REPORT ON PROGRAMS CONDUCTED ON THE BEATTY - HISLOP TOWNSHIPS CLAIMS OF CANADIAN JOHNS-MANVILLE CO. LIMITED LARDER LAKE MINING DIVISION UNDER EXPLORATION ASSISTANCE CONTRACT KL-21 EFFECTIVE APRIL 42, 1972.

ЪУ

P. A. R. Brown and F. J. Evelegh

Exploration Dept. Canadian Johns-Manville Co. Limited

February 19, 1973 Matheson, Ontario.

APPENDICES

- APPENDIX I Property Plan of parts of Beatty and Hislop Townships on a scale of one inch equals 1000 feet, showing Company holdings outlined in red pencil.
- APPENDIX II Preliminary Geological Plan Showing Biogeochem Contours on a scale of one inch equals 50 feet as compiled by P. Brown.
- APPENDIX III Geological Report dated July 2nd, 1972 by J. H. Morris. Detailed Geological Plans -Sheets 1, 2, 3 and 4 - on a scale of one inch equals 50 feet, Index and Structural Elements Map and the Detail Geological Plan - Areas A, B, C both on a scale of one inch equals 400 feet and Legend Sheet accompany this report.
- APPENDIX IV Rock Descriptions by P. Brown and J. H. Morris. Bondar-Clegg & Company Limited Lab. Reports -385-2 (2) and 483-2.

Note that rock sample locations and analyses have been shown on the detail plans of Appendix III.

- APPENDIX V Geo-Magnetic Contour Plan on a scale of one inch equals 400 feet.
- APPENDIX VI Electromagnetic Profile Plan on a scale of one inch equals 400 feet showing results of the initial R. E. M. survey. Detailed Geological Plans - Sheets 2, 3 and 4 on a scale of one inch equals 50 feet showing R. E. M. check and MS-1000 electromagnetic profiles. Locations and analyses results for rock samples collected over zones of interest. Rock descriptions by P. Brown and Bondar-Clegg and Company Limited Lab. Report No. 1093-2.
- Appendix VII Field Sheets and P. H. M. C. descriptions for auger basal till samples. Bondar-Olegg & Company Limited Lab. Reports -613-2, 700-2 and 964-2 (2). Flan Showing Auger Basal Till Sample Locations and Geochem Analyses Results on a scale of one inch equals 400 feet. Flans (3) Showing Auger Basal Till and P. H. M. C. Sample Locations on a scale of one inch equals 10 feet.

APPENDIX VIII - Biogeochem Field Sheets dated April 13 to 17, May 10 to 16 and July 24, 1972. Bondar-Clegg & Company Limited Lab. Reports - 300-2, 301-2, 437-2 and 700-2. Cumulative Frequency Distribution Diagrams for Cu - Mo - Zn in alder trees. Biogeochem Sample Location Maps on a scale of one inch equals 400 feet for both Beatty and Hislop Townships. Contoured Biogeochem Survey Plans on a scale of one inch equals 400 feet for Cu, Mo and Zn in Beatty and Hislop Townships.

REPORT ON PROGRAMS CONDUCTED ON THE BEATTY - HISLOP TOWNSHIPS CLAIMS OF CANADIAN JOHNS-MANVILLE CO. LIMITED LARDER LAKE MINING DIVISION UNDER EXPLORATION ASSISTANCE CONTRACT KL-21 EFFECTIVE APRIL 44, 1972.

Introduction:

1

The following and enclosed reports describe the Exploration Programs carried out on the Beatty-Hislop Townships claims which form part of Contract KL-21, dated May 8th, 1972.

Initially thirty-one claims were staked by Company personnel during the latter part of February with the recording date being March 3rd, 1972. Posts were pretagged and claims numbered 333431 to 333433 inclusive, 339635 to 339642 inclusive, 339801 to 339819 inclusive and 339938. As shown on the accompanying Property Plan these holdings are not contiguous but are in scattered groups in Lots 1 to 5, Concessions 1 and 2, Beatty Township, and Lots 1 to 3, Concession 6, Hislop Township.

