ANALYSIS OF DRILL CORE FROM CARSCALLEN TWP.

BIGMASH LAKE PROPERTY

CARSCALLEN TWP. (G3040)

NTS: 42A/5

MAY 1996

ANDREA WALDIE
(FOR LIONEL BONHOMME)

REPORT

In July of 1996 a total of 86 rock drill core samples were collected from core stored at the Timmins Core Library. Sample intervals averaged 1-2 feet in width. The interval was split with half of the sample being sent to TSL for whole rock analysis along with selected samples being submitted to Swastika Labs for gold and base metal geochemical analysis. The report of analysis is included within.

Samples 16839 - 16850 and 59601 - 59669 were obtained from holes BM-1, 3, 4, 7, 8, 9, 10 drilled by Cleyo Resources in 1983 in the SE corner of claim 1189844 in Carscallen Twp. Samples 59670 - 59677 were obtained from hole 93BM-01 drilled by BHP Minerals Canada Ltd. In 1993 in the NE corner of claim 1189844. Refer to the accompanying Drill Hole Sample Analysis Information list for a complete breakdown of sample information. The Drilling Compilation Map shows the location of the drill holes.

In addition to the laboratory analysis, 13 samples were submitted for petrographic work. This report is included which contains descriptions for each sample and general observations. Information as to sample location is provided on the Drill Hole Sample Analysis Information list and on the accompanying map. Note, samples 26744, 26746, 26749 and 26750 are located outside claim 1189844 and have not been included in the assessment cost breakdown.

Petrographic Report for Lionel Bonhomme
Timmins Samples
by Wallace H. MacLean
October 7, 1995

This group of 13 samples was received in September. Their Numbers are:

16833*	26733	59601	* = polished-thin section.
16837	26744	59625	
16838	26746	59641*	
16840*	26749	59672	
		26750	

General Observations.

All of the samples are very rich in carbonates, ranging up to ~60 %. Carbonate is a matrix of all the rocks, and is also common as cross-cutting veins, amygdale fillings and as irregular masses. It is almost always coarse-grained, more so than the silicate components. This very intense carbonitization has often obliterated primary textures, so that the original identities of many samples are not well known.

Rock Types. The majority of the samples appear to be sedimentary rocks or reworked tuffs - mainly felsic. There are at least a couple of mafic lavas in the group, whose identity relies largely on the presence of substantial (1 to 3 %) leucoxene (TiO_2), lack of quartz phenocrysts and matrix, and presence of "ghost" plagioclase phenocrysts in one sample. In addition to carbonate, the felsic samples have a matrix of fine grained quartz and abundant sericite. Other minerals are abundant in a few samples: Berlin Blue chlorite is widespread in a few samples, and minor epidote is present in a few.

Shearing. Most, if not all, samples are sheared, some very strongly. Sericite is prominent along all shears, and these cut all carbonate textures except some large carbonate veins. The carbonitization was active early and continued to some extent after the shearing event.

Amygdales. The amygdales are round to oval shaped grains of polygranular quartz+carbonate in all samples but one which is filled with a Berlin Blue chlorite. In many samples, they are definitely amygdales in volcanic rocks or rock fragments, but in a few others they appear to be detrital grains in sand- and siltstones. That is, they may have weathered out of the rocks without losing shape. Some amygdales are in definite basaltic rocks, and others in felsic ones. I recognized a quartz phenocrysts in only one sample, and that one is a sandstone or reworked felsic crystal tuff.

Mineralization and Alteration. Three polished thin-sections were cut to look at ore minerals. In #16840 there is about 25% sphalerite, 10% pyrite, and traces of chalcopyrite and pyrrhotite. Sphalerite was also identified in #16833, and small grains of chalcopyrite in pyrite in #59672. In a couple of samples, Berlin Blue chlorite is abundant, and this type of chlorite is very commonly associated with massive sulphide mineralization. Sericite and carbonate are too widespread to associate directly to mineralization, but a lot of the sericite was formed prior to the shearing.

Conclusions. A few of the samples are basalts, and the rest are felsic volcanic-derived sediments. All of them have been heavily carbonatized. They are moderately to strongly sheared and are heavily sericitized. A few samples are chloritized and mineralized, and

this is good evidence that a metal-generating hydrothermal system was active in the vicinity of these rocks.

