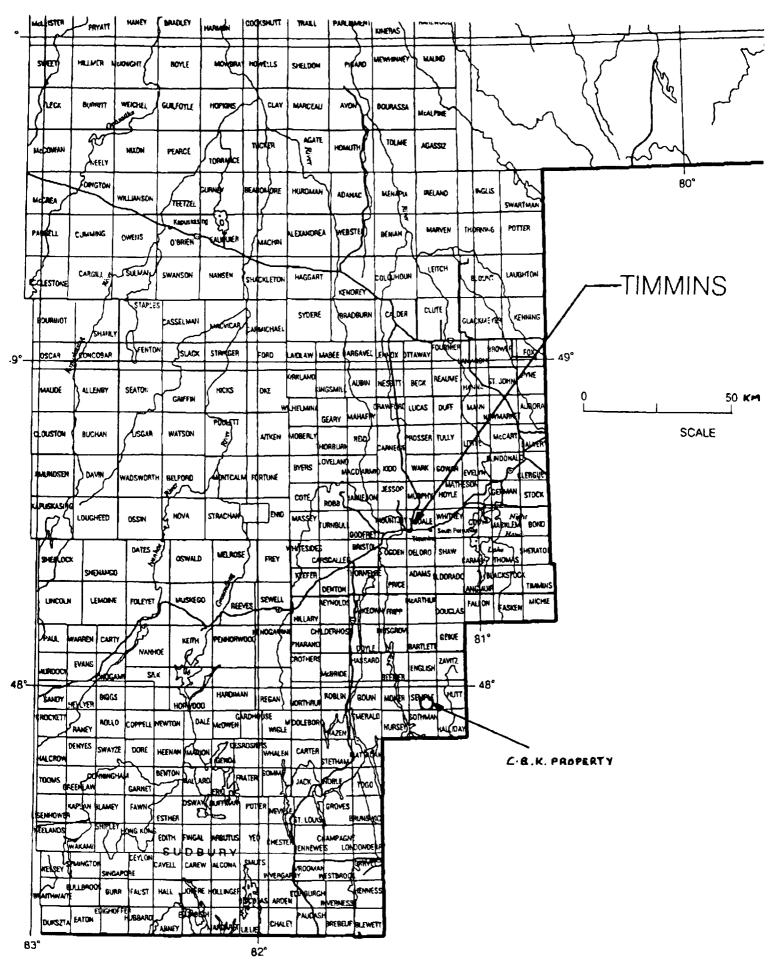

Grass roots exploration for base metals (Ontario, Newfoundland).