The north one-half of Lot 3, Concession 1, Beatty Township being 160 acres, was purchased outright (surface and mining rights) from the Corporation of the Township of Black River-Matheson on April 11¹⁰, 1972. This block was added to Contract KL-21 at that time.

Exploration programs conducted during the period of the Agreement, which are described in this and the attached reports, include line cutting, chaining, rock trenching, preliminary and detailed geological mapping, rock and soil geochemical surveys, biogeochemical surveying, R. E. M. and MS-1000 electromagnetic surveying and a magnetometer survey. Note that all work, both field and office, was carried out by Company personnel based at Matheson, Ontario.

Line Outting and Chaining:

A base line was started from a point on the boundary between Lots 3 and 4, Concession 1, Beatty Township, at a point 10+50 feet north of the No. 4 post of claim 339803 and extended to the east for a length of 2,600 feet on a bearing of N88°E. The base and right-angled offset lines were turned off using a transit. Picket lines, spaced at 200 foot intervals, were cut to both the north and south of the base line to cover the main outcrop area. Pickets were established at 100 foot intervals along all lines by chainage. Picket lines were tied in along their extremities by chaining to increase the accuracy of the plans.

2 .

During the course of this initial program 0.5 miles of base and 6.8 miles of picket lines were cut and chained.

Line cutting was extended to the east during the latter part of June preparatory to a detailed magnetometer survey to delineate the contacts of the diorite sill. A second base line, bearing due East, was started from a point on line 26+00 East at 11+50 feet south of base line No. 1 and out to the east for a length of 2,600 feet. Right-angled offset lines were again established at 200 foot intervals along this base line.

During the course of this second program 0.5 miles of base and 1.7 miles of picket lines were out and chained.

Details re man days worked and wages paid are shown in the following table. Costs with attached receipts are also listed.

Employee	Dates Worked 1972	Total 8- Hour Days	Daily Rate	Total Wages
J. Goodger	Apr 17-20 incl;24-27 May 1 & 2; June 27 &		\$30.13	\$ 361.56

Preliminary Geological Mapping and Prospecting:

These programs were carried out by P. Brown, geologist with this Company, assisted by R. Haley and M. Bruce. Field work was concentrated along the porphyry and diorite contacts and over biogeochemical Cu - Mo anomalies.

Rock trenching, mapping and sampling which in part were conducted concurrently with the preliminary prospecting and mapping program, are discussed in other sections of the report.

The results of this initial survey are discussed on the following five pages under the heading "Preliminary Report on Beatty Township" compiled by P. Brown and dated June 5%, 1972. This report is accompanied by a "Geological Plan Showing Biogeochem Contours" on a scale of one inch equals 50 feet. The boundaries of this preliminary map sheet have been coloured green and are shown on "Index and Structural Elements Map" on a scale of one inch equals 400 feet. (See report by J. H. Morris)

Details re man days worked for both field and office phases of the project and wages paid are shown in the following table; -Note that receipts for other costs incurred are attached.

Employee	Dates Worked 1972	Total 8- Hour Days	Daily Rate	Total Wages

PRELIMINARY REPORT ON BEATTY TOWNSHIP

Location and Accessibility:

Beatty Township is located in the Larder Lake Mining Division immediately northeast of Matheson. The property under investigation is in the N1/2 of Lot 3. Access is readily gained by driving east from Matheson for about 7 miles to the Holtyre turnoff, then walking north for three-quarters of a mile on a good trail, which was a former bush road, to the Stewart-Abate property. At this point the property lies 250 feet immediately to the east.

Topography and Vegetation:

The area comprises low lying, ice scoured outcrops surrounded by swamp. The soil beneath the swampy areas is clay and sand laid down during glacial lake times. Vegetation is mainly poplar, alder and spruce with minor balsam and birch.