Description of Samples.

Magnifications are for the photographic print.

#16833 Very Carbonitized Rock with Sphalerite and Pyrite

- 50% carbonate, and zones very rich in sericite and containing some chlorite and ~5% fine grained quartz. There is no evidence of phenocrysts, and no feldspar, but there are numerous round amygdules of Berlin Blue chlorite, and this chlorite is in the matrix as well.
- the carbonate matrix and the chlorite amygdules are cut by many shears lined with sericite.
- ~3% fine grained sphalerite and 5% pyrite grains in the matrix.
- The lack of leucoxene (TiO_2) indicates a felsic volcanic source.
- *Photo #1.* Amygdules of Berlin Blue chlorite in a matrix of carbonate and some sericite; late shearing, with concentration of sericitic along shear planes. X40.

#18637 Very Carbonitized Probable Basic Rock

- 70% carbonate as matrix and prominent veins.
- The 30% silicate portion is composed of fine grained quartz and albite, and 3-4% leucoxene, the latter suggesting it was a basaltic rock.
- An early set of quartz-rich veins contain abundant albite.
- Sericite is abundant along the many shears.
- *Photo #2* Vein of Carb with intricately twinned carbonate grains. 40X.
- *Photo #3 & #4.* Chlorite and carbonate cut by sericitic shears. 40X.

#16838 Very Altered Silicic Rock

- A very fine grained quartz-rich rock, with many patches of Berlin Blue chlorite, sericite and carbonate. It is much less carbonated than the previous samples. Also, there is no evidence of shearing here.
- Qz = 65%, carbonate = 15%, sericite and chlorite ~10% each.
- A quartzose sediment or reworked felsic tuff.
- *Photo #5.* Large sericite grain in quartzose matrix. 175X.
- *Photo #6.* Berlin Blue chlorite and carbonate in quartzose matrix. 40X.

#16840 Mineralized Silicic Sediment or Reworked Tuff

- The matrix is fine-grained quartz and other minerals: - minor sericite, chlorite, epidote, carbonate.
- 25% sphalerite, 10% pyrite, 65% siliceous matrix. Traces of chalcopyrite and pyrrhotite.
- *Photo #7.* Sphalerite + Pyrite + Silicates. Reflected light. 275X.
- *Photo #8.* Sphalerite + Silicates - the yellow-orange translucent mineral is sphalerite. transmitted light. 274X.

#26733 Carbonated Quartz-Sericite Rock

- Carbonate = 35%, quartz = 30%, sericite = 30%, other = 5%. Minor pyrite and leucoxene.
- *Photo #9.* General view of wide sericitic-quartz zones, cut by narrow irregular veins of brown carbonate. 40X.
- *Photo #10.* Details of coarse carbonate and fine grained sericite-quartz zones in above photo. 175X.

#26744 Very Carbonated Rock (Volcanic ?) with Quartz Amygdules

- 40% carbonate, 30% sericite, 25% quartz, 5% Berlin Blue chlorite.
- Numerous quartz amygdules, indicating a volcanic rock precursor.
- The sericitization appears to be late and associated with the shearing.
- *Photo #11.* Sericitic shears cutting coarse brown carbonate and quartz matrix. 40X.
- *Photo #12.* Quartz amygdale in Carb-Qz-Ser matrix. 40X.

#26746 Altered Basic to Intermediate Rock

- Fine grained matrix enclosing "ghost" plagioclase phenocrysts.
- Matrix is 60% quartz, 20% carbonate, 10% sericite, 5% Berlin Blue chlorite, 3% leucoxene.
- The plagioclase phenocrysts and relatively abundant leucoxene indicate at least an intermediate rock.
- *Photo #13.* Ghost plagioclase phenocrysts in fine grained matrix. 40X.

#26749 Reworked Felsic Volcanic - Sedimentary Rock

- There are grains of single-crystal quartz that are probably phenocryst fragments, ~ 5-8%.
- The matrix is medium grained and consists of 40% quartz, 35% carbonate, 20% sericite, 5% other.
- It looks like a reworked rhyolite tuff.
- *Photo #14a.* Single-crystal quartz grains that appear to be fragments of quartz phenocrysts, in a Qz-Carb-Ser matrix. 40X.

