1.0 SUMMARY

The Cleyo Resources-Cleaver Township property is located in an area which has only seen sporadic exploration since the early 1900's. In the spring of 1986, Mr. Cleo Clement in the company of the property vendor, undertook a site examination. From this property visit several grab samples were collected, from which highly anomalous assay results (0.10-0.20 range) were received. These encouraging results, prompted Mr. Clement on behalf of Cleyo Resources Inc. to approach the firm of David R. Bell Geological Services Inc. with a request that a property visit be made and introductory report be prepared. It was as a result of this visit and report that the recommended exploration program was initiated. In light of the late start to the program and the early arrival of winter, the proposed program could not be completed and as a result, only the mapping and IP surveys were finished.

A minor amount of stripping was completed late in the program, with these new exposures to be examined during the recommended program.

The property was found to be underlain by a series of interbedded intermediate to mafic flows. These flows show a variety of flow features, strike northeast-southwest, dip steeply to the south, and vary from non-magnetic to highly magnetic.

During the mapping program two auriferous zones were located. One of these showings is located in the same outcrop as the "Main Showing" that had been previously visited by the author. Examination of this showing, which was limited by a lack of good weather, found a highly brecciated, altered and mineralized rock that gave assays of up to 0.088 oz Au/ton. The second gold showing, also the site of some earlier trenching, was hosted by intermediate to mafic volcanics that have

been silicified and mineralized. Assays from this zone of up to 267 ppb Au were received. The results from both zones are found to be very encouraging in light of the limited work that has been completed. These zones also show a correlation with either magnetometer, VLF-EM, or IP anomalies.

Due to these promising results, a three phase exploration program totalling $263,000.00 has been recommended. The initiation of this third phase will be contingent upon the receipt of encouraging results from the first two phases.

2.0 INTRODUCTION

In October of 1986 the firm of David R. Bell Geological Services Inc. was contracted to initiate a exploratory program. This program was recommended as a result of a property visit made during May of 1986 and a search of all pertinent company and government information. The McNeil-Cleaver Township area is the location of several gold showings, but at the time has received only sporadic exploration activity. One showing in McNeil Township is hosted by mineralized rock that contains visible gold.

3.0 LOCATION AND ACCESS (see Figure 1 and 2)

The Cleyo Resources property is located 29 miles south-east of the city of Timmins in Cleaver Township, Larder Lake Mining Division, in the District of Timiskaming, Ontario. This claim group is found in the west-central portion of the township at 48.13 degrees north latitude and 81.47 degrees east longitude.

Access to Cleaver Township is gained by travelling approximately 30 miles on the Langmuir Road, an all weather lumber road that runs southwest from the town of South Porcupine. Once in the vicinity of the property, three routes can be used to access the northwest, north-central and south-central portions of the claim group. These access routes can be travelled using a two-wheel drive vehicle, but spring and fall weather may necessitate a vehicle with four-wheel drive capabilities.

4.0 PROPERTY AND OWNERSHIP (see Figure 3)

The Cleyo Resources, Cleaver Township property is composed of 27 contiguous unpatented mining claims (see Table 1) which are held in trust by Mr. Cleo Clement of Timmins, Ontario.

The property was optioned from Mr. William Dellaire of Timmins, Ontario, in January of 1986 and at that time consisted of only 23 claims. After reviewing the results of previous geophysical surveys and noting the location of the primary showing, the author recommended that an additional four claims should be staked. The acquisition of these claims would give complete coverage of this principle showing and any possible strike extension. These claims were subsequently staked in April of 1986, bringing the total number of claims to the present twenty-seven.

At the present time the 23 original claims (various recording dates in 1983) are under extension until Dec. 31, 1986, and require 40 days of assessment credits. The filing of this report for linecutting and geological survey credits will fulfill the necessary requirements to keep all claims in good standing until their respective anniversary or next filing dates in 1987 and 1988.

5.0 PHYSIOGRAPHY AND CLIMATE (see Figure 4)

The Cleyo property is situated in an area of mixed topography. A general pattern of low relief dominates this region with the elevation ranging from 1050 to 1150 feet above sea level. In the west half of Cleaver Township an area of moderate to high relief is present, here the terrain attains a maximum of 1500 feet above sea level. This north trending area of higher ground is probably caused by the Middle-Precambrian Sediments of the Cobalt Group.

The claim group is drained by numerous lakes and rivers of the Nighthawk River system. This river system flows north and eventually drains into Nighthawk Lake.

Vegetation and overburden are typical of Northern Ontario. Sand, gravel and moderate to well developed "B" soil horizons are found in the higher better drained areas of the claim group, where poplar, birch, spruce and local stands of balsam fir are located. The lower lying areas of this property are covered by clay and water rich organic soils. It is in these areas that stands of cedar, spruce and alder dominate. In all areas, numerous types of mosses and grasses are present.

As a result of the Northern Ontario Engineering Geology Terrain Studies that were completed by the Ministry of Natural Resources, several sources of sand and gravel were located in this region (see Figure 5). In fact one such source is located on the Cleyo property. This source is a north trending esker that is found in the southeastern portion of the property. The Ministry has estimated that these local sources have a medium to high potential for coarse aggregate. These coarse aggregates will be valuable if the construction of access roads or mining facilities is ever initiated.

The climate of the area is characterized by hot, humid summers and long winters. An abundance of snowfall, and extreme cold are common during the winter months.

6.0 POWER AND WATER

The power requirements for any early stages of exploration or development would have to be supplied by diesel generators. Although a major north-south power line is located 12 miles due east of the Cleaver Township property, it may be more cost effective to construct a power line from Matachewan, which is located approximately 21 miles to the southeast. This is due to the fact that the appropriate sub-stations are already present and therefore construction costs may be minimized.