General Geology:

Rocks in the area are Precembrian with pleistocene sand and clay cover. The Table of Formations is shown below: -

Pleistocene - sand and gravel

Lamprophyre Feldspar porphyry Dioŕite

Sediments - greywacke, quartzite (argillite ?)

Sediments:

Quartzite is the most common sedimentary rock followed by greywacke. Argillite may be present but as yet not mapped. The quartzite varies from a light green regular quartzite through greenish-grey into definite grey greywacke. Pyrite is a common constituent in these rocks making up 10% of the whole in places. Bedding is well marked and strikes are relatively easy to determine. Where the quartzite is greyish, small quartz eyes are common, being about 1/16" in size.

Carbonatisation and sericitisation are present in some areas and are thought by J. Satterly and H. S. Armstrong of the Ontario Dept. of ^Mines, 1947, to have occurred just after the emplacement of the lamprophyre with the solutions being derived from the same magma that gave rise to the Algoman porphyries.

Diorite (?):

One diorite intrusive ? cuts across the N1/2 of Lot 3. Generally it is sill-like being roughly parallel to the strike of the sediments. At the Stewart-Abate property it obtains a width of 200 feet. Joints are abundant and cross fracturing is common, together with small quartz veins.

Felspar Porphyry:

A small plug intrudes the sediments in the NE 1/4 of the N 1/2 of Lot 3 with several smaller bodies around it. The main body varies in composition from west to east being more acidic in the east. Grain size is variable but generally the felspars may reach 1/2" and a distinct zoning can be seen. The NW quarter of the plug contains abundant inclusions of sedimentary rock and possibly partially digested volcanics. Jointing is fairly common but not as distinct as in the surrounding sediments. Practically all the porphyry has suffered carbonatisation and sericitisation. Accessory minerals include pyrite, chalcopyrite, molybdenite, and hematite making the weathered rock a bright rusty colour.

Lamprophyre:

This is the youngest rock type in the area and has two prominent directions - a) parallel to the strike of the sediments; and b) parallel to the main direction of the faulting. (i.e. N30°E) In places carbonate is present as small veins. Generally these rocks have rounded inclusions of country rock and large biotite books, the whole being extremely hard. Fractures parallel to these dykes are present in the country rock.

Faulting:

The major faulting direction is N30°E and the movement is apparently rotational. Carbonate, quartz, or quartz and carbonate are present along these fault planes. Sulphides may or may not accompany the quartz and carbonate. In the northeast corner a 3 inch carbonate vein was found just south of the beaver pond along a fault. Chalcopyrite is abundant here.

Mineralisation:

Economically the main mineral of interest is molybdenite which is abundant. Other minerals present include chalcopyrite, galena, sphalerite, pyrite and hematite. Gold may be present but is not expected to be visible in hand specimen due to the extensive blasting carried out during the early 1900's.

Disseminated molybdenite has been found in the more acidic phase of the main plug on lines 18+00E and 20+00E at about 4+00N. Generally, the molybdenite is very fine grained but occasionally tight joints may be opened and crystals up to 1/8 inch can be seen on faces covering about 30% of the area.

In general areas of high molybdenite have suffered carbonate alteration.

Seams and disseminations ? of molybdenite are found throughout the sediments and diorite coinciding with the biogeochemical anomalies and this covers a significant area (4½ million square feet). The seams are tight joints and may have from 10% to 98% MoS2 on the surfaces. This is especially noticeable in the quartzite just west of line 14+00E at 7+00S.

Chalcopyrite has been found in the central area of the anomalous molybdenite zone and also close to the conductors detected by the E. M. survey. Amounts found are minor and generally associated with an equal or greater amount of pyrite.

Galena and sphalerite were found in an altered phase of the diorite associated with carbonate veins. A small blast has been made at 12+20E, 2+50S which exposes the minerals.

