Lithology Identification

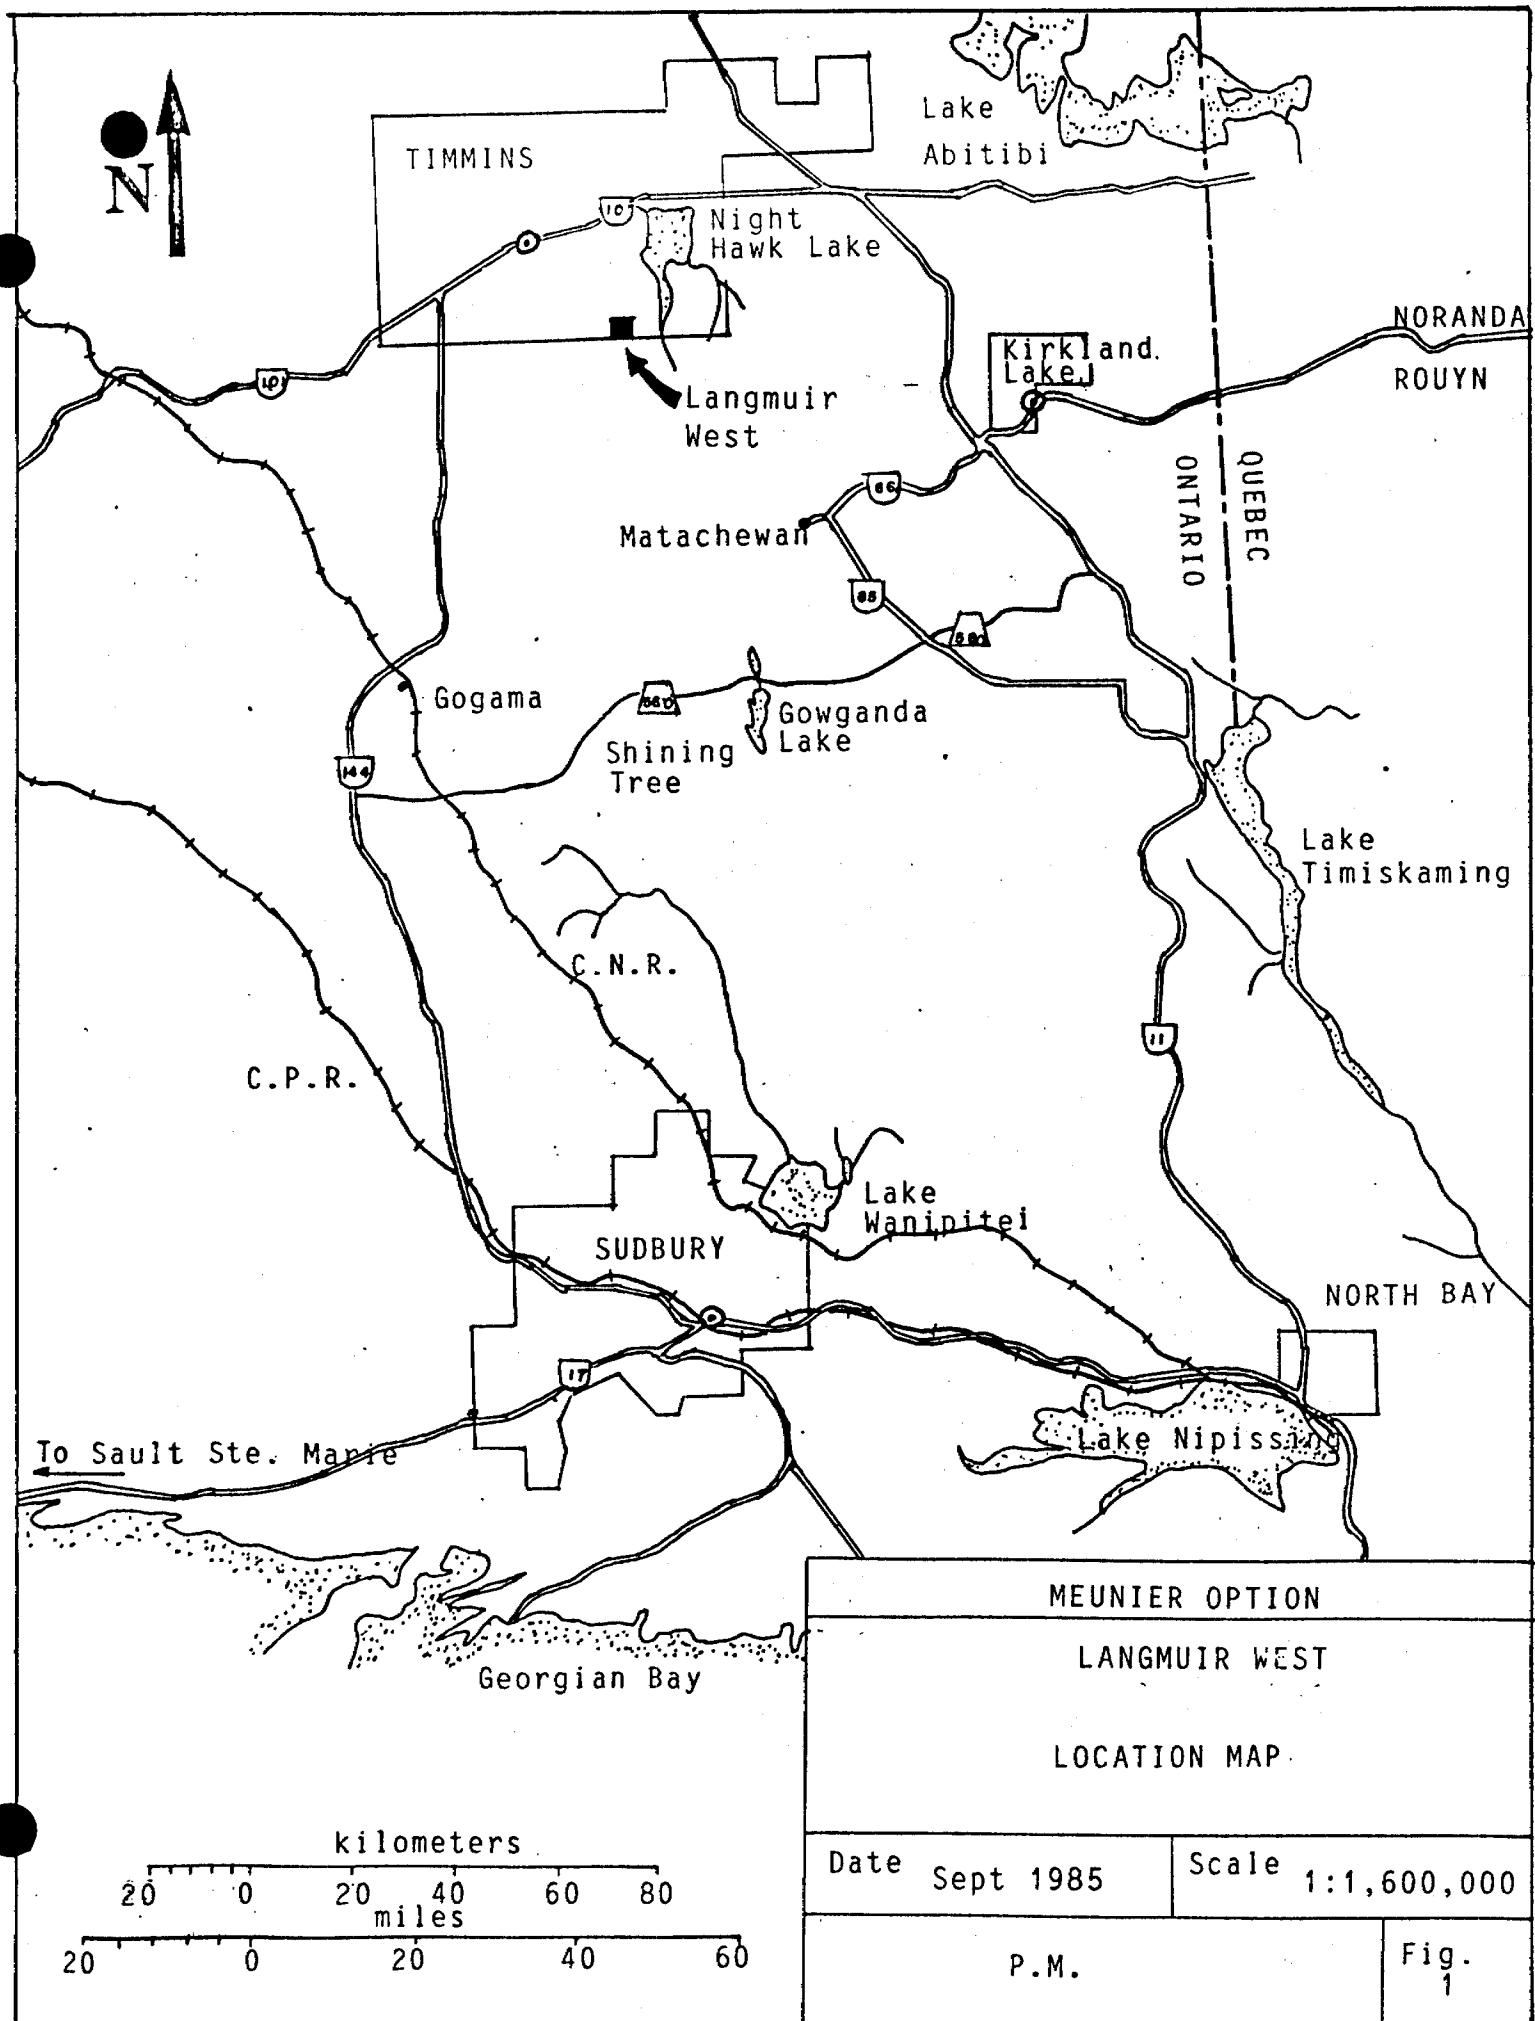

Introduction and Summary of Results

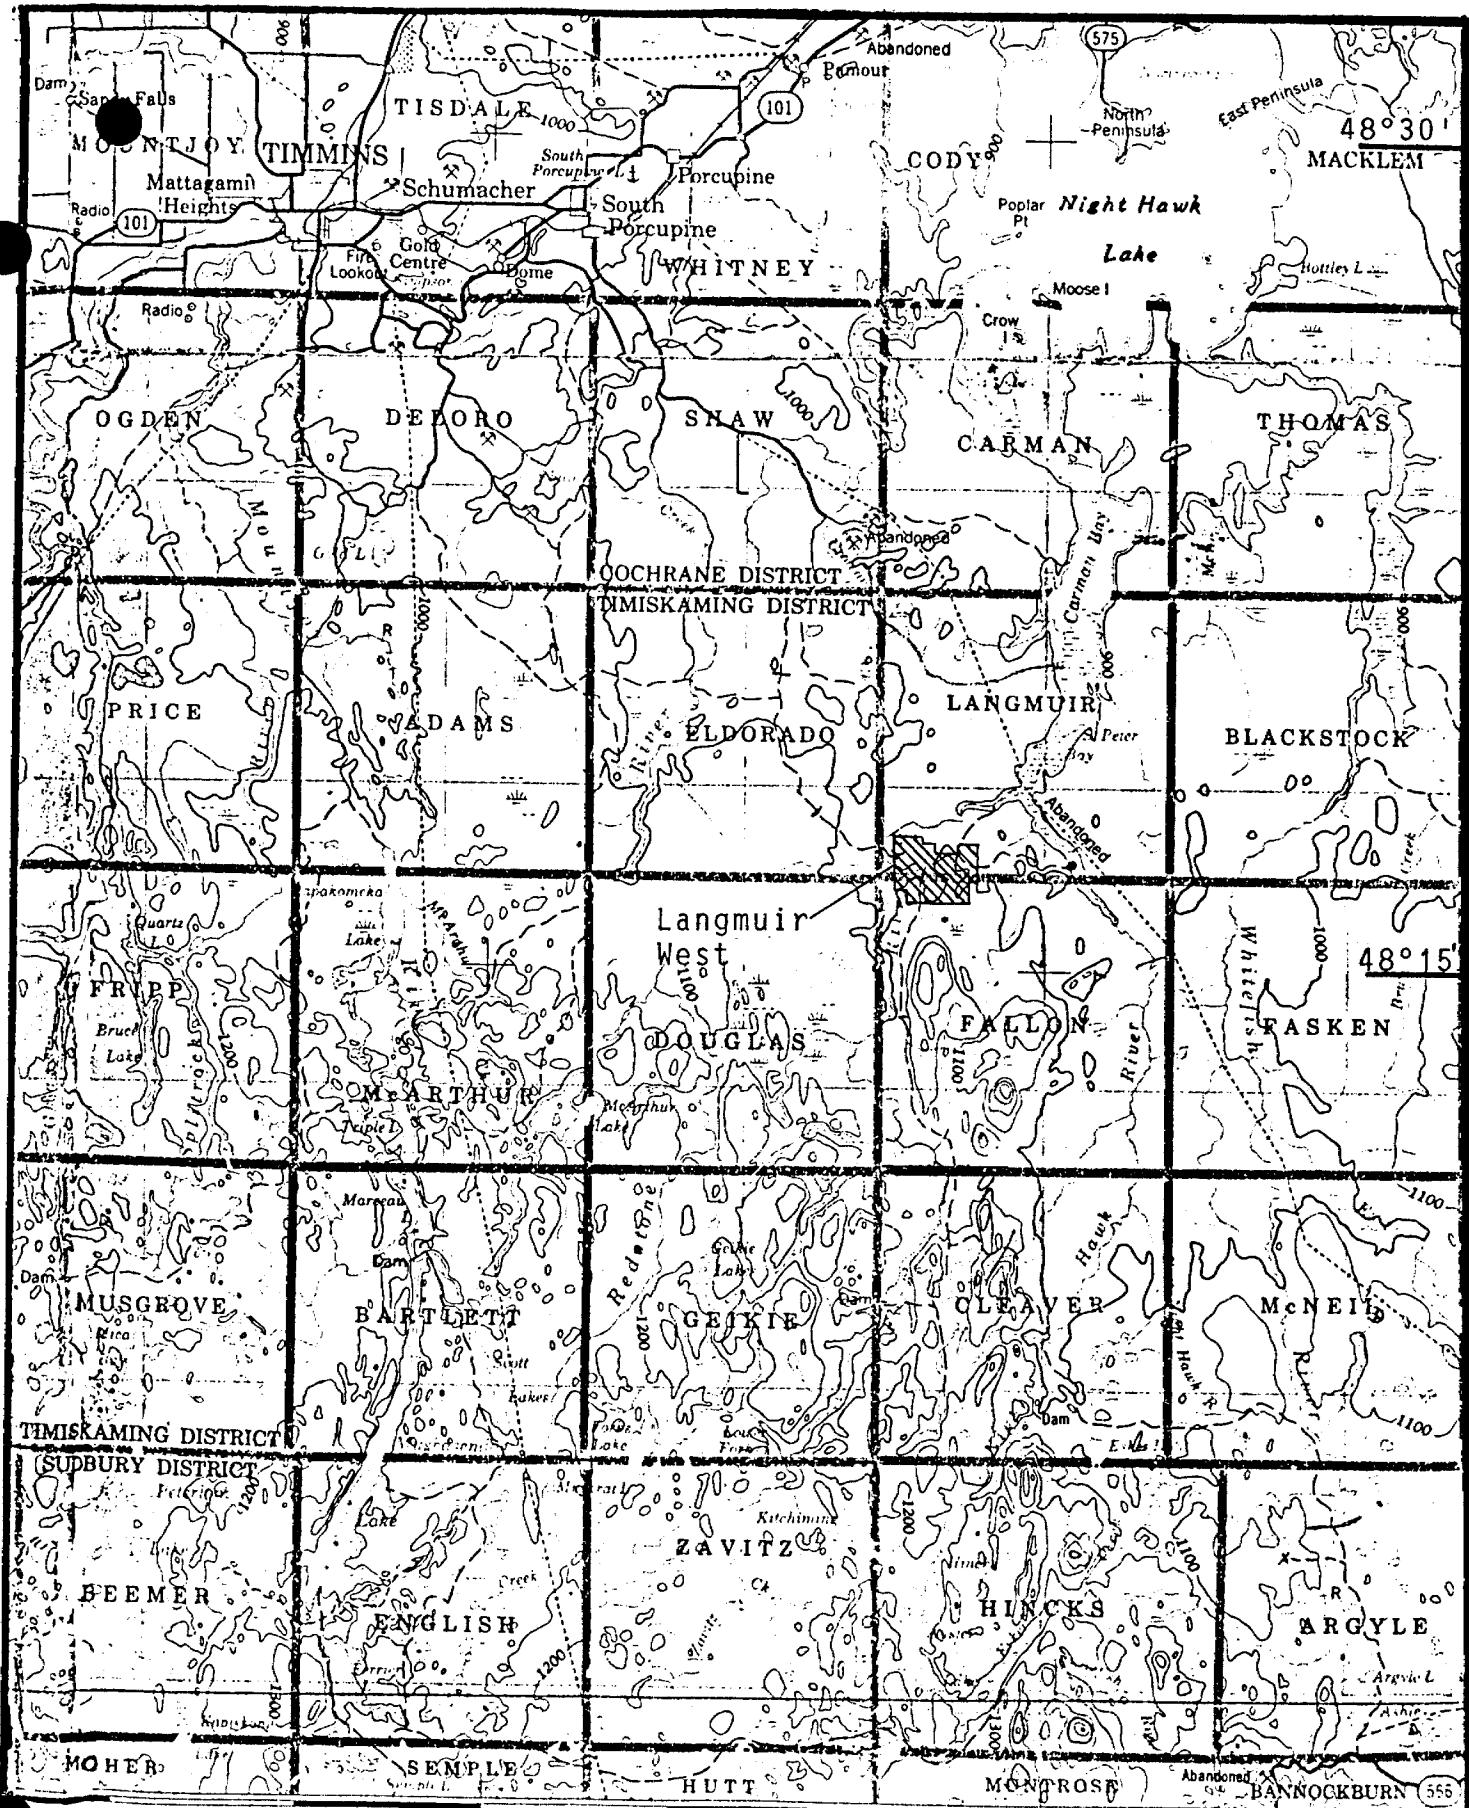

This report describes the results of a basal till sampling program designed to determine the causative sources of VLF electromagnetic anomalies, previously outlined in a geophysical survey performed in 1984. Valuable information was gained about the bedrock geology and the type of overburden in the vicinity of the conductors. The Langmuir West property is situated in Langmuir and Fallon townships 30 kilometers southeast of the city of Timmins. Mr. David J. Meunier of South Porcupine, Ontario is the owner of the surveyed claims.

R. Cormier and Associates Ltd. were contracted to carry out the basal till sampling program between May 29 to June 9, 1985 utilizing a pionjar drill. Five lines of holes were drilled over four separate conductors. Holes