An abundant water supply for any exploration or early development programs is present within the boundaries of this property. If greater quantities of water are required, then accessing the larger lakes to the southwest, or Nighthawk Lake to the north, should meet any foreseeable requirements.

7.0 ANCILLARY SERVICES

All goods or services that would be needed for any of the various exploration or mining phases could be acquired from the city of Timmins.

8.0 PREVIOUS WORK

Prospecting and exploration for gold had begun in the Matachewan district in as early as 1909, but the attention of the prospectors soon swung to silver, as the discoveries near Gowganda and Elk Lake were made. When the news of a major gold discovery within the Porcupine Camp (1909) became wide spread, the Matachewan area saw a renewed interest in gold exploration. Numerous occurrences were uncovered in the townships of Powell, Cairo, Alma and Baden. As well as private exploration, several geological and topographical surveys were conducted by government agencies during the 1910's, especially in the vicinity of the then, most current gold discoveries.

It was not until 1923 that any gold discoveries were made in the Cleaver-McNeil Townships area. Three Indians named Isador, Micmack and Tom Fox uncovered a gold showing in the south-central part of McNeil Township. This discovery led to the uncovering of several more occurrences in McNeil Township and eventually, Mr. Dan O'Connor located two gold showings in the west-central section of Cleaver Township. Apparently nothing of significance ever came of these discoveries.

The Cleaver-McNeil area received very little attention during the intervening years between the 1920's and the 1950's. When exploration activities again increased, the bulk of the work was concentrated in the west half of Cleaver and the eastern part of McNeil Township. The companies and their respective exploration activities as conducted in Cleaver Township are listed in Table 2.

The only work that has been recorded for the vicinity of the present Cleyo Resources property, has all been completed since 1974. Stripping and trenching have been completed by J. Boissoneault and R. Rousseau on ground that is now covered by claims L724470 and L724474. Linecutting, magnetometer and VLF-EM surveys were completed in early 1984 under a previous option agreement. The assessment credits for this work are still valid and in fact are being used to keep the claims in good standing. These surveys have outlined several areas of interest that have as yet not been examined.

9.0 REGIONAL GEOLOGY AND STRUCTURE (see Figure 6)

9.1 Regional Geology

Cleaver Township, and subsequently the Cleyo Resources property, is underlain by rocks that are entirely Precambrian age. The majority of the bedrock belongs to the Abitibi Greenstone Belt, which being Early Precambrian or Archean in age, is a tectonically differentiated portion of the Superior Province

of the Canadian Shield. Rocks of Middle and Late Precambrian age are respectively represented by Cobalt Group sediments and minor intrusions of diabase.

The Abitibi Greenstone Belt, in the vicinity of Cleaver Township, is composed of variably metamorphosed igneous, sedimentary and volcanically derived rocks (Pyke, 1978).

9.11 Metavolcanic Rocks

The metavolcanic rocks of this area are represented by at least two cycles of volcanism. The ultramafic rocks occupy the lowest position of each cycle, while the mafic, intermediate and felsic rock types sit in respectively higher stratigraphic locations. The lowest of these two cycles, trends in a north-south direction through Fripp, McArthur, Bartlett and English Townships. The dominant, or upper cycle, shows an east-west, as opposed to the expected northerly trend. This may in part be the result of the intrusion of the Geikie Pluton, even though the regional magnetometer survey suggests that this east-west trend, is more typical of the Cleaver-McNeil area.

The ultramafic metavolcanic rock types are by far the most sparcely distributed. Massive, polysutured and spinifex textured flows are the most common of these rocks, while pyroclastic units are found locally.

The most dominant of all rock types in this area are the mafic to intermediate metavolcanics. Lithological varieties included within these units are the massive, pillowed and variolitic flows. In conjunction with these flows, pyroclastic rocks in the form of tuff, lapilli tuff and volcanic breccia are found.

The felsic metavolcanic rocks are represented by massive and pillowed flows as well as the aforementioned types of pyroclastic rocks. Centers of felsic volcanism are located in the area of Douglas-Fallon-Fasken and McArthur-Bartlett-English-Hutt Townships.

9.12 Metasediments

Metasediments apparently, form only a very small portion of this section of the Abitibi Greenstone Belt, comprising no more than five percent of the exposed area. Where noted by previous workers, the Early Precambrian metasediments are found to be associated with the intermediate to felsic volcanics (Pyke, 1978). Middle Precambrian metasediments are represented by the Cobalt Group, which in this area is composed of arkoses, greywackes and argillites. These rocks lie in a thin band that runs in a north-south direction through Montrose, Hincks, Cleaver and Fallon Townships.

9.13 Intrusives

The intrusive rocks which are present in this area, range in chemical composition from felsic to untramafic.

The major felsic intrusions, such as the Peterlong Lake Complex, and the Adams and Geikie Plutons, are composed of feldspar and quartz porphyries, trondhjemites, granodiorites, quartz diorites and diorites. Smaller intrusions of the same relative compositions are also present in this area along with intrusions of syenitic composition such as the Fallon Stock.

A large zone of mafic to ultramafic intrusions, is found in the central portion of the lower most volcanic cycle, sitting at the contact between the mafic and the intermediate to felsic volcanics. There appears to be a genetic relationship between these intrusive bodies and the more "felsic" rock types, as is noted by their close spatial association in the Bartlett-McArthur and Zavitz-Hutt Townships area. These intrusives may be composite bodies of the following, gabbro, gabbroic anorthosite, pyroxenite, serpentinized peridotite, and quartz gabbro. Other gabbro intrusions have been noted in McNeil Township. As a result of the

linear magnetic trends in the Cleaver-McNeil area and the magnetic anomalies in Cleaver Township it is possible that other mafic stocks or plugs may be located within the vicinity of the project area.