Some galena (very minor) was found associated with chalcopyrite and pyrite about 200 feet to the southeast (14+00E, 4+00S).

Conclusions:

- 1. Molybdenite mineralisation is associated with the intrusive felspar porphyry.
- 2. Major concentrations of molybdenite are found where fracturing and quartz veining is present.
- 3. Minor chalcopyrite is associated with some quartz veins usually with pyrite but not often seen with the molybdenite.
- 4. Fyrite is abundant throughout the sediments and porphyry.
- 5. The biogeochemical survey has effectively outlined the surface molybdenite showings.
- 6. The electromagnetic survey has located conductors, and sulphides have been found at these locations.
- 7. The magnetometer survey has traced the diorite under overburden and outlined the altered phases in the centre of the area.
- 8. The absence of molybdenite in the centre of the plug may indicate some form of zoning.

- 8 -

Recommendations:

- Blasting of tightly jointed areas should be carried out a) to break up the rock, and b) to get below the weathering effects.
- 2. An estimation of amount of jointing should be obtained.
- Observations to see if the molybdenite is related to any specific set(s) of joints or fractures.
- 4. Observations to determine if zoning of pyrite, molybdenite and chalcopyrite exists and can be related to a porphyry-type deposit.

5. Assaying.

Summary:

The small isolated outcrops of felspar porphyry may be connected at depth into a larger pluton.

In this case the low biogeochemical values for the centre of the large plug may be due to erosion down to the low grade core of a porphyry-type zoned deposit.

Overall the area has considerable promise in making a low grade molybdenum deposit.

Detailed Geological Mapping:

This program was conducted by J. H. Morris, geologist, assisted by T. DeMarchi. Both field and office work were completed by these two employees. Note that J. H. Morris was hired for the 1972 field season and is now attending the Graduate School, Dept. of Earth Sciences at Waterloo University.

A copy of the "Geological Report on the Beatty Township Claims" compiled by J. H. Morris, complete with detailed geological maps and dated July 2nd, 1972 is attached.

Details re man days worked for both field and office phases of the project and wages paid are shown in the following table. Note that receipts for other costs incurred are attached.

Employee	Dates Worked 1972	Total 8- Hour Days	Daily Rate	Total <u>Wages</u>

		Tota	1	\$1.713.89

Rock trenching was carried out as part of the geological program at locations selected by P. Brown and later by J. H. Morris. The purpose of this work was to expose fresh surfaces for geological mapping and rock sampling. Trench and pit sites have been shown on the Geological Plans - Sheets 1, 2, 3 and 4 - on a scale of one inch equals 50 feet. Mineralization in these pits is discussed by J. Morris in his report under the heading "Economic Geology" (See

- 10 -

Appendix III).

A gasolene-powered Copco plugger was used for this work which was conducted by the Company personnel listed in the following table;

Employee	Dates Worked 1972	Total 8- Hour Days	Daily Rate	Total <u>Wages</u>

In Appendix IV find detailed descriptions of rook samples numbered BE-1 to BE-14 inclusive, collected from outcrops and pits by P. Brown during the course of the preliminary mapping and prospecting program. Only samples 1, 2, 4, 6, 7 and 12 were analyzed geochemically. The results are shown on Bondar-Clegg & Company Limited Lab. Report No. 385-2 - sheets dated May 26ª and June 1st, 1972. All samples were analyzed for Fe and Mo - two samples were tested for Cu. With the exception of sample BE-7, which contained 1820 ppm Mo, all results were non-anomalous.

Also included in Appendix IV find descriptions of samples BR-1, 2 and 3 collected by J. H. Morris. These three samples were analyzed geochemically for Cu, Mo, Ag and Au and the results are

- 11 -

shown on Lab. Report No. 483-2. Sample No. BR-2, which contained 700 ppm Cu, 1400 ppm No and 50 ppb Au, is of interest.