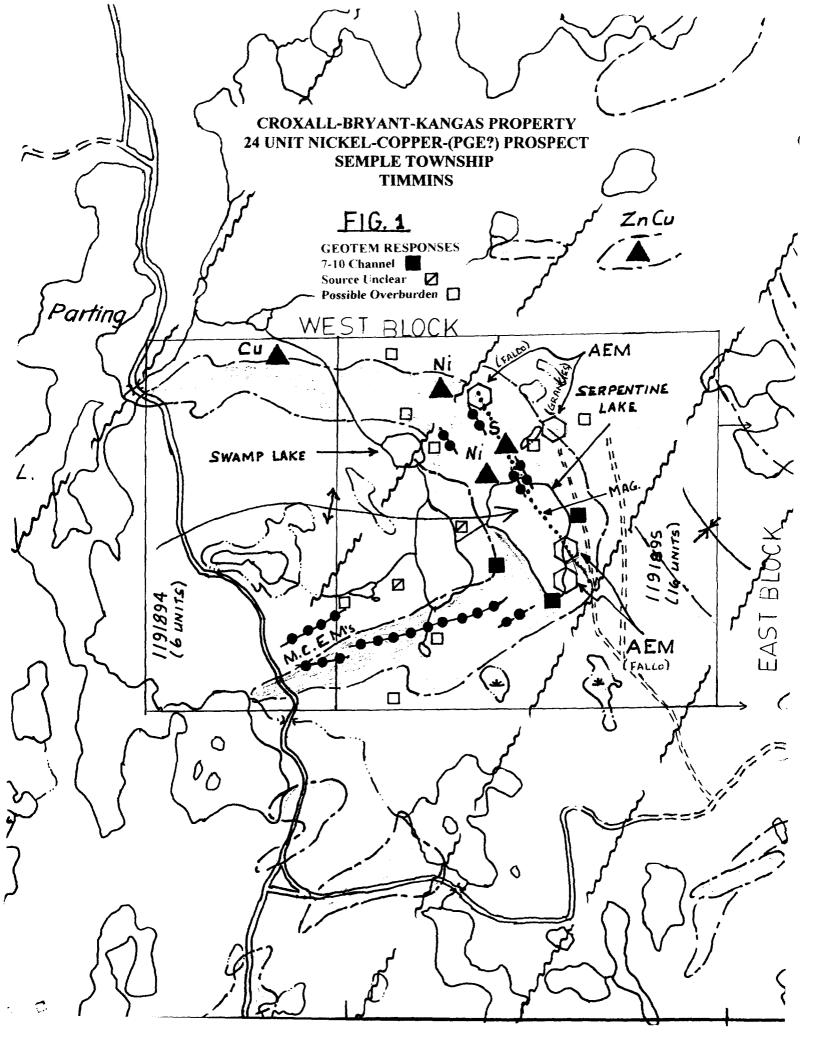

Followed advancements in exploration techniques, geophysics (ground and airborne), surveying (underground and surface) and geochemistry. Recently had the opportunity for hands on development of optimum MMI sampling depths and procedures for Northern Ontario - a partnered effort between Cross Lake Minerals Ltd. and SGS/XRAL Laboratories.

APPENDIX 4

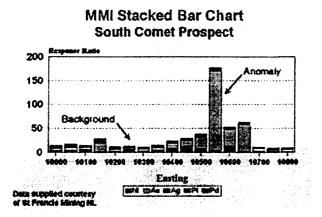

Theory, Methodology and Interpretation of MMI Results

Using Response Ratios

To obtain maximum benefit from MMI data, it is recommended that Response Ratios be calculated. Response Ratios are not a 'magical' enhancement of the data. They are merely a way of highlighting samples that are a signal (anomalous) to those which are background. There are several advantages in using Response Ratios;

Highlight anomalous samples from background

Facilitate multi-element data presentations for interpretation. An example of this is the stacked bar chart shown below. By using Response Ratios all the elements can be plotted using the same scale even though the analytical data for Ni may be an order of magnitude higher than the Au responses.

Reduce effects of dissolution variables eg temp, time. Allows accurate splicing of two data sets if they were done at separate times.

Reduce effects of sampling in different regolith units. If sample grid covers areas that have markedly different regolith, such as relict versus depositional, then the sample data can be treated accordingly to minimize the effect of sampling across different regolith units.

Calculating Response Ratios;

From an analytical data base select an element e.g. Au

Select the lowest quartile (25%) of the data for that element

Anything less than detection limit is included - use a value of half the detection limit e.g. if Au < 0.25ppb use 0.125ppb

Find the mean (average) of the lowest quartile = This is the BACKGROUND for that element

For each sample divide the element response by the BACKGROUND value. Round to whole numbers => 1. These are the RESPONSE RATIOS. **Sample Grid Design** – it is important that the sample grid and orientation are correctly designed to maximise the information from the survey. Some points to consider include strike and direction of geology, expected target mineralisation size, and style of mineralisation expected.

Sample Collection – MMI analyses only require a sample size between 300-500g. Samples need to be collected at the surface* between 5 and 20cm depth, using a shovel. Samples should be sieved using a plastic –5mm mesh sieve. Samples should then be placed into plastic snap seal bags, do not use calico bags.

*surveys conducted in locations of active deposition and transport need to be taken with extreme care. In some areas this may require samples to be taken at a specific horizon in the soil, because the surface soil is too 'active' and has not had time to establish a mobile ion signal. For more information see technical update <u>MMI Sampling in - Technical Bulletin 01.</u>

It is highly recommended, before any sampling is undertaken, that the <u>MMI</u> <u>Information Manual</u> be obtained and read thoroughly.

Quality Control – as with all geochemical analyses, check standards and duplicates need to be inserted into the sample sequence for quality assurance and control.

Sample Submission – Samples need to be submitted to a laboratory licensed by MMI Technology.

Analyses – Need to determine what type of MMI analysis is required. Currently five MMI digestions are offered.