9.2 Regional Structure

As previously noted, the volcanic rocks of this area show two major trends. The lower cycle trends north-south, generally dips to the east at 65 to 80 degrees (local variations are present), while tops face east showing that these units have not been overturned. Except for major north-south faults these rocks do not appear to have been severely deformed, at least folding on a large scale is not evident.

The upper volcanic cycle, has undergone deformation, by both folding and faulting. Numerous anticlinal and synclinal structures are located within Douglas, Zavitz and Hutt Townships. These are crosscut and offset by the northerly and northwesterly trending faults that transect this area.

Details as to the structural make-up of the Cleaver-McNeil area are limited due to the lack of any detailed exploration by either government or private industry.

10.0 PROPERTY GEOLOGY AND STRUCTURE

During the course of the mapping program approximately 200 bedrock outcroppings were examined for geological, mineralogical and structural information. Although this sounds like a substantial amount of exposure, it in fact represents only about 10-15% of the entire property. In so far as this is the situation, geophysical (magnetometer and VLF-EM) data from previous surveys was used as an interpretational aid to develop a geological framework from which further exploration could be recommended.

10.1 Property Geology (see Map 6436-86-4-1)

The Cleyo Resources-Cleaver Township property is found to be underlain by rocks that are of early Precambrian age. Through field examinations the following rock types have been recognized; magnetic and non-magnetic mafic flows, intermediate to mafic flows and minor felsic intrusions.

10.1.1 Mafic Flows

By far the most dominant rock types that were seen during the mapping program, are the mafic flows. Visual classifications, based upon colour and mode of occurrence, suggest that these rocks are of basaltic composition. Major and trace element geochemical analysis has for the most part confirmed this assumption.

The geochemically determined rock types were dominantly found to be of the tholeiitic chemical trend, while being of either basaltic or "iron-rich" basaltic composition. A few exceptions were noted. One exposure located at L8W at 0+30N is still of the tholeiitic chemical trend but is of andesitic composition. This is not uncommon by virtue of the fact that the exposure sits near a flow top environment and may only be an isolated occurrence. The other exception, located on L16W at 28+50N and while being of basaltic composition is found to be of the calc-alkalic chemical trend. This analysis matches with the magnetometer survey which shows a trend of lower susceptibility in the area.

These basalts are found as both massive and pillowed flows, while well developed sections of flow top breccia are locally noted. The massive flows being green to dark green in colour range from aphanitic to coarse grained in texture, with the fine to very fine grained varieties being dominant. It is only within the coarse grained sections that the mineraology can be discerned, and then only the plagioclase feldspar from the mafic (pyroxene-amphibole) component. Well developed sections of pillowed flows are seen to top the massive sections, with

individual pillows attaining dimensions of at least four feet in length and three feet in width. Locally the pillows may contain well developed vesicules which can be used for tops determination. The selvages are seen to contain both variolitic growths and hyaloclastite (glass shards). The flow top breccia are characterized by angular to sub-rounded flow brecciated fragments in a chloritic matrix, which may contain both variolites and hyaloclastite.

All varieties of basalts, whether massive, pillowed or flow breccias were found in both magnetic and non-magnetic phases. The magnetic and some non-magnetic sections have been chemically defined as iron-rich tholeiites, while the non-magnetic sections are represented by iron-rich tholeiitic basalts, tholeiitic andesites and basalts, and calc-alkalic basalts.

10.1.2 Intermediate to Mafic Tuff

Only one exposure of tuffaceous rock was round during the course of the mapping program. This outcrop, located on L16W at 17+40N is composed of a grey to grey-green rock, which weathers to a buff colour and shows definite, clastic features when examined closely. The rock is composed of approximately equal proportions of rounded to sub-rounded quartz and feldspar clasts, that are supported by a chlorite-muscovite-carbonate rich matrix. Both orthoclase (pink) and plagioclase (zoned) are found to represent the feldspar minerals in the portion of the clasts.

10.1.3 Intermediate to Felsic Flows

Exposures of the intermediate to mafic flows have been located in the south-central section of the property. These exposures all appear to be part of the same northeast trending unit. This horizon is coincident with a zone of low

magnetic susceptibility, as is expected from visual examination. These rocks are characterized by their pale grey to green and locally grey green colour, dominantly aphanitic texture and lack of magnetic response.

Geochemical analysis of these rocks has returned rhyolitic compositions of both the calc-alkalic and tholeiitic chemical trends. This is in agreement with the gross visual aspects of these rock units.

An exposure of these flows is located at 6+00W and 7+20S, these rocks are found to contain up to 10% fine grained disseminated pyrite, and are extremely hard. At this time it is unknown whether these features are of primary origin or are a result of an alteration process. Samples from this outcrop have been collected and analyzed, the results are discussed in the mineralization and alteration section.

10.1.4 Felsic Intrusions

Two felsic intrusive exposures were located as a result of the geological mapping. The first of these, located on L8W at 0+80N, is a rock of intermediate composition, that shows a dominantly grey colour with green to dark green mafic clots, and has an aphanitic texture. The exact nature of the mineralogy is undiscernable due to the microscopic grain size.

The second exposure is located at 15+00W-5+85N. This rock is of syenitic composition. This classification is based on colour alone, as the fine grained nature of the rock does not allow for mineralogical determinations. The pink colour represents the dominant orthoclase feldspar, while the black mineral (3-5%) represents the mafic component.

10.2 Property Structure

The Cleyo claim block is underlain by a northeast-southwest trending series of intermediate to mafic metavolcanics, with isolated felsic intrusions. Direction or tops determination can be made due to the well developed and exposed flow structures. These features or structures, are found in the form of flow top breccia and pillowed horizons, and in conjunction with the observed grain size gradation in the massive flows, indicate

a south facing (tops face south) sequence of variable magnetic to non-magnetic volcanic flows. Since these rocks dip steeply to the south it can also be said that they are not overturned. This information can be of incalculable value when trying to determine possible extensions to known auriferous showings, as well as located areas of potential mineral wealth.