Note that rock sample locations and analyses have been shown on the detailed geological maps - Sheets 1, 2, 3 and 4 on a scale of one inch equals 50 feet which accompany the report compiled by J. H. Horris (see Appendix III).

Magnetometer Survey:

A magnetometer survey was completed on the grid of base line No. 1 during the latter part of April by G. Edwards, geophysical operator with this Company. The grid of base line No. 2 was surveyed by J. Goodger, geologist, on June 29th, 1972. Magnetic readings were recorded using a Jalander type instrument (Serial //NR 57133) having sensitivities of 11.0, 32.3, 111.0, 335.6 and 1146.0 for scales 1, 2, 3, 4 and 5 respectively.

As standard Company procedure this instrument was checked on Munro Mine Base Station No. 2 (Munro-Beatty Sill) prior to the survey and an adjustment made so that a gamma value on the Jalander of 1220 corresponds to an absolute value of 57,599 \pm 15 gammas. This has been previously established at the Government Magnetic Base Station at Matheson.

One base control station was used for the survey and is located on picket line 4+00 East at 0+30 feet north of base line No. 1. This station has a fixed value of 1620 gammas and readings were recorded at approximately four hour intervals as a check on the working condition of the instrument and to record the daily diurnal variation.

Stations were spaced at 50 foot intervals along the offset lines and a total of 899 was recorded on the block. Miles traversed - 8.5.

- 12 -

The results of the survey are shown on the accompanying "Geo-Magnetic Contour Plan" on a scale of one inch equals 400 feet. Magnetic values have been contoured at 500 gamma intervals from 1000 to 4000. Note that the picket line grids and magnetic values have been superimposed on an enlargement of Map No. 1947 - 2, Township of Beatty as published by the Ontario Dept. of Mines.

As anticipated, magnetic intensities over the sedimentary rocks and porphyry intrusive are weak and relatively uniform. Readings range in value from slightly less than 1000 to 1800 gammas in close proximity to the contacts of the diorite sill. In general, values fall in the range of 1100 to 1300 gammas.

Readings over the southeasterly trending, south-dipping diorite sill range in value from 1800 gammas along the contacts to 4800 gammas over bedrock exposures in the central part of the 200 foot thick intrusive. As shown on the accompanying plan, there is excellent correlation between J. Satterly's geological contacts and magnetic values in outcrop areas. Minor discrepancies occur in overburden-covered sections where magnetic data indicates the contact to be farther to the north (i.e. lines 22+00E to 30+00E, inclusive).

The northeasterly striking fault pattern, shown by Dr. Datterly, has been sharply defined by the magnetic survey. Additional cross structures, indicated by the recent work, have been shown in red pencil on the Geo-Magnetic Contour Plan.

Magnetic surveying was carried out on the property to delineate the contacts of the diorite sill and any offsetting cross structures. As described in the next section of this report, these contact zones will then be explored for sulphide mineralization using electromagnetic surveying methods.

- 13 -

Details re man days worked and wages paid are shown in the following table;

Employee	Dates Worked 1972	Total 8- Hour Days	Daily Rate	Total Wages
G. Edwards	April 27, 28, 29; Nay 2 and 3	5	\$24.30	\$121.50
J. Goodger	June 29	1	\$30.13	30.13
2	Totals	6		\$151.63

Electromagnetic Survey:

Electromagnetic surveying was carried out on the Beatty Block in four separate stages as described in detail in the following paragraphs.

Initially the grid of Base Line No. 1 was surveyed using a McPhar R. E. M. vertical loop unit applying the "in-line" method. Distance between transmitter and receiver was maintained at 200 feet during the course of this work. Walki-talki units were used for communicating field data. Stations were spaced at 100 foot intervals.