Digest A (Base Metals):

Digest B (Precious Metals)

Digest C (Carbonates):

Digest D (Diamonds):

Digest F (Pathfinders):

Digest G (Pegmatites):

Discounts apply if samples analysed for both A and B digest element suites.

Data Handling and Interpretation - When MMI data is received from the laboratory it needs to be interpreted. The use of <u>Response Ratios</u> is highly recommended when interpreting MMI data. Response Ratios help to identify anomalous samples (high) from those samples which are background.

• MMI responses are related to a source, are not displaced, and do not form 'negative anomalies'.

Where will MMI work?

MMI has been used world-wide with remarkable success. Some of the types of climates and environments to which it has been applied include:

- Tropical rainforest
- Temperate rainforest
- Savannah
- Woodland
- Peatland
- Alpine regions
- Deserts

MMI has been used in climates varying from heavy rainfall to dry desert conditions. MMI is not limited to these types of environments, and MMI Technology recommends that companies conduct orientation surveys before embarking on large exploration programmes.

Which environments provide most difficulty?

Where physical or chemical processes produce a barrier to the surface migration of metal ions, most geochemical techniques will have difficulty in detecting metal response, and anomalies in surficial soils. Active alluvial channels which provide a physical barrier, and deep, transgressive carbonate units which provide a chemical barrier to migration are examples of this. In such environments, both orientation studies and expert advice are imperative. If you have any concerns or queries regarding the applicability of MMI in certain environments or mineralization styles, please contact us at info@mmigeochem.com.

How to use MMI

(Applying MMI Geochemistry in the field)

The MMI Technique has been designed to be a simple, robust method for explorationists to apply in the field. The technique does however require some careful planning and deliberation before being applied to survey sites. Some information is given below on how to conduct an MMI survey. This is a guide only. For more detailed information, refer to the <u>MMI Information Manual</u>, which can be downloaded free of charge.

The steps involved in completing a successful MMI survey are:

Orientation Survey - not essential but can provide valuable information on whether MMI is responding in soils across that area. Highly recommended in areas of highly transported and/or depositional soils. These initial surveys provide a lot of data prior to large surveys being completed;

2. Is substrate independent

0	extracts unbound metals attached to clays, organic matter, iron oxides, etc.
o	does not require a specific substrate, e.g. MnO ₂
	3. Samples the A horizon of soils (5-15 cm below surface)
0	avoids B horizon sampling problems
0	sampling is cheaper, and easier to access
	4. Utilizes strong ligands to retain metals in solution after extraction
0	prevents re-adsorption of metals
0	allows Au to be analyzed with confidence
0	provides more reproducible results
	5. Produces sharp positive anomalies for easy, direct interpretation
0	accurate siting of drilling over mineralization
0	no rabbit's ears, negative anomalies
o	does not rely on electro-geochemical cells
	6. Discriminates against surface transported material
0	highlights "active" source areas of metals
0	of special use in laterites, carbonates, areas with cover
0	highlights targets in conventional "corridors"
	7. Is high resolution geochemistry
0	better signal to noise ratio for detecting deep sources
0	better spatial resolution for drill targeting
	The Advantages of MMI

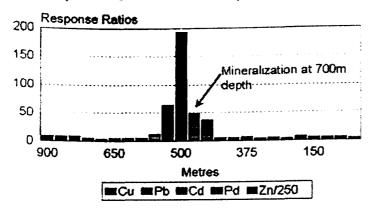

MMI has proved in general, to be more successful than conventional or other partial geochemical techniques because:

- MMI has been successfully used in difficult depositional/transported environments. In these environments MMI could accurately define mineralization deeply buried beneath layers of depositional and transported material whereas conventional techniques failed;
- MMI anomalies are more defined than conventional geochemistry, offering a more precise location of primary mineralization and providing a more accurate drill target;
- MMI is more effective over a larger spectrum of regolith units, from residual to depositional;

Base Metal Case Study

(Stacked Bar Chart of MMI Response Ratios)

By successfully measuring the mobile metal ion content in soils, MMI can give explorationists an accurate 'picture' of what lies beneath the surface:

- MMI anomalies are very sharp and precise;
- MMI responses occur directly above mineralization and updip;
- Defined anomalies allow companies to save up to 50% in exploration cost by reducing the need for broad scale drilling programmes;
- MMI provides an ideal tool for defining and prioritizing geophysical targets don't waste exploration dollars drilling unnecessary holes.