Two cross structures have been located via the surface mapping. These structures have a northerly trend and are seen to truncate and cause an offset to the geological continuity. One structure a northeast trending shear zone has been located on L8W at 15+85S. The exact extent of this shear is unclear, but striking at 027° and dipping at 080°E it is believed that it extends northwards to the baseline, as is also shown by the offset in a southwest trending VLF-EM conducting (L12E at 3+00S to L12W at 12+50S). The second mapped structure is found in the vicinity of the principle showing at 0+40W and 1+10S, and has a strike of 156° and a dip of 82° to the southwest, with a relative movement of west block-south and east block-north being noted.

11.0 MINERALIZATION AND MINERALIZED SHOWINGS

All rock types, as mapped during this program display at least minor degrees of metallic mineralization, whether it be primary pyrite or magnetite as in the mafic volcanics, or secondary pyrite as seen in the breccia-alteration zones, with pyrite being the dominant form. Two areas of interest were located, but received only a limited degree of exploration due to the early snowfall. Anomalous assay results were received from grab sampling that was independently conducted at both locations.

11.1 A-Zone

The "A-Zone" was located in the same outcropping as the previously named "Main Showing", but these two targets at

present appear unrelated. A diagram of the A-Zone (Figure 7) showing sample locations and assay results has been included. This showing is located within a dark green, brecciated, carbonatized and magnetic rock that shows silicified and carbonatized fragments with 10-15% fine grained disseminated pyrite. Due to the types and degree of alteration and mineralization, it was believed that these rocks would contain at least anomalous quantities of gold. The assays of up to 0.088 oz Au/ton that were received from grab sampling of this zone show that this was in fact the case (see Appendix I). This showing is coincident with an IP anomaly. (See the geophysics section for a further description)

11.2 B-Zone

The second target or the "B-Zone", located at 6+00W and 7+20S, is the site of previous trenching. As is the case with the A-Zone, the B-Zone has not received a thorough nor complete examination. This showing is found within the intermediate to mafic volcanics, and is distinguished by the apparent silicification, silica filled fractures and 5-7% pyrite mineralization. Grab samples collected from this showing have returned anomalous assays of up 267 ppb Au (0.008 oz Au/ton. This showing is found to be coincident with a southwest trending "mag" depression (L4E-5S to L8W-9S), as well as a similar trending VLF-EM conductor (see Figures 8 and 9).

The IP survey has highlighted an area that shows slightly higher chargeability. This zone is also coincident with the Mag and EM, but the exact form is unknown as the survey boundaries prohibited a full disclosure of this anomalous zone. It is these multiple-overlapping anomalous zones, along with anomalous assay results that place the B-Zone as a very promising exploration target, which will require a thorough field examination next season.

The "Main Showing" as described in a previous report (Conquer, 1986) did not receive any further examinations during this phase of exploration. Although this showing would appear to be of less importance than both the A- and B-Zones, it should still be examined during any further phase of exploration.

The anomalous assay results in conjunction with the coincident geophysical anomalies present both the A- and B-Zones as high priority exploration targets, that should receive a more detailed examination during the next field season.

12.0 GEOPHYSICS (see Figures 8-10 and Maps 6436-86-5-1 to -6)

An orientation Induced Polarization survey was conducted as part of this exploration program. This newly acquired geophysical data was used in conjunction with previously acquired "mag" and VLF-EM data was used to interpret geological and mineralogical trends.

When the A-Zone was found, it was observed that the pyrite content was not high enough to produce a VLF-EM response, but with the observed 2-3% pyrite concentration, would be sufficient to give an IP response. This survey did outline an elliptical zone that extends for approximately 1,000 feet from 3+00W to 7+00W and is about 500 feet wide straddling the baseline. Also from this survey a second weak but distinct chargeable zone was located. As previously mentioned, this zone is coincident with other anomalies that highlight the B-Zone.

The structure which is inferred to be associated with the B-Zone is shown to be at least 5,000 feet long by the VLF-EM and the mag surveys. This does not appear to be one continuous structure, but may be composed of several dependent sections.

Several other parallel to sub-parallel structures can be inferred from the mag data, but apparently lack the similar EM association as is found with the B-Zone. An attempt should be made to further delineate the B-Zone geophysical structure in light of the current evidence.

Analysis of the magnetometer date reaffirms what has been seen from the mapping and that is a series of magnetic to non-magnetic flows. At least within the confines of the Cleyo property, a definite magnetic trend can be seen to exist. This trend shows that the southern portion of the property is dominated by a series of highly magnetic, presumably, "iron-rich" tholeiitic basalts. While other highly mganetic "zones" are defined, they decrease in both length and width becoming only isolated occurrences. As has been shown by the geochemistry, a correlation can be drawn between the high magnetic susceptibility zones and the tholeiitic basalts, as well as the less susceptible or non-magnetic zones and the calc-alkalic rocks.

13.0 CONCLUSIONS

The geological mapping program which was completed over the 27 claim Cleaver Township property of Cleyo Resources, was done so for two reasons. First, to gain a better understanding of the local geology, mineralogy and stratigraphy such that a better insight could be gained into the source of and to extend to the gold bearing zone of the "Main Showing." Second, to locate other areas of possible economic significance. This mapping program was in fact only one part of a previously recommended multiphase exploration program.

It was found that the property was underlain by a series of magnetic to non-magnetic basalts, intermediate to mafic flows and tuffs and localized felsic intrusions. These rocks have a northeast-southwest strike, dip steeply to the south and show a tops up configuration. From geochemical analysis it would appear as if the basalts, both magnetic and non-magnetic varieties are of the iron-rich tholeiitic trend, while the intermediate to mafic flows were magnesium-rich tholeiites.