The grid of base line No. 2 was surveyed in the same manner using the identical equipment. R. Haley, geophysical operator with this Company, conducted both surveys. R. Hallock assisted with the initial program which was completed in the early part of May. Note that W. Foster helped with this work. T. DeMarchi assisted on the second survey - completed in the latter part of June.

Results of these two surveys are shown on the accompanying "Electro-Magnetic Profile Plan" on a scale of one inch equals 400 feet. Profiles have been plotted on a scale of one inch equals 20°. Conducting zones have been marked in purple dashes.

Three weak conductors have been delineated by the R. E. M. "in-line" survey. Dip angles for the zone in the sediments to the

- 14 -

north of the base line on picket line 16+00E, crossover from +1° to -1°. Dip angles are of the same magnitude for the conductor along the north contact of the diorite sill on lines 16+00E and 18+00E. On line 12+00E along the east side of an outcrop of altered sediments, a crossover having dip angles of $+2^{\circ}$, -1° , was recorded. Very minor pyrite, chalcopyrite and molybdenite mineralization was noted in narrow quartz stringers in this bedrock exposure.

As the conducting zones could be indicative of low percentage of disseminated sulphides detailed R. E. M. surveying was carried out over the previously delineated conducting zones. This work was carried out by F. Brown, geologist with this Company, assisted by J. Goodger and T. DeMarchi and was completed during the early part of October, 1972.

The results of the original in-line, re-read in-line and transmitter set-up surveys have been superimposed on the detailed Geological Plans of J. H. Norris - scale one inch equals 50 feet -Sheets 2, 3 and 4. Note that to emphasize minor changes the profiles have been plotted on a scale of one inch equals 5°. A brief report compiled by P. Brown, covering this check work, is shown on the following page.

- 15 -

REPORT ON R.E.M. CHECK SURVEYS BEATTY BLOCK, BEATTY TOWNSHIP

16 -

Five conductors (weak) were indicated from the original survey carried out early in 1972.

The object of the latest survey was to detail the R. E. M. conducting zones with transmitter set-up method using both the 1000 cps and 5000 cps frequencies.

Detailing was carried out around the indicated crossover on line 18+00E at 9+00S. This work did indicate a weak conductor but it did not pick up anything on line 18+00E. Thus checks were run on all the indicated conductors using the 1000 cps, 200' coil spacing as had been carried out originally.

Results were disappointing since none of the indicated conductors checked out. Line profiles are generally similar but do not give "crossovers".

Samples were also collected from these original crossover points (or close to) except for the one on line 16+00E, 5+00S since no outcrops occur close by and depth to rock is probably 5 to 10 feet.

Insufficient sulphide (conductive material) to give a conductor using the R. E. M. unit was observed at all locations.

Submitted by: P. A. R. Brown October 134, 1972

cc: H. K. Conn file As part of this detailed R. E. M. program a series of selected rock samples were collected over the original conducting zones and shipped to Bondar-Clegg & Company Limited for geochemical analyses. The seven samples numbered BR-1 to BR-7 inclusive have been described by F. Brown and these descriptions are included in Appendix VI.

Analyses are shown on Geochem Lab. Report No. 1093-2 dated October 31, 1972. The results have been plotted on the 50 scale detailed Geology Sheets 2, 3 and 4 which show R. E. M. profiles see Appendix III. Individual samples contain up to 1000 ppm Cu and 1100 ppm No - well below ore grade.

Due to the occurrence of minor disseminated chalcopyrite and molybdenite mineralization in outcrops adjacent to the original conducting zones, a final electromagnetic check survey was carried out to further test zones of interest. This program was conducted by P. Brown during early January, 1973 using a MoPhar MS-1000 deep penetration, vertical loop electromagnetic unit.

The results of this survey have been plotted on Geological Sheets 2, 3 and 4 on 50 scale which show R. E. M. profiles and rock geochemical data. Note that profiles for the MS-1000 work are on a scale of one inch equals 5°. As indicated on the results no conducting zones were delineated by the deep penetration survey.

