Lithology Identification

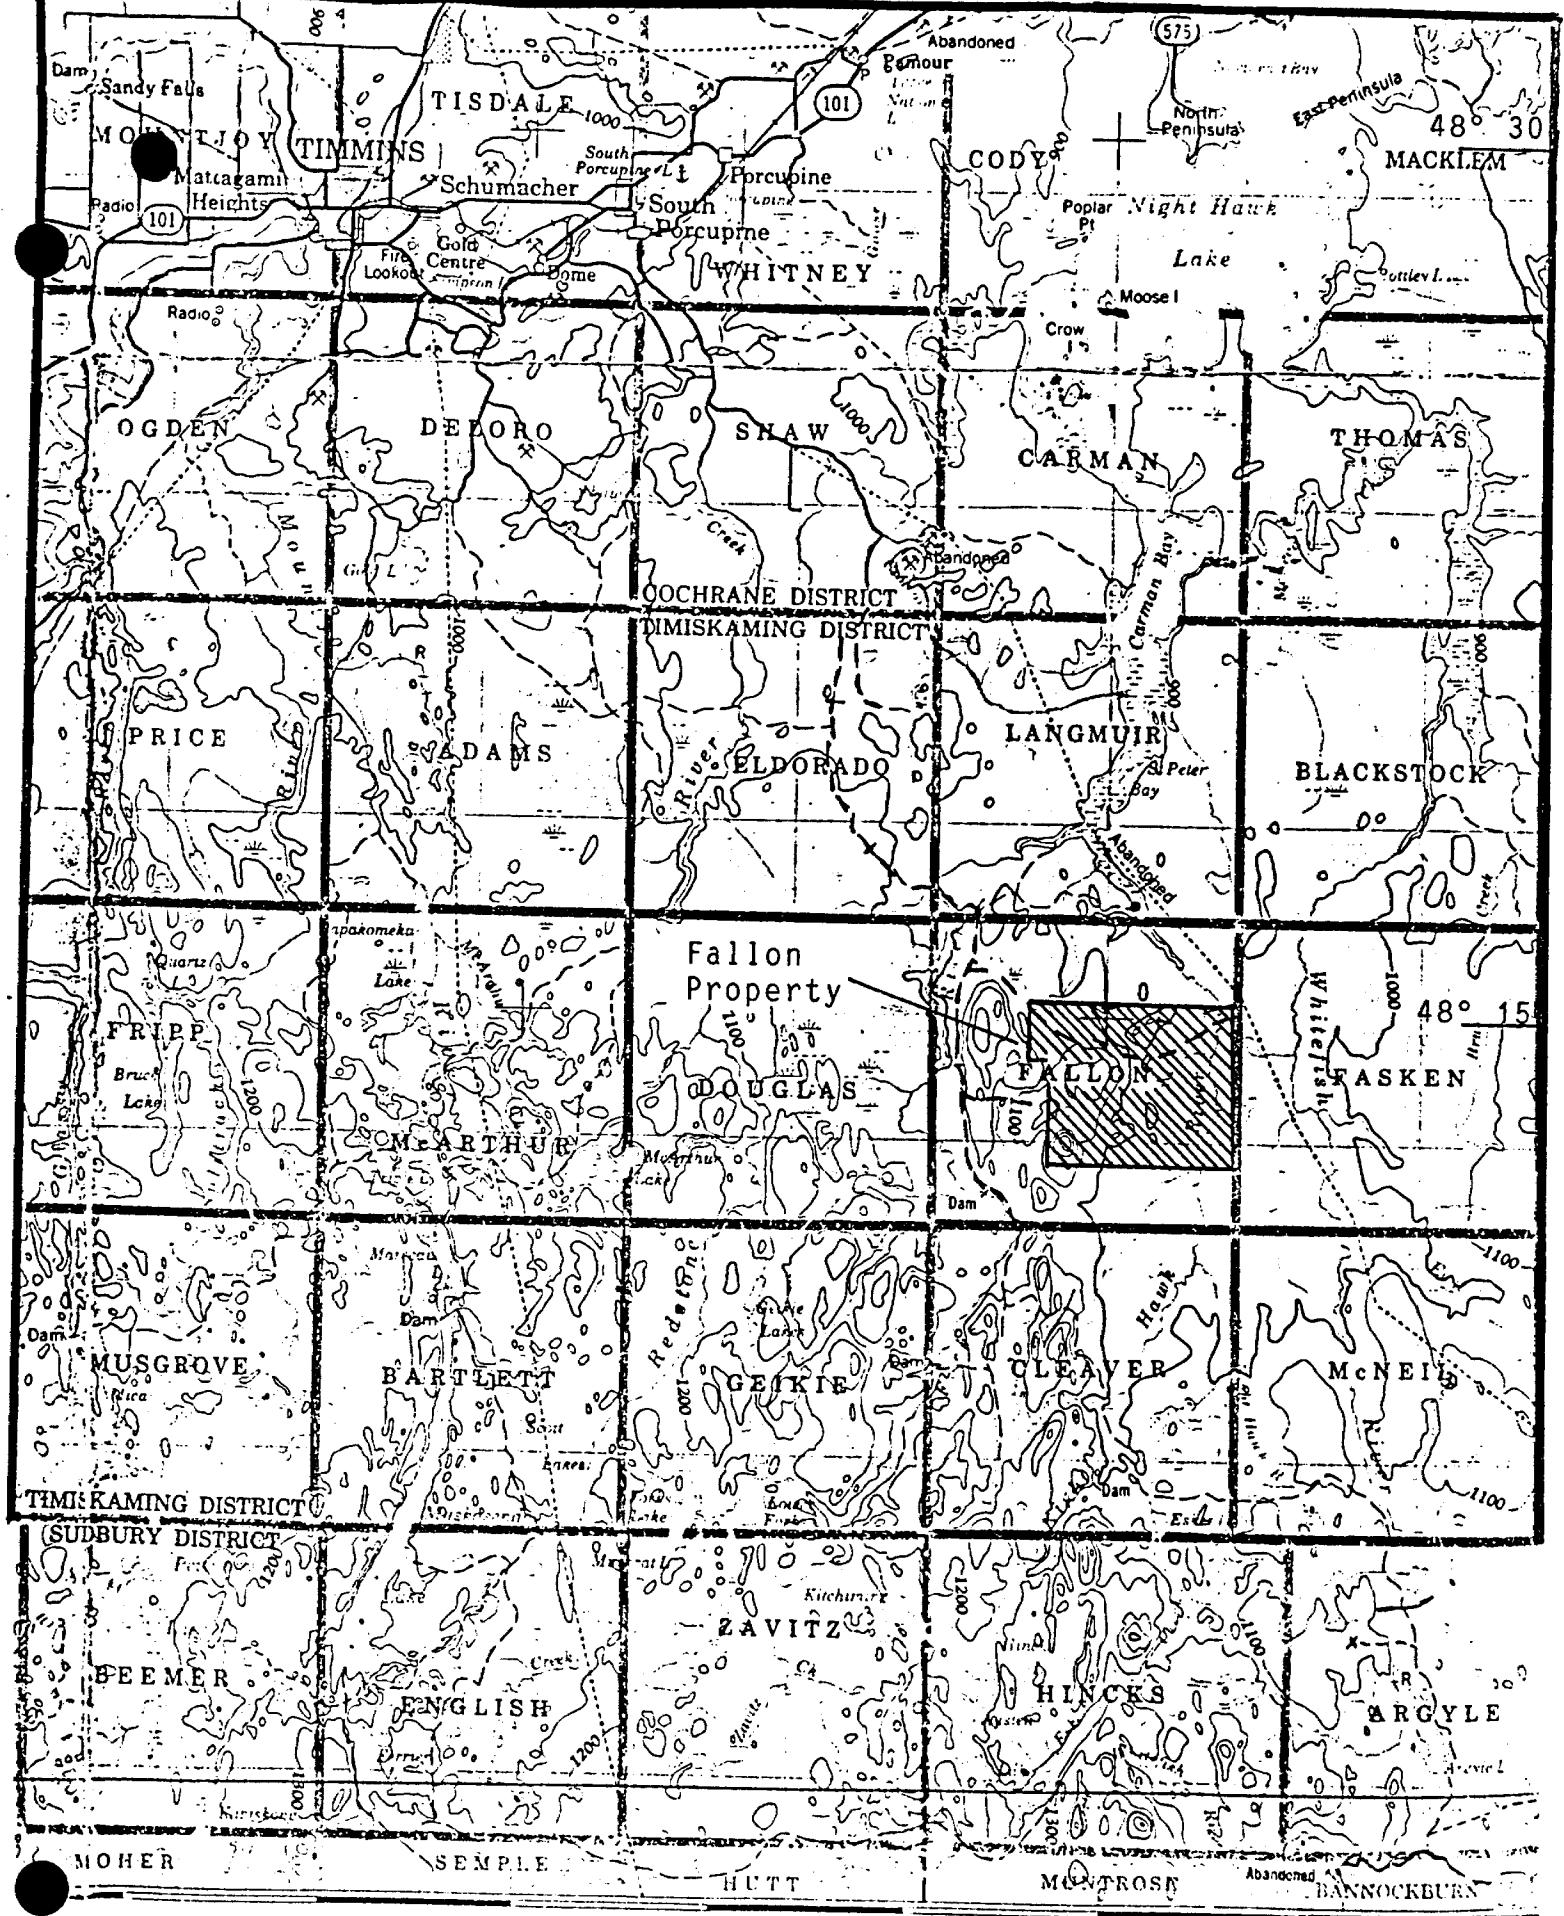

## Introduction and Summary of Results

This report describes the partial results of a basal till sampling program performed by R. Cormier and Associates Ltd. between June 2-12, 1985, inclusive, on the Fallon South Grid. The work was undertaken to evaluate and, if possible, detect the causative sources of two V.L.F. electromagnetic conductors that had been outlined in a geophysical survey conducted in 1984. Information was also obtained about the bedrock geology and overburden in the vicinity of the conductors. The property is located in Fallon Township, approximately 38 kilometers southwest of the city of Timmins. Mr. David J. Meunier of South Porcupine, Ontario is the owner of the claims.

R. Cormier and Associates Ltd. utilized a pionjar, precussion drill to obtain till samples from the bedrock-overburden interface. This report describes the results from 18 holes which were drilled on two lines over two different conductors. Microscopic, mineralogical and lithological identifications were respectively performed on the heavy mineral separates of the -5 to +250 mesh and the entire +5 mesh size fractions. The -5 to +250 mesh identifications were done by C.F. Gleeson and Associates Ltd. and the +5 mesh identifications were done by the author of this report. All of the size fraction, heavy mineral and magnetic separations were completed by R. Cormier and Associates Ltd. The work applied for assessment credits was done by R. Cormier and Associates Ltd. and includes the cost of drilling and sample preparation.

Basal till was recovered in 72% of the holes from an average depth of 7.9 meters. The average cost per hole was \$172.10. Most drill logs indicated an organic layer normally overlying clay or silt followed by coarse sand and gravel and basal till horizons. Several shallow holes failed to intersect the silt-clay soil horizon. No explanations for the conductors were determined. Lithological identifications of samples collected on line 2E indicate the samples are taken over, or up-ice, from intermediate tuffs and flows and minor monzonite, mafic volcanics and Huronian sediments. On line 4E mafic flows predominate with minor amounts of intermediate flows and tuffs, monzonite, diabase and felsic flow also being sampled. Volcanic clasts are generally weakly chlorite ± carbonate altered, are unmineralized or host trace disseminated pyrite and are undeformed to weakly schistose. Heavy mineral identifications indicate that samples 5066 and 5067 are moderately altered. Samples 5060 to 5065 contain relatively high pyrite contents of 1-3 percent.

Location Map-Fallon Property

Scale 1:250,000

5 0 5 10 15  
KILOMETERS

Figure 2.

### Location and Access

The property is centered approximately 38 kilometers southwest of Timmins at latitude 48° 13' north and longitude 81° 00' west. Figures 1 and 2 illustrates the properties location at scales of 1:1,600,000 and 1:250,000 respectively.

Gravel road access is available to the north of the grid commencing at Connaught Hill south of South Porcupine. The Langmuir Mine road is followed from Connaught Hill for a distance of 15.2 kilometers until the junction with Night Hawk Timber Co. Ltd's private access road is met. The access road is followed south and then west for another 20 kilometers until the grid is reached. Alternatively, the southwest of the grid may be accessed by following a different succession of Night Hawk Timber Co. Ltd's access roads for 30 kilometers until the junction with a four wheel drive bush road is met. The bush road is followed for 6 kilometers, to within several hundred meters of the grid. Additionally water access may be obtained to the east of the property along the Night Hawk River, which is in turn road accessible to a point one kilometer north of the property.