The amount of structural data acquired through the mapping, precludes any meaningful interpretation beyond the mention that cross-faults or structures are known to exist. Their influence on any auriferous zones is at present unknown, and will only be understood as a result of future exploration.

In light of the completed work, two promising auriferous zones were located. Both the A- and B-Zones were only examined in the most precursory fashion, due to the sudden arrival of winter. These zones have given definitely encouraging results, such that further work is a necessity. Therefore the following recommendations are made.

14.0 RECOMMENDATIONS

With the discovery of two gold bearing zones on the Cleyo Resources property, it is recommended that a two and possibly three phase exploration program be completed, such that these showings can be properly evaluated. The work that has been completed to date was only a small part of a larger scale program, that due to deteriorating weather conditions, could not be completed.

The first phase will consist of linecutting and geochemical sampling. The lines will be cut to facilitate completion of program segments from all phases of work. The sampling and subsequent analysis of the humus and "B"-horizon material across both A- and B-Zones, will serve to generate a "geochemical signature", which it is hoped can be used to show the aerial extent of these auriferous zones, as well as a base against which future geochemistry results can be compared. This work by its very nature must be completed before the stripping is started and the overburden is forever disturbed.

Phase two is designed to actually open up and physically examine both showings plus geochemically investigate other areas on the property. This phase will consist of stripping, trenching, sampling, assaying and geological mapping. Through this work an overall geological picture can be developed, so as to further define the potential economic significance of these showings.

The other areas of interest that are outside the principle showings and that are either geologically or geophysically inferred should be examined. This examination may be best completed via geochemical sampling, especially in areas of poor exposure and shallow overburden (less than 20 feet).

The budget for the geochemical sampling has been calculated for coverage of the entire property. This may in fact not be practical due to overburden thicknesses, but it should be included in the planned program.

Diamond drilling is proposed for the third phase of this program, and will be contingent upon the results of the two previous phases. At the present time a 5,000 foot drill program is envisioned for the two known showings. The planned footage is based upon an equal split of 2,500 feet per showing. Program modifications may be made upon in field results.

The above recommended three phase program is estimated to cost $263,000.00

15.0 COST ESTIMATES

Phase I

Linecutting	
-estimated @ 5 miles for grid extension and detailed lines	
-5 miles @ $325./mile	1,625.00

Mining Recorder
Ministry of Northern Development and Mines
4 Government Road East
Kirkland Lake, Ontario
P2N 1A2

Dear Sir:

RE: Notice of Intent dated February 9, 1987
Geological Survey on Mining Claims
L 724470, et al, in Cleaver Township

The assessment work credits, as listed with the above-mentioned Notice of Intent, have been approved as of the above date.

Please inform the recorded holder of these mining claims and so indicate on your records.

Yours sincerely,

J.C. Smith, A/Manager

Technical Assessment Work Credits

AMENDED

File 2.9683

Date February 9, 1987

Mining Recorder's Report of Work No. 521/86

Recorded Holder: CLEO CLEMENT (IN TRUST)

Township or Area: CLEAVER TOWNSHIP

Type of survey and number of Assessment days credit per claim	Mining Claims Assessed
Geophysical	
Electromagnetic _____ days	
Magnetometer _____ days	
Radiometric _____ days	
Induced polarization _____ days	
Other _____ days	
Section 77 (19) See "Mining Claims Assessed" column	
Geological 40 days	L 724470 724474 725147 to 56 inclusive 725158 725161-62 749741 to 46 inclusive 750507-08 916185-86
Geochemical _____ days	
Man days ☐ Airborne ☐	
Special provision ☒ Ground ☒	
☐ Credits have been reduced because of partial coverage of claims.	
☐ Credits have been reduced because of corrections to work dates and figures of applicant.	

Special credits under section 77 (16) for the following mining claims

20 DAYS GEOLOGICAL

L 916183 - 84

No credits have been allowed for the following mining claims

☐ not sufficiently covered by the survey ☐ insufficient technical data filed

The Mining Recorder may reduce the above credits if necessary in order that the total number of approved assessment days recorded on each claim does not exceed the maximum allowed as follows: Geophysical - 80; Geologocal - 40; Geochemical - 40; Section 77(19) - 60.

The list of past-producers is limited to mines with metal production valued in excess of $25,000.

MINERAL PRODUCTION AND RESOURCES

In 1971, mines located within the Timmins-Kirkland Lake sheet produced gold, silver, cobalt, copper, zinc, lead, nickel, iron, cadmium, sulphur and asbestos. Barite is soon scheduled for production in Yarrow Township. The area also contains deposits of molybdenum, uranium, tungsten, bismuth, palladium, platinum, magnesium, nepheline, marl, sand and gravel. Two kimberlite dikes are known to occur; one in McCool Township, another in Gauthier Township.

Gold is produced at the Porcupine (Timmins), Kirkland Lake-Larder Lake mining camps, and in Hislop Township southeast of Matheson. Former production included the Matachewan and Elk Lake camps.

The largest producer of silver is the Kidd Creek mine north of Timmins. Silver is also recovered at all the producing gold mines, in addition to the operating mines in the Gowganda area. Former production included the Matachewan, Elk Lake and Cobalt (Casey Township) areas.

Zinc, copper, lead, cadmium and sulphur are produced by Ecstall Mining Limited (Kidd Creek mine). Copper and zinc are produced in the Kamiskotia area west of Timmins and at the Potter mine east of Matheson. Copper is also produced at the McIntyre Porcupine mine near Timmins, the Miller Lake-O'Brien mine near Gowganda and the Upper Beaver mine near Larder Lake. Minor copper has also been produced in the Elk Lake, Matachewan and Gowganda areas. Minor lead-zinc was formerly produced in the Matachewan area.