Details re costs, with attached receipts, and man days worked for all of the electromagnetic programs - both field and office - are as follows; -

Geochemical Soil Surveys:

Samples of basal till were collected over biogeochemical anomalies and weak electromagnetic conducting zones on the Beatty Block using a hand auger. Company personnel conducted this work.

Locations of all samples and analyses results are shown on the accompanying Flan on a scale of one inch equals 400 feet. Maps showing exact sample locations are also included. These three sheets are on a scale of one inch equals 10 feet. Field sheets giving sample descriptions, etc. and Bondar-Clegg & Company Limited Lab. Reports are also part of Appendix VII.

Initially, samples were collected over anomalous Cu - Mo biogeochemical zones and all of the material was shipped to Bondar-Clegg & Company Limited for analyses. The twelve samples, numbered B-1000 to B-1011 inclusive were tested for Cu and No and the results are shown on Lab. Report No. 613-2. With the exception of one organic sample which contained 470 ppm Cu, results were of little interest.

The second phase of the program consisted of sampling the basal till over conducting zones on a 10 foot grid system. Again, all of the material was sent for analyses. These twenty-five samples, numbered C-1000 to C-1024 inclusive were tested for Cu - Mo - Pb and Zn and the results are shown on Lab. Report No. 700-2. Although several weakly anomalous analyses were obtained same are of little importance re economic sulphide mineralization. Note that a value of 54 ppm Zn was obtained from a sample site in Block "D" - the highest Zn value in the area sampled.

As a final check, soils over four of the conductors were

- 19 -

resampled, then concentrated by panning and the panned concentrates analyzed for Cu - No - Pb - Zn and Au. These fourteen samples were numbered C-1025 to C-1038 inclusive and the results are shown on Lab. Report No. 964-2. Values, in general, were weak, however, one sample in Block "F" (adjacent to narrow quartz stringers in the diorite) contained 2000 ppb Au. It is of interest to note that concentration improved the 54 ppm Zn in Block "D" to 290 ppm.

Details re man days worked and costs are shown in the following table; - Receipts are attached.

Biogeochemical Survey:

Biogeochemical surveying, which consisted of sampling second year stems of alder trees - a few spruce were used where alders were not available - was carried out in three stages on the Beatty Block. Geologists and senior fieldmen conducted the field work.

Trees were sampled during the mid part of both April and May and on July 24m as shown on the Field Sheets. Bondar-Clegg & Company Limited Lab. Reports numbered 300-2, 301-2, 437-2 and 700-2 are also included in Appendix VIII. Samples were closely spaced along the south contact of the porphyry body and were analyzed geochemically for Cu and Mo. Bamples were spaced at 400 foot intervals along claim lines on the remainder of the group and were tested for Cu, Mo, Pb and Zn. (See the accompanying Biogeochem Survey Plans in Appendix VIII).

The twigs are taken using pruning shears from branches distributed as evenly as possible about the tree and placed in a numbered sample bag. A piece of flagging tape with the sample number is tied to the tree for future reference and data is recorded pertaining to the sample. Field sheet records include date, weather, name of sampler, project number, location, sample number, topography, drainage slope, tree type and size of tree.

To prepare the biogeochem samples the plant material is put through a Wiley Mill and reduced to -1 mm. A 20 cc. crucible is filled with material and total weight recorded to three decimals. Drying in a vented oven for two hours at 105°C followed by a second weighing is the next step. Another drying for one hour is carried out and if the resulting weight compares with the second weighing then the sample has reached constant weight and is consid-

- 21 -

ered dry. This dry weight is also recorded.

Charring is the most important stage and is critical. Resins are burnt off but free carbon must not be produced. This is done in a muffle furnace with the door open for two hours at about 200°C. These conditions are variable depending on the material. The furnace door is now closed and the temperature increased to not more than 450°C. When a clean white or slightly