were drilled at 25 and 12.5 meter intervals along grid lines trending at 000°. In total 45 holes with an aggregate length of 294.1 meters were drilled. Microscopic, mineralogical and lithological identifications were respectively performed on the heavy mineral separates of the -5 to +250 mesh and the entire +5 mesh size fractions of the overburden samples. The -5 to +250 mesh identifications were done by C.F. Gleeson and Associates Ltd. and the +5 mesh identifications were done by the author of this report. All of the size fraction, heavy mineral and magnetic mineral separations were completed by R. Cormier and Associates Ltd.

Basal till was identified as being sampled at 65% of the sample locations. The average weight of sample recovered was 230.7 grams, from an average depth of 6.53 meters. The basal till generally had a thickness of less than 0.5 meters. Overburden logs, prepared by the drill contractor, failed to identify the basal till, which is present in many of the holes. Most of the logs indicated an organic layer overlying either clay and silt ± sand or gravel and silt ± sand horizons.

The mineralogical and lithological identifications failed to identify the causes of any of the conductors. Lithological, +5 mesh, clast identification indicates that mafic and intermediate volcanics, monzonite and Huronian sediments underlie, or are immediately up ice from the holes drilled near the baseline on lines 6W and 7W. Ultramafic volcanic flows, Huronian sediments and diabases were the major lithologies identified in holes drilled between 0+75S and 4+00N on lines 6E and 8E. One to three percent pyrite was observed in four holes, between 1+00N to 1+50N on line 7W, in the heavy mineral separates. Siliceous intermediate tuff clasts, some of which host 2-3% pyrite, are associated with the pyrite anomalous heavy mineral samples.