Nickel production commenced in 1971 at the Texmont mine located south of Timmins. Noranda Mines Limited will shortly be producing nickel from Langmuir Township, southeast of Timmins. Nickel was formerly produced at the Alexo mine, located northeast of Timmins.

Iron ore is produced at the Adams mine of Dominion Foundries and Steel Limited, located in Boston Township, south of Kirkland Lake.

Nearly all the asbestos production has come from the area east of Matheson, and most of this has been from the Munro mine, a past producer of Canadian Johns-Manville Company Limited. Hedman Mines Limited is producing asbestos in Warden Township, and Canadian Johns-Manville is currently preparing a property for production in Garrison Township; both localities are east of Matheson.

Cobalt is produced in the Gowganda area, and was formerly mined in the Elk Lake and Cobalt (Casey Township) areas.

Total value of mineral production from the map area to the end of 1969 was approximately $3,551,000,000. Quantity of minerals produced is as follows:

Gold	85,508,683 oz.	Copper	532,850,393 lbs.
Silver	130,249,224 oz.	Zinc	1,500,900,863 lbs.
Cobalt	1,726,139 lbs.	Lead	53,223,216 lbs.
Cadmium	6,808,922 lbs.	Nickel	174,287 lbs.
Tungsten	454,866 lbs.	Asbestos	370,209 tons
Molybdenum	11,393 lbs.	Iron	5,609,583 tons
		Sulphur	26,788 tons

HOW TO OBTAIN ADDITIONAL INFORMATION

Published geological maps covering this sheet are indicated on Index Maps 2079, 2080 and 2081 of the Ontario Division of Mines, Ministry of Natural Resources, Toronto, and on Index sheets 31, 32, 41, and 42 of the Geological Survey of Canada, Department of Energy, Mines and Resources, Ottawa.

Published geological reports covering this sheet are listed in Bulletin No. 25 of the Ontario Division of Mines, Ministry of Natural Resources and in the Index of Publications, Geological Survey of Canada, 1961, 1970.

Topographic maps of the area can be obtained from the Division of Lands, Ministry of Natural Resources, Toronto, or the Topographic Survey, Department of Energy, Mines and Resources, Ottawa.

Air photographs may be obtained from the Silviculture Section, Division of Lands, Ministry of Natural Resources, Toronto, Ontario, or from the National Air Photographic Library, Department of Energy, Mines and Resources, Ottawa.

Aeromagnetic maps covering this sheet can be obtained from the Geological Survey of Canada. Partial coverage may be obtained from the Ontario Division of Mines.

The name and ownership of many mineral occurrences shown on this sheet are given on Map 2148, Ontario Mineral Map, 1968.

Information on geology, mines and mineral occurrences may be obtained at the office of the local Resident Geologist (Timmins, Kirkland Lake or Sudbury).

Mining claim maps and general information can be obtained at the office of the Mining Recorder at Timmins, Kirkland Lake, or Sudbury, or at the Division of Lands, Toronto.

F - balsam fir
A - alder
C - cedar
Pop - poplar

GEOCHEMICAL ROCK NAMES

Tholeiitic Suite
FT - iron-rich tholeiitic basalt
BT - tholeiitic basalt
AT - tholeiitic andesite
RT - tholeiitic rhyolite

Calc-Alkalic Suite
BC - calc-alkalic basalt
AC - calc-alkalic andesite
RC - calc-alkalic rhyolite
DC - calc-alkalic dacite

A-ZONE assay results

-0014 10 ppb
-0015 7 ppb
-0016 14 ppb
-0017 19 ppb
-0018 77 ppb
-0019 0.088 oz Au/ton
-0020 34 ppb
-0021 549 ppb
-0022 343 ppb
-0023 349 ppb
-0024 490 ppb

B-ZONE assay results

Trench 1
-0038 221 ppb
-0039 12 ppb
-0040 267 ppb
Trench 2
-0041 27 ppb

Scale 200' 400' 800'

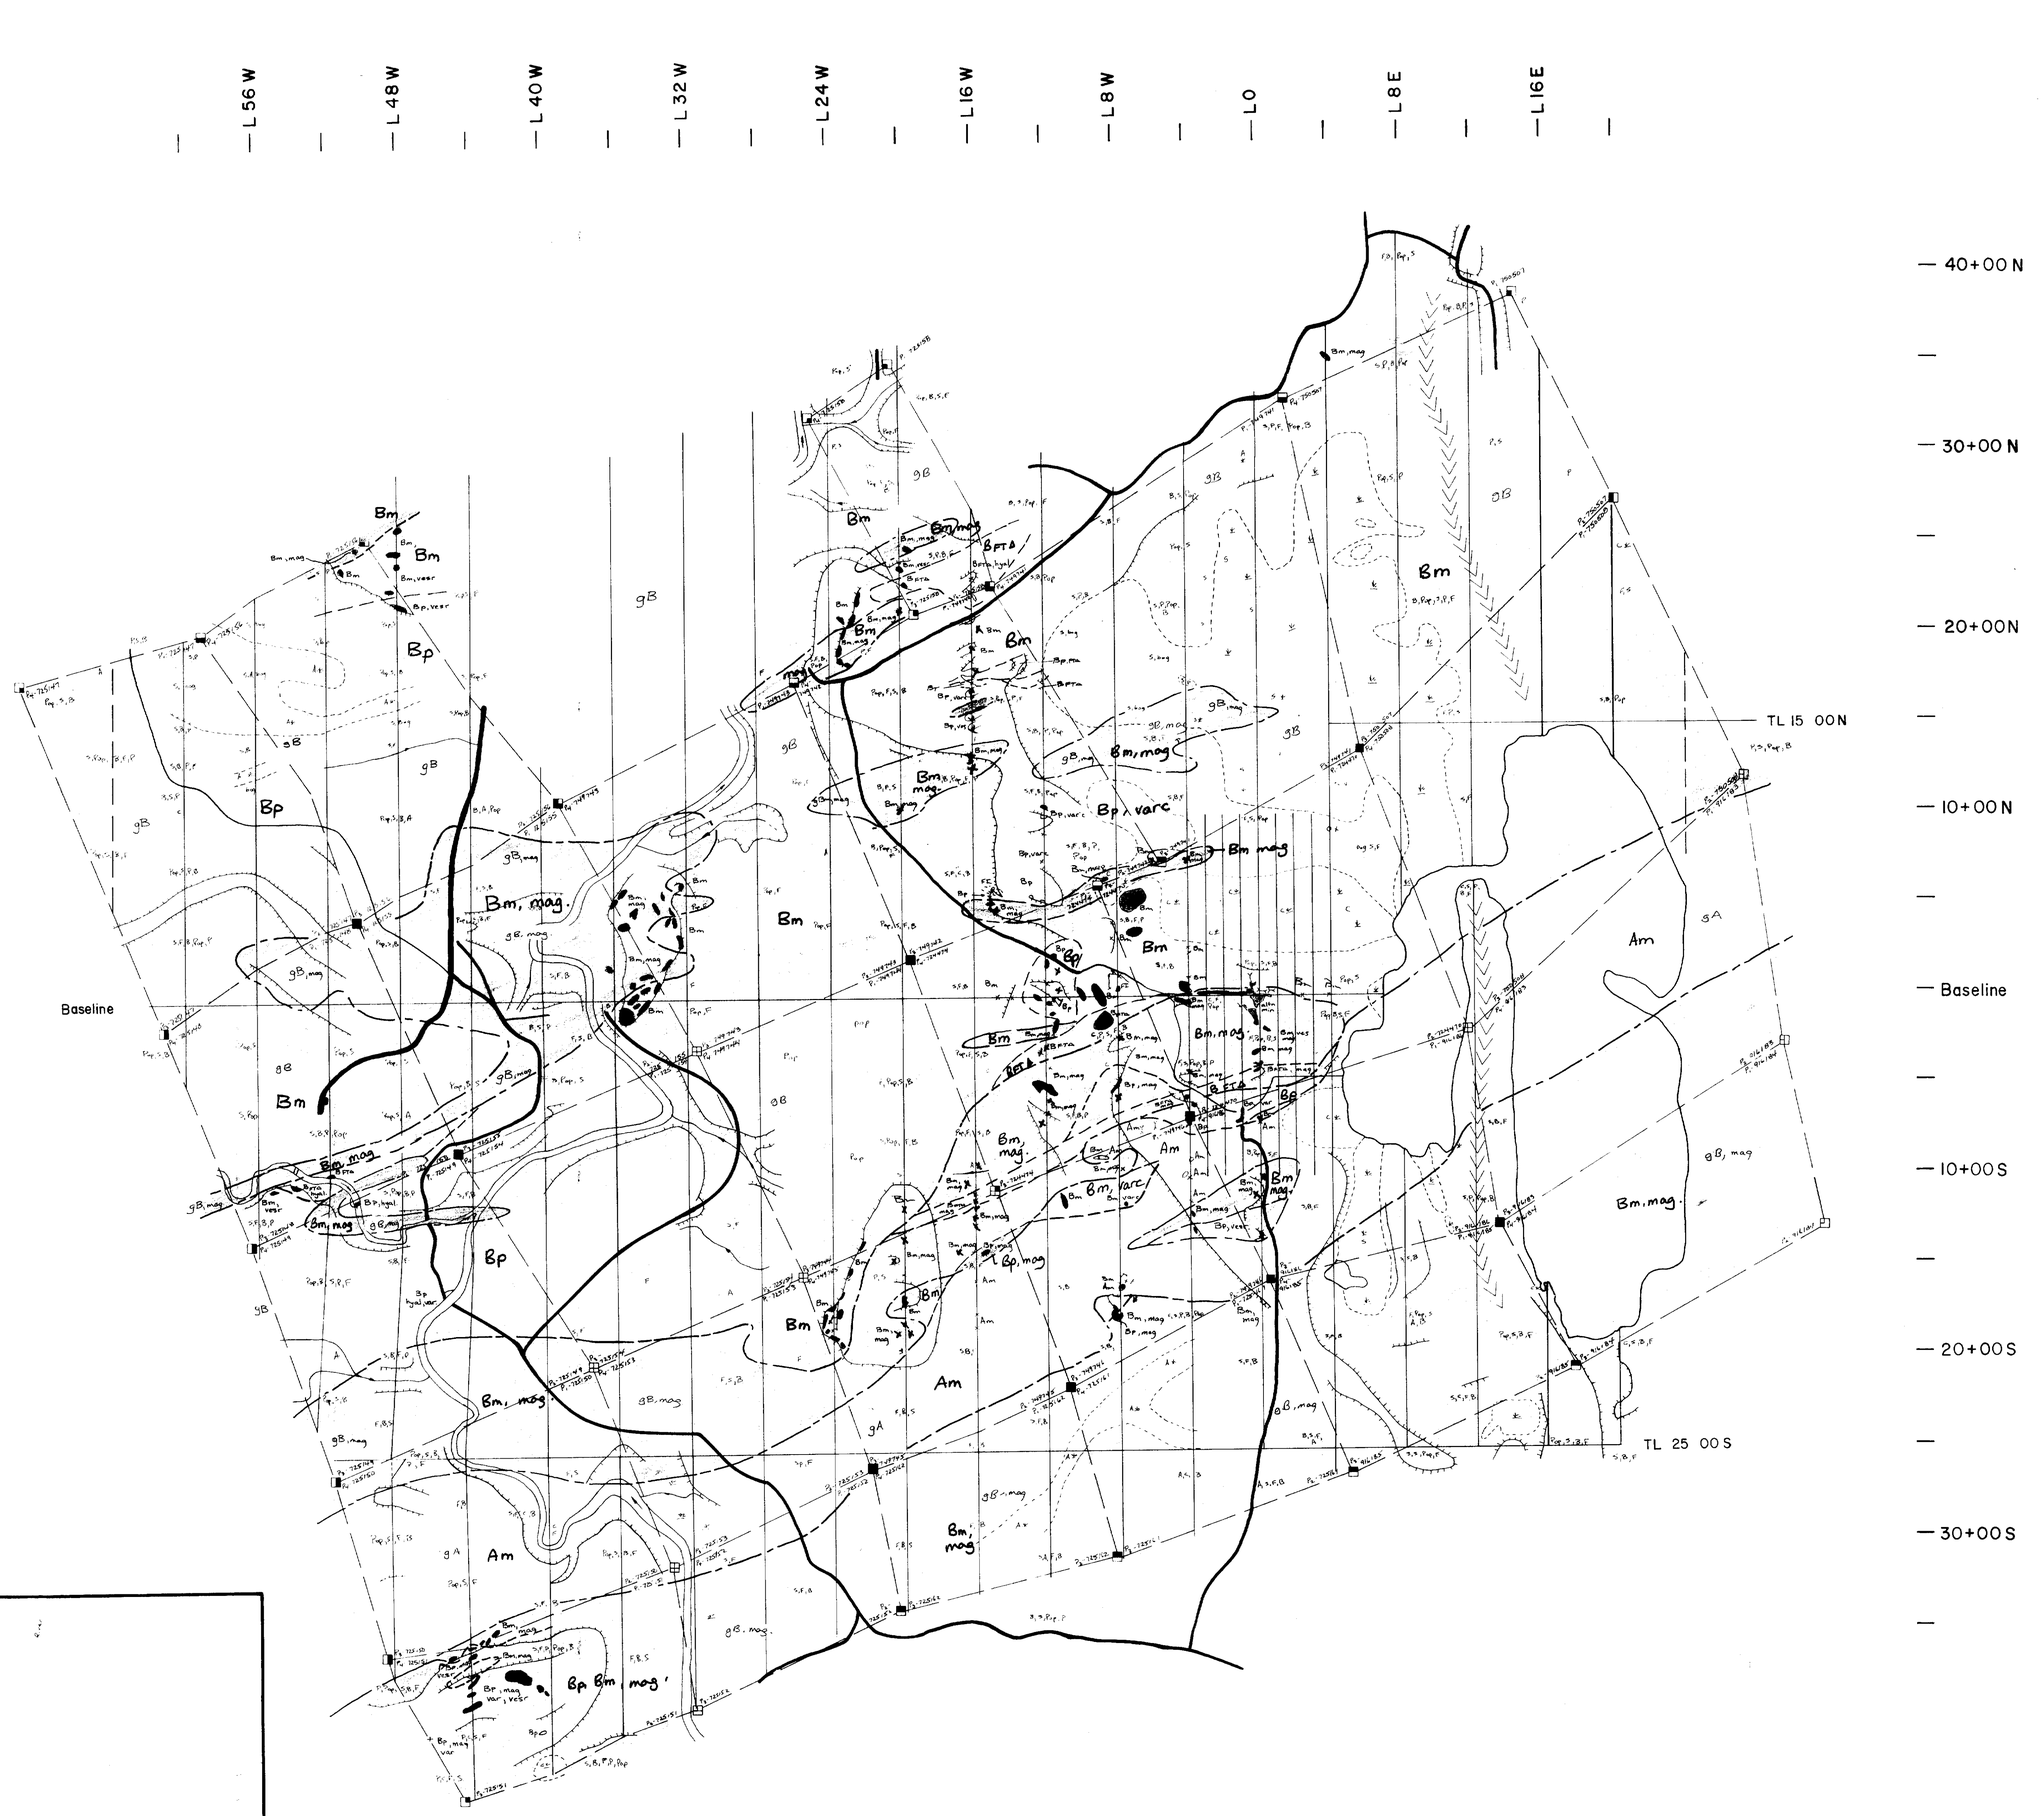
Sample Location 29683 and Assay Plan

Twp/Area : Cleaver Twp.	Prov : Ontario
Mining Division : Larder Lake	Project No : 6436
References :	NTS No : 42 A/2 .D
Drawn : S.L.C. Drafted : S.L.C.	Checked : S.L.C.
Scale : 1" = 400' Date : Dec. 1986	Sheet No : 84 of 93



LEGEND

MAFIC ROCKS
- ☐ Non-magnetic
  - B -basalts undifferentiated
  - Bm -massive flows
  - Bp -pillowed flows
  - B_{PT} -flow top breccia
  - Bt -tuffaceous
- [] Magnetic
  - B basalts undifferentiated
  - Bm massive flows
  - Bp pillowed flows
  - B_{PT} flow top breccia
  - Bt tuffaceous

INTERMEDIATE - FELSIC ROCKS
- ☐ Non-magnetic
  - A -andesite undifferentiated
  - Am -massive flows

FELSIC INTRUSIVES
- ☐ FI -unsubdivided

SYMBOLS
- Geological Contact
- based on magnetic data and geology
- based on geology and geochemistry
- claim post location and number found , assumed
- elevation contours hash marks show down slope
- esker
- road
- swampy ground

Tree Types
- S - spruce
- P - pine
- B - birch
- F - balsam fir
- A - alder
- C - cedar
- Pop - poplar

- vesr - vesicular
- hyal - hyaloclastite
- var - variolitic
- mag - magnetic
- g - geophysically inferred
- sh z - shear zone