If you have any concerns or queries regarding the applicability of MMI in certain environments or mineralization styles, please contact us at <u>info@mmigeochem.com</u>.

What is the difference between MMI and other geochemical methods?

MMI (MOBILE METAL ION) geochemistry:

1. Primarily targets ore elements

0	Cu, Pb, Zn, Cd (MMI suite A)
0	Au, Ag, Ni, Co and Pd (MMI suite B)
0	Cu, Pb, Zn, Cd (MMI suite C)
0	Ni, Co, Pd, Nb, Cr and Mg (MMI suite D)
0	As, Sb, Hg, Mo, Se and Fe (MMI suite F)
0	U, Th, Pb, Ta, W and Sn (MMI suite G)

The MMI Process®

In order to successfully measure these ions, an integrated package has been developed called the MMI Process[®]. Using specially designed chemical extraction techniques the mobile ions attached to soil particles are released into solutions. These solutions are then analysed for their Mobile Metal Ion content.

The MMI Process analyses for commodity elements, which are found in orebodies. These are,

Digest A (Base Metals):	Zn. Cd
Digest B (Precious Metals):	06666
Digest C (Carbonates):	Zn, Cd
Digest D (Diamonds):	ND CO Mg
Digest F (Pathfinders):	Sb Allg AMo Se
Digest G (Pegmatites):	

MMI Analyses are available from commercial laboratories around the world. MMI Technology has licensed these laboratories. Small sample requirements have enabled companies to successfully use the MMI Process worldwide and in remote locations.

Characteristics of MMI Geochemistry

The MMI Process is an Advanced Technique: The MMI Process offers the mining industry a very powerful surface exploration tool. By successfully measuring the mobile metal ion content in soils, MMI can give explorationists an accurate 'picture' of what lies beneath the surface. Shown in the graph below is a case study where MMI was conducted over a base metal deposit. Note that the ore-body is at 700m depth in a deeply weathered, residual environment. The highest MMI responses (anomaly) re directly above the ore-body.

The following MMI theory, methodology and interpretation is quoted directly from the <u>info@mmigeochem.com</u> web site to provide background material for this survey method.

The MMI Theory - What is MMI Geochemistry

Mobile Metal lons is a term used to describe ions which have moved in the weathering zone and that are only weakly or loosely attached to surface soil particles. It is a widely held belief that these Mobile Metal lons are transported from deeply-buried ore bodies to the surface. Scientists from around the world have been studying this phenomenon for many years.

No-one is completely clear on exactly how the metal ions migrate to the surface. However, research and case studies over known ore-bodies have shown that mobile metal ions accumulate in surface soils above mineralization, indicating that the metals are derived from the mineralization source. The diagram below demonstrates a hypothetical model by which mobile ions are released from ore bodies, migrate vertically and accumulate in surface soils.

As the ions reach the surface, they attach themselves weakly to the soil particles. These are the ions that are measured by the MMI Technique to find mineralization at depths. The weakly attached ions are at very low concentrations. Because the ions have recently arrived to the surface they provide a precise 'signal' on where the ore-bodies are.

When the mobile metal ions have arrived at the surface they have a limited lifetime as 'mobile' ions. At the surface the ions are subject to weathering and are bound up by soil forming processes (i.e. they become part of the soil). The diagram below demonstrates this process. Note that bound ions (yellow) are subject to lateral movement away from the mineralization. The mobile ions (blue), however, do not move away from the source (mineralization) because they have a limited lifetime before they are converted to a bound form.

By only measuring the mobile metal ions in the surface soils, MMI Geochemistry will produce very sharp responses (anomalies) directly over the source of mobile ions. This source is ore-bodies at depth, which emit metal ions, which make up that ore-body. For example a Cu, Pb, Zn base metal deposit will emit (release) Cu, Pb and Zn ions.

Dear Sir or Madam

P4N 7N9

Subject: Approval of Assessment Work

We have approved your Assessment Work Submission with the above noted Transaction Number(s). The attached Work Report Summary indicates the results of the approval.

At the discretion of the Ministry, the assessment work performed on the mining lands noted in this work report may be subject to inspection and/or investigation at any time.