### Physiography and Vegetation

Elevation variances of between 10-20 meters occur where areas of outcrop rise abruptly from low lying, flat swampy regions. In part, the outcrop areas are thought to be fault bounded, having steep sided scarps at their edges.

Outcrop areas are covered by spruce, pine, balsam and occasionally poplar forest cover. Intervening swampy regions are overlain by spruce, balsam, alder and muskeg. Creeks, draining in a dominantly easterly direction, are present in the southeast, southwest and northcentral portions of the Fallon South Grid.

Outcrop exposure is 10%-15%, being primarily confined to the south-central, west-central and northeast portions of the mapped region. Other areas are overlain by substantial thicknesses of glacial drift.

#### Property Description

All the claims covered in this report are situated in Fallon Township, Porcupine Mining Division, District of Timiskaming. Claims on which assessment credit are being applied for include; P-792533-P-792536, P-792539, P-783572-P-783574, and P-663472-P-663474. Claims upon which work was performed and which are contiguous with the above claims include; P-663470, P-641793, and P-641734.

#### Survey Procedure

Basal till sampling was conducted between June 2-12, 1985, by a two man crew utilizing a pionjar drill. The pionjar drill is a portable precussion drill that obtains a single overburden sample from each hole, over a 20 centimeter long interval, immediately above the bedrock-overburden interface.

Either 5 or 13 holes were drilled at 12.5 and 25.0 meter intervals, along  $115^{\circ}$  trending metric grid lines, across the conductors. Two lines of holes were drilled across two separate conductors. In total 18 holes having an aggregate length of 142.0 meters were completed. Weights of recovered samples ranged from 113.9 to 325.5 grams, having an average of 209.7 grams. Drill logs, summarizing the types of overburden encountered, were completed simultaneously with the drilling, by the drill crew personnel.

Sample preparation was done by R. Cormier and Associates Ltd. Initially the samples were screened into +5, -5 to +250 and -250 mesh size fractions. The -5 to +250 mesh fraction was then subjected to heavy liquid separations using tetrabrom-aform ( $2.96 \text{ gm/cm}^3$ ) and methylene iodide ( $3.2 \text{ gm/cm}^3$ ). Grains having specific gravities of between  $2.96$  to  $3.2 \text{ gm/cm}^3$  and greater than  $3.2 \text{ gm/cm}^3$  were then subjected to magnetic separations. Microscopic examination of the magnetic and non magnetic portions of the -5 to +250 mesh size fraction, with a specific gravity of greater than  $3.2 \text{ gm/cm}^3$ , was completed by C.F. Gleeson and Associates Limited. The +5 mesh size fraction underwent binocular microscopic examination by the author of this report.

#### Property Geology

The description of the property's geology is taken from the results of a geological mapping survey completed in

the summer of 1985, at a 1:5000 scale, on the Fallon South Grid for Mr. David J. Meunier. Mapping was partially completed by the author of this report.

### Lithology

Areas where sampling was undertaken are dominantly underlain by Archean aged calc-alkaline intermediate to mafic metavolcanic flows and pyroclastics that are intercalated on a scale of tens to hundreds of meters. Rarely occurring as thin units associated with the intermediate tuffs are felsic metavolcanic tuffs. Intruding and altering the metavolcanics are a large number of Archean monzonitic plugs and dikes. Minor, thin north-south trending mafic dikes intrude the monzonite intrusives and metavolcanics. West of the sampled lines is a large outlier of Proterozoic, Cobalt Group, Huronian, relatively flat lying sediments. Several hundred meters west of line 2E there is a thick NNE trending Proterozoic diabase dike.

Pyroclastics are mainly intermediate in composition and include tuff, lapilli tuff and agglomerate varieties. Normally they are grey to green in colour, hosting subrounded to subangular white to pink coloured fragments in a fine grained matrix. On occasion the pyroclastics display a well developed banding. Agglomerates and lapilli tuffs could not be differentiated from the tuffs, by microscopic examination.

Flows are normally mafic in composition, and green to black in colour. They occur predominantly as fine grained massive and less commonly as porphyritic varieties. Porphyritic flows host up to 30%, 0.5mm - 1.0mm diameter plagioclase phenocrysts in a fine grained matrix. The flows are occasionally magnetic.