LOCATION MAP
LANGMUIR WEST PROPERTY
scale 1:250,000

Fig. 2

Location and Access

The property is centered 30 kilometers southeast of Timmins, Ontario at latitude $48^{\circ} 16.5'$ north and longitude $81^{\circ} 03'$ west, NTS 42A/6. Figures 1 and 2 illustrate the property's location at 1:1,600,000 and 1:250,000 scales respectively. Gravel road access is available into the centre of the property commencing at Connaught Hill, south of South Porcupine. From Connaught Hill, the Langmuir Mine Road is followed in a south-westerly direction for 15.2 kilometers until it's junction with Night Hawk Timber Co. Ltd's. private access road is met. The access road is then followed for 15.0 kilometers, in a southerly direction, until the grid is reached. A walking trail accesses the northeast portion of the grid.

Physiography and Vegetation

The grid area is low lying with variances in elevation being less than 20 meters. Steep-sided erosional remnants of Cobalt Group sediments form the region's prominent topographical features.

Spruce, balsam and minor poplar forest covers most of the grid's northern portion with the exception of a 200 meter wide, north-south trending area, coincident with the north ends of lines 2W and 3W. This region is covered by muskeg - alder swamp surrounding a beaver pond and it's northerly draining

creek. The southwest sector of the grid is logged with much of it having been replanted in the spring of 1985. Most of the southeast of the property is covered by spruce-balsam-alder-muskeg swamp. Drainages flow north and include the Forks River which abutts the western boundary of the property. A small creek runs in a northerly direction through the southeast of the grid.

Property Description

The Langmuir West property is centered around the one mile post on Langmuir and Fallon Townships' common boundary, Porcupine Mining Division, District of Timiskaming, Ontario. Pionjar drill holes were completed on unpatented claims P-758882, P-758883, P-758886, P-758887 and P-825716. Claims on which assessment work is being applied for are listed below:

<u>Claim Number</u>	<u>Number of Claims</u>
P-758882	1
P-779600	1
P-825716	1
P-826278	1
P-826279	1
P-826282	1

Total	8

Survey Procedure

Basal till sampling was conducted between May 29 - June 9, 1985, by a two man crew utilizing a pionjar drill. The pionjar drill is a portable precussion drill that obtains a single overburden sample from each hole, over a 20 centimeter long interval, immediately above the bedrock-overburden interface. Between 8 and 10 holes were drilled at 12.5 and 25.0 meter intervals, along 000° trending metric grid lines, across the conductors. Five lines of holes were drilled across four separate conductors. In total 45 holes having an aggregate length of 294.1 meters were completed. Weights of recovered samples ranged from 103.6 to 384.5 grams, having an average of 230.7 grams. Drill logs, summarizing the types of overburden encountered, were completed simultaneously with the drilling, by the drill crew personnel.

Sample preparation was done by R. Cormier and Associates Ltd. Initially the samples were screened into +5, -5 to +250 and -250 mesh size fractions. The -5 to +250 mesh fraction was then subjected to heavy liquid separations using tetrabrom-aform (2.96 gm/cm^3) and methylene iodide (3.2 gm/cm^3). Grains having specific gravities of between 2.96 to 3.2 gm/cm^3 and greater than 3.2 gm/cm^3 were then subjected to magnetic separations. Microscopic examination of the magnetic and non magnetic portions of the -5 to +250 mesh size fraction, with a specific gravity of greater than 3.2 gm/cm^3 , was completed by C.F. Gleeson and

Associates Limited. The +5 mesh size fraction underwent binocular microscopic examination by the author of this report.

Property Geology

The description of the property's geology, is taken from the result of a geological mapping survey which was performed during the summer of 1985, for Mr. David J. Meunier. This mapping was, in part, completed by the author of this report.

Lithology

Approximately 5% outcrop is exposed on the property, being mainly confined to the area between lines 3E to 10E, north of 1+00N. With the exception of the Proterozoic Cobalt Group sediments, all lithological units are Archean in age.

Komatiite ultramafic flows comprise the majority of outcrop over the north central grid area. A 15 to 20 meter thick pillowed basaltic komatiite occurs as a flow unit within the komatiite flow sequence. Several thin east-west trending quartz-feldspar and feldspar porphyry dikes and a thick north-south trending diabase dike have sequentially intruded the ultramafic flows. Exposed, south of the baseline on line 12E, mafic to intermediate volcanic flows with a thin intercalated tuff horizon stratigraphically overlie the komatiite flows.

An east-west trending gabbro sill and a north-south trending diabase dike intrude the volcanics.

Ultramafic komatiite flows are fine grained, magnetic, brown weathering, variably altered units with individual flows, have thickness' ranging from less than one meter up to several tens of meters. Fresh, they are black to green-grey in colour displaying spinifex, polygonal jointing and less commonly, knobby peridotite and flow top breccia textures. On the north end of lines 3E to 6E the ultramafic flows have undergone varying degrees of carbonate, serpentine, talc and pyrite alteration, adjacent to the porphyry dikes. Elsewhere, the flows are weakly to moderately serpentinized. The basaltic komatiite pillow flow weathers green, is light grey-green in colour when fresh, and has pillows varying from 30 to 70 centimeters in diameter.

Mafic to intermediate flows occur as massive to pillowed, light green to green-grey weathering fine-grained units. Fresh, they are green to dark green-grey in colour. Commonly, they are chloritically altered and occasionally they contain minor quartz-carbonate veinlets and trace to one percent pyrite. A thin 10 meter thick banded tuff unit is exposed on line 12E at 4+50S. The gabbro intrusive is medium to coarse-grained, weathers brown, has a knobby texture and has been subjected to serpentine and chlorite alteration. Fresh, it is black-green in colour containing 70-80% pyroxene and amphibole with 20-30% interstitial plagioclase.

Trending at 100° to 110° with subvertical dips, several 2-10 meter thick quartz-feldspar and feldspar porphyry dikes have intruded the ultramafic flows over the very north of the grid between lines 3E and 6E. The dikes pinch and swell irregularly along their lengths. Typically weathering pink or white and being grey or pink when fresh, the feldspar porphyry dikes contain 20-30%, 2-5mm diameter, euhedral K-spar phenocrysts in a fine-grained matrix hosting 10-15% biotite and/or amphibole and up to 2% disseminated pyrite. Quartz-feldspar porphyry dikes are descriptively similar to the feldspar porphyry variety with the exception that they host up to 20%, 2-4mm diameter, quartz eyes.

The diabase is primarily exposed as a north-south trending 35-100 meter thick dike coincident with line 6E. A faulted off portion of this dike was located between lines 4E and 5E. Diabase also outcrops 60 meters east of line 12E at the baseline. It is a brown weathering massive, moderately magnetic unit that is green-black in colour when fresh. Normally, medium grained, the diabase is composed of 40% subhedral pyroxene ± hornblende, 60% euhedral plagioclase grains and trace amounts of disseminated pyrite. Locally, it is epidote altered along fractures.

Centered on line 5W at the baseline and line 8E at 1+50N, Cobalt Group sediments occur as interbedded conglomerates,

argillites and siltstones. Argillites are distinguished from the siltstones by their fissile nature. Conglomerates are polymictic containing up to 70%, but more commonly, 40-50% surrounded to rounded granitic, mafic volcanic and felsic volcanic clasts in a silty dark grey matrix.

Quaternary Geology

Ninety five percent of the grid area is overlain by unconsolidated Quaternary deposits. Glaciolacustrine clay and silt are the dominant deposit type, covering approximately 70% of the area (Lee 1979) Subordinate peat and organic terrain overlies the glaciolacustrine sediments. Outcrop areas on the north-central grid region are covered by C horizon soil or a thin veneer of till. Gravel, sand and silt deposits overlie the logged regions on the southwest of the grid. A north-northeast trending 100-150m wide, 3-5 meter high ridge of gravel, sand and clay is coincident with lines 6E-8E between 0+50N and 5+50S. The ridge may be an esker landform. In many instances a thin layer of basal till is present along the overburden-bedrock interface. Overburden has an average depth of 6.5 meters. Glacial material is believed to have been transported from north to south (Pyke, 1970).

Structural Geology

Ultramafic units consistently strike a 040°-050° with dips of 070°-085° to the south. The mafic to intermediate volcanics on line 12E have strike directions of 110-180° with dips of 060-070° to the south. A well developed schistosity of 020-040°/80°E crosscuts the intermediate-mafic volcanics. Top directions for both the mafic-intermediate and ultramafic volcanics is to the south.

The diabase dike, in the north central grid area, appears to have been offset by a N.N.W. trending fault in a right lateral sense. Elsewhere, north-south faulting is suspected between lines 4E and 5E, where the east-west trending porphyry dikes abruptly terminate.

Cobalt sediments, located at line 8E-2+00N have beds striking W.N.W. with dips of 50° to the north. A well developed N.W. striking, steeply north dipping cleavage overprints the bedding. The sediments centered on line 5W at the baseline have southeast striking beds with dips of 030-045° to the south.

Economic Geology

North-south trending quartz veins which are hosted in the felsic porphyry dikes on the north central grid area,

contain up to several percent pyrite. Surrounding the feldspar porphyry dikes, over a 150 by 300 meter area, is a well developed carbonate-talc-serpentine alteration halo in the ultramafics. Vein zones, which consist of 10%-30% quartz veins, are typically less than 2 meters wide and 10 meters long. Although the quartz vein zones are interesting, the large amount of work done on them by the Porcupine Miracle Mining Co. Ltd., between 1912 and 1915, and their subsequent negative results, indicate that gold mineralization is absent. No indications of economic mineralization were observed elsewhere on the property.

Results of Till Identification

Drill logs, detailing the types of overburden encountered, were completed by drill contractor personnel while drilling was underway. These logs are presented in appendix I at the back of the report. Most holes initially encountered 0.1 to 0.2 meters of organic material followed by a variable thickness of either clay, silt and sand or gravel, sand ± silt horizons. Basal till was normally encountered 1.0 to 0.2 meters above the bedrock-overburden interface. Many of the overburden drill logs failed to identify basal till in the holes. Subsequent examination of the +5 mesh size fraction, indicated that more basal till samples are present than were previously recognized. C horizon soil was

sampled at several locations, where there was only thin cover. The depth of overburden varied from 0.0 to 17.4 meters having an average of 6.5 meters.