If you have any question regarding this correspondence, please contact PIERRE DESCOTEAUX by email at pierre.descoteaux@ndm.gov.on.ca or by phone at (705) 670-5858.

Yours Sincerely,

Ron Gashinski Senior Manager, Mining Lands Section

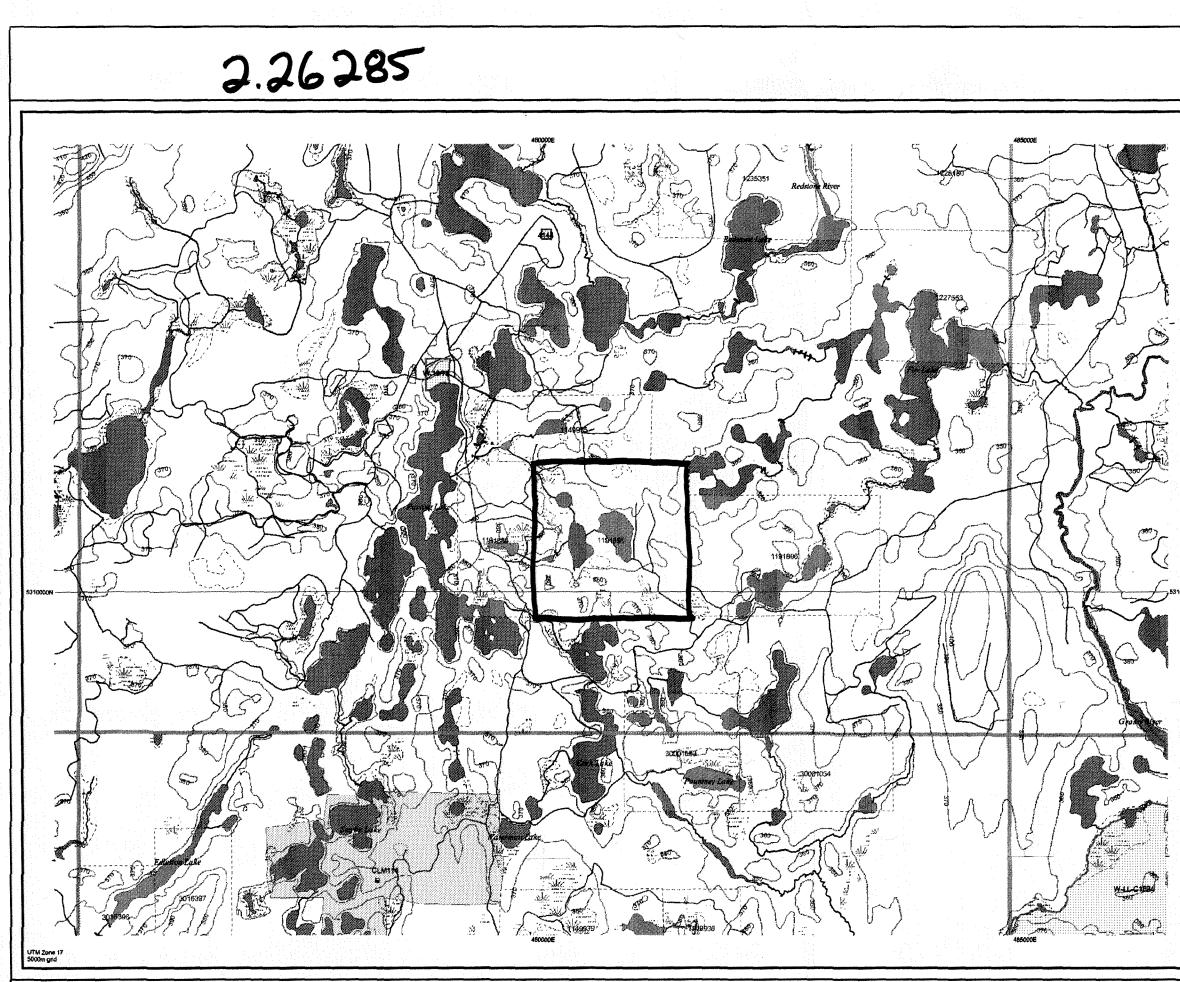

Cc: Resident Geologist

John Douglas Bryant (Claim Holder)

James Ernest Croxall (Claim Holder) Assessment File Library

John Douglas Bryant (Assessment Office)

Matti Kangas (Claim Holder)

Those wishing to stake mining claims should consult with the Provincial Mining Recorders' Office of the Ministry of Northern Development and Mines for additional information on the status of the lands shown hereon. This map is not intended for navigational, survey, or land title determination purposes as the information shown on this map is compiled from various sources. Completeness and accuracy are not guaranteed. Additional information may also be obtained through the local Land Titles or Registry Office, or the Ministry of Natural Resources.