Porphyritic monzonites are pink to grey in colour and host up to 40%, 0.5mm - 7.0mm diameter, feldspar phenocrysts in a medium grained matrix. Most commonly they contain no quartz and hornblende ± pyroxene is their only mafic constituent. Less frequently the porphyritic monzonites contain up to 10% quartz and biotite is the primary mafic mineral. Equigranular varieties of the monzonite are locally present.

Mafic dikes are dark green to black, fine grained units having thicknesses not exceeding 2 meters.

Felsic tuffs are grey, extremely hard, finely banded to massive units that are very fine grained. The tuffs have thicknesses not exceeding 10 meters in the sampled area. North of the sampled area, felsic tuff-lapilli tuff units attain thicknesses of up to 60 meters.

Huronian sediments occur as buff, maroon, grey, brown and green coloured siltstones, argillites, sandstones, greywackes and conglomerates. They are devoid of alteration and lack indicators of deformation.

The Proterozoic diabase is a grey to green coloured 50-100 meter thick unit that is medium grained and only weakly to non magnetic.

#### Quaternary Geology

Ninety five percent of the grid area is overlain by unconsolidated Quaternary deposits. Glaciolacustrine clay and silt are the dominant deposit type, covering approximately 70% of the area (Lee 1979) Subordinate peat and organic terrain overlies the glaciolacustrine sediments. Outcrop areas on the southwest grid region are covered by C horizon soil or a thin veneer of till. Basal till and/or gravel was found to have a thickness of 0.2-4.4 meters. Overburden in the sampled holes had an average depth of 7.9 meters. Glacial material is believed to have been transported from north to south (Pyke, 1970)

#### Structural Geology

Bedding and flow strike directions vary from  $0^\circ$ - $150^\circ$  with steep north and south dips. Overall the units have an east-west strike direction. The metavolcanic units have been subjected to an early period of E.S.E. shearing that is associated with small scale axial planar folding. A second, later, period of deformation involves faulting along north-south trends in a dominantly left lateral sense. Drag folding of the metavolcanic units is prevalent adjacent to the north-south faults, causing the

volcanic units to partially align themselves with the faults. The north-south trending faults were at one time extensional features, being infilled by the mafic dikes and barren quartz veins.

#### Economic Geology

Quartz-epidote-feldspar ± carbonate - pyrite alteration occurs in discrete zones and is related to the E.S.E. period of shearing. The intensity of alteration and pyrite mineralization increases towards the monzonite stocks and dikes. Possibly the shearing event is synchronous with the intrusion of the monzonite. Minor barren quartz veins and specular hematite veins are associated with weak alteration in and along north-south trending fracture/fault zones. No instances of economic mineralization are known in the immediate area or were observed on the property.

#### Results of Till Identification

Drill logs, detailing the types of overburden encountered, were completed by drill contractor personnel while drilling was underway. These logs are presented in appendix I, at the back of the report. Most holes initially encountered 0.1 to 0.2 meters of organic material followed by a variable thickness of either clay, or silt followed by sand and gravel horizons. Basal till was normally encountered 1.0 to 0.2 meters above the bedrock-overburden interface. On two occasions the holes ended in sand

or gravel with no till being recovered. C horizon soil was sampled at one location. The depth of overburden varied from 0.2 to 16.0 meters having an average of 7.9 meters.

#### Results of +5 Mesh Clast Identification

Major and minor clast lithology types, along with overburden depth, number of clasts and sample type are presented on the map in the back pocket of this report. Clast lithology identifications failed to determine the causes of the conductors. Samples taken from line 2E indicate that intermediate tuffs and flows are the major lithology type underlying or up-ice from the sample sites. Lesser amounts of porphyritic and equigranular monzonite, mafic volcanic flow, granites, vein quartz, diabase, Huronian sediments and felsic tuffs are also present. On line 4E mafic volcanic flows are the major clast type with lesser amounts of intermediate tuffs, monzonites, diabases, intermediate flows, felsic volcanics and Huronian sediments being observed. Mafic-intermediate volcanics are invariably chlorite altered and have occasionally undergone carbonate, silica and epidote alteration. Trace to one percent pyrite was observed as fine disseminations hosted in metavolcanic flows in samples 5060, 5068, and 5069. Several clasts are weakly to moderately schistose. Clast identification confirms earlier bedrock mapping which indicated the presence of intercalated intermediate flows and tuffs intruded by porphyritic monzonite on line 2E, where outcrop is proximal

to the sample locations. On line 4E, where outcrop is absent, the presence of magnetic mafic volcanic clasts may suggest a iron rich tholeiitic sequence of volcanic flows on the south of the Fallon South Grid.