Results of +5 mesh Clast Identification

Major and minor clast lithology types along with overburden depth, number of clasts and sample type are presented on Map 1 at the back of this report.

Clast lithology identifications failed to identify the causes of the conductors. Major lithologies identified included; ultramafic volcanic flows, mafic volcanic flows, intermediate volcanic flows and tuffs, porphyritic and equigranular monzonite, diabase and Huronian Cobalt Group, siltstone, and sandstones. Lithologies occurring in minor amounts include; granodiorite, Huronian conglomerate and argillite, vein quartz and vein quartz-carbonate.

Intermediate tuffs were recognized at only one location during bedrock mapping but occur frequently in till samples obtained from lines 6W and 7W. They are light green coloured, weakly banded, moderately schistose units that host 5%-30% subrounded to subangular 2-7mm diameter fragments in a fine grained matrix. The tuffs are weakly chlorite ± sericite-carbonate altered and on occasion host up to 2% disseminated pyrite as euhedral grains. Associated with the tuffs are mafic to intermediate volcanic flows.

Huronian sediments often have a well developed cleavage in them that is transposed onto their bedding. Sandstones occur as arkoses, quartzose arkoses and greywackes.

Ultramafic volcanics have undergone variable degrees of serpentine, carbonate and rarely talc alteration.

Samples taken on line 6W and 7W are suspected of being primarily derived from mafic to intermediate volcanic, monzonite and Huronian sediment bedrock. Those samples obtained on lines 6E and 8E mainly consist of ultramafic volcanic, diabase, Huronian sediment and monzonite clasts.

Heavy Mineral (+3.2 gm/cm³), -5 to +250 mesh Identification

Results of the heavy mineral identifications are presented in appendix II. No causes for the conductors were observed. Minerals consistently occurring in amounts greater than 5%, and listed in order of abundance are; pyroxene, magnetite, amphibole, epidote and garnet. Minerals occurring in minor amounts include; apatite, goethite, ilmenite, pyrite, sphene, tourmaline, zircon, hematite, biotite, leucoxene and chlorite. The relative amounts of the mineral types is primarily a function of their abundance in bedrock, up ice from the sample location, and their chemical and physical stability in the secondary environment.

The percentages of major minerals present remains relatively constant for all the till samples. Amphibole occurs

in amounts that are considered to be higher than is normally found in Archean terrains. No bedrock source for the elevated amphibole contents was found. Changes in the mineral contents cannot be reliably related to changes in the clast lithologies that were identified during the +5 mesh clast identifications.

Samples 6051 to 6054 have anomalous pyrite contents of 1% to 3%. Intermediate tuffs containing 2-3% pyrite in sample 6054 suggest a possible source for some of the pyrite.

Type of survey and number of Assessment days credit per claim	Mining Claims Assessed
Geophysical	
Electromagnetic _____ days	
Magnetometer _____ days	\$5331.00 SPENT ON OVERBURDEN DRILLING AND ASSAYING SAMPLES TAKEN FROM MINING CLAIMS:
Radiometric _____ days	P 758882-83-86-87
Induced polarization _____ days	779600
Other _____ days	780007
Section 77 (19) See "Mining Claims Assessed" column	
Geological _____ days	
Geochemical _____ days	
Man days <input type="checkbox"/>	Airborne <input type="checkbox"/>
Special provision <input type="checkbox"/>	Ground <input type="checkbox"/>
<input type="checkbox"/> Credits have been reduced because of partial coverage of claims. <input type="checkbox"/> Credits have been reduced because of corrections to work dates and figures of applicant.	

Special credits under section 77 (16) for the following mining claims

No credits have been allowed for the following mining claims

 not sufficiently covered by the survey insufficient technical data filed

The Mining Recorder may reduce the above credits if necessary in order that the total number of approved assessment days recorded on each claim does not exceed the maximum allowed as follows: Geophysical - 80; Geological - 40; Geochemical - 40; Section 77(19) - 60.

Mining Recorder
Ministry of Northern Affairs and Mines
60 Wilson Avenue
Timmins, Ontario
P4N 2S7

Dear Sir:

RE: Assaying submitted under Section 77(19)
of the Mining Act RSO 1980, on Mining
Claims P 758882, et al, in Langmuir and
Fallow Townships

The enclosed statement of assessment work credits
for assaying expenditures has been approved as of
the above date.

Please inform the recorded holder of these mining
claims and so indicate on your records.

Yours sincerely,

S.E. Yundt