General Information and Limitations

Contact Information: Toll Free Map Datum: NAD 83 Provincial Mining Recorders' Office Tol: 1 (888) 415-9845 ext 5788bjection: UTM (6 degree) Willed Groen Miller Centre 933 Ramsey Lake Road Fax: 1 (877) 670-1444 Topographic Data Source: Land Information Ontario Sudbury ON P3E 685 Home Page: www.mndm.gov.on.ca/MNDM/MINES/LAND8/mtsmnpge.htm

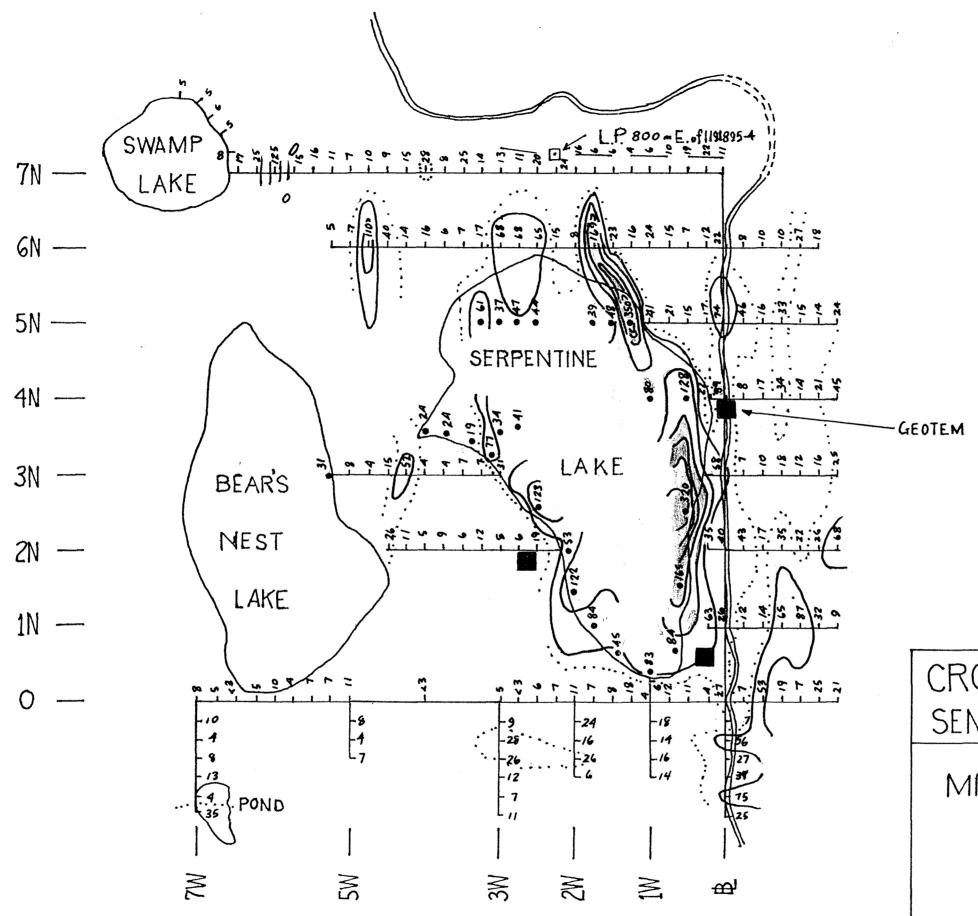

This map may not show unregistered land tenure and interests in land including certain patents, leases, easements, right of ways, flooding rights, licences, or other forms of disposition of rights and interest from the Crown. Also certain land tenure and land uses that restrict or prohibit free entry to stake mining claims may not be illustrated.

The information shown is derived from digital data available in the Provincial Mining Recorders' Office at the time of downloading from the Ministry of Northern Development and Mines web site