Heavy Mineral (+3.2gm/cm<sup>3</sup>), -5 to +250 Mesh Identifications

Results of the heavy mineral identifications are presented in appendix II. No explanation for the conductors was noted. Minerals occurring in amounts consistently greater than 5% and listed in order of abundance are; pyroxene, epidote, magnetite, amphibole, and garnet. Minerals occurring in minor amounts include; apatite, biotite, chromite, ilmenite, hematite, leucoxene, sphene, tourmaline, pyrite and zircon. Samples 5066 and 5067 are notable because of the altered nature of their mineral grains. One to three percent pyrite is present in samples 5060 to 5067 which compares to trace amounts in the other samples. Higher than average epidote values in samples 5060-5069 may be indicative of shear related alteration that is also associated with the increased pyrite content of most of these samples. Several of the +5 mesh clasts, over this sample interval, are epidote-carbonate altered.

Total Miles of line Cut

## Name and Address of Author (of Geo-Technical report)

Paul Miller, 448 Eglinton Ave W., Toronto.

## Credits Requested per Each Claim in Columns at right

Special Provisions	Geophysical	Days per Claim
For first survey: Enter 40 days. (This includes line cutting)	- Electromagnetic	
	- Magnetometer	
	- Radiometric	
	- Other	
For each additional survey: using the same grid: Enter 20 days (for each)	Geological	
	Geochemical	

Man Days	Geophysical	Days per Claim
Complete reverse side and enter total(s) here	- Electromagnetic	
	- Magnetometer	
	- Radiometric	
	- Other	
	Geological	
	Geochemical	

Airborne Credits	Days per Claim
Note: Special provisions credits do not apply to Airborne Surveys.	
	Electromagnetic
	Magnetometer
	Radiometric

## Expenditures (excludes power stripping)

Type of Work Performed
Basal Till Sampling Survey
P663470; P663467; P654193
P663907; P663910

## Calculation of Expenditure Days Credits

Total Expenditures	Total Days Credits
\$ 2070	÷ 15 = 138

## Instructions

Total Days Credits may be apportioned at the claim holder's choice. Enter number of days credits per claim selected in columns at right.

Date	Recorded Holder or Agent (Signature)
Nov 1/85	Brian Madill

## Certification Verifying Report of Work

I hereby certify that I have a personal and intimate knowledge of the facts set forth in the Report of Work annexed hereto, having performed the work or witnessed same during and/or after its completion and the annexed report is true.

## Name and Postal Address of Person Certifying

Dear Sir:

RE: Assaying submitted under Section 77(19)  
of the Mining Act RSO 1980, on Mining  
Claims P 641734, et al, in Fallon Township

---

The enclosed statement of assessment work credits  
for assaying expenditures has been approved as of  
the above date.

Please inform the recorded holder of these mining  
claims and so indicate on your records.

Yours sincerely,

S.E. Yundt, Director  
Land Management Branch

David J. Meunier  
403 Dome Street  
South Porcupine, Ontario  
PON 1H0

Dear Sir:

RE: Mining Claims P 792533, et al,  
in the Township of Fallon

---

I have not received the data and maps (in duplicate)  
for the Basal Till Survey on the above-mentioned claims.

As the assessment "Report of Work" was recorded by the  
Mining Recorder on November 5, 1985 the 60 day period  
allowed by Section 77 of the Mining Act for the submission  
of the technical reports and maps to this office will  
expire on January 4, 1986.

If the material is not submitted to this office by January 4,  
1986 I will have no alternative but to instruct the Mining  
Recorder to delete the work credits from the claim record  
sheets.

For further information, please contact Mr. Arthur Barr at  
(416)965-4888.

Yours sincerely,

S.E. Yundt

Dear Mr. Barr;

Enclosed please find 2 copies  
of a report entitled: Basal Till Sampling  
on the Fallon South Grid, Fallon Twp.  
We have previously filed a Report of  
Work (Expenditure Credits for Assessment)  
relating to this, with the Timmins  
Mining Recorder.

Trusting all is in order.