#26750 Reworked Felsic Volcanic - Sedimentary Rock - Carbonated

- The silicate portion of this rock is massive with a fine grained equigranular texture of quartz, sericite and carbonate. It also contains well formed quartz amygdules, and because of these, it appears to be a rhyolite.
- There are no phenocrysts, and no feldspar was seen.
- 50% carbonate as veins and matrix.
- *Photo #15a.* Small quartz amygdules in fine grained quartz-rich groundmass containing sericite and carbonate. 40X.
- *Photo #16a.* Enlargement of groundmass of #15a: Qz+Carb+Ser. 175X.

#59601 Reworked Felsic Volcanic - Sedimentary Rock - Carbonated

- Quartz-sericite matrix, much carbonate,

- Round and oval shaped quartz amygdale grains that appear unrelated to the matrix; the rock has a detrital texture. The amygdales may have remained intact as a postulated rhyolite disintegrated.
- *Photo #17a (also #18 on negative).* Rock of fine grained sericite + quartz + carbonate with oval shaped grain of what appear to be a quartz amygdale. Probably a sediment derived from an amygdular rhyolite. 40X.

#59625 Carbonate-Rich Sedimentary Rock

- 60% carbonate as coarse grains in matrix and as cross-cutting veins.
- The remainder is 25% sericite and 15% quartz.
- The rock is sheared, with sericite concentrated close to the shear planes.
- The sample contains a layer or large 'pebble' of fine grained quartzite.
- *Photo #19.* Carbonate matrix of rock cut by shears along which sericite and quartz are concentrated. 40X.

#59641 Drill Core of Carbonate-Rich Rock -with Sharp Colour Change

- Polished thin-section.
- The core is divided sharply into a dark and a light zone.
- The light zone is a heavily carbonated rock cut by shears and zones of quartz-sericite. This part of the sample also contains pyrite grains with small inclusions of chalcopyrite. The carbonate is much coarser grained than the silicate part of the rock.
- *Photo #20.* The light zone shears with sericite and quartz cutting through coarse carbonate. 40X.
- The dark zone is characterized by altered carbonate grains containing a lot of fine grained opaque mineral, which in reflected light is identified as iron oxide, - hematite or goethite. This was an oxidation process which apparently altered and degraded an Fe-bearing carbonate and pyrite of the light zone rock to this dark and porous material. The alteration boundary is very sharp. It is caused by oxidation, and could be due to weathering or circulation of other oxygenated water. It is not likely to have any relation to the mineralization.
- *Photo #21.* Boundary between the carbonated light zone and the oxidized hematite bearing dark zone. Note that the sericite in the shears becomes rust stained in the dark zone. 40X.
- *Photo #24.* Polished thin-section: reflected light. Light zone: pyrite grains containing inclusions of chalcopyrite. 63X.

#59672 Amygdaloidal Basalt

- Fine grained basaltic rock containing numerous carbonate-quartz amygdale in a matrix that is carbonated and sericitic.
- There is ~2% leucoxene (TiO_2).
- Shears are accentuated with sericite, - 10% of rock.
- About 25% carbonate in rock.
- *Photo #22.* Broken carbonate-quartz amygdale in carbonated and sericitized rock groundmass of basaltic rock. 40X.
- *Photo #23.* Detail, illustrating shears and intensity of sericitization in the basalt. 175X.

Dear Sir or Madam:

Submission Number: 2.16712

Subject: Transaction Number(s): W9660.00404

After reviewing the Work Report(s) we have prepared this letter and the attached summary, which lists the results of our review. Requirements of the Assessment Work Regulation may not have been fully met. Please examine the summary to determine the next course of action concerning the identified Work Report(s).

NOTE: The 90 day deemed approval provision, subsection 6(7) of the Assessment Work Regulation, is no longer in effect for this submission.

PLEASE NOTE ANY REQUESTED REVISIONS MUST BE SUBMITTED IN DUPLICATE.

If the anniversary dates for the mining claims affected by this correspondence have not passed, a number of options are available. Please contact the Mining Recorder to discuss these options.

If you have any questions regarding this correspondence, please contact Steve Beneteau at (705) 670-5855.

Yours sincerely,

A handwritten signature in black ink, appearing to read "Ron C. Gashinski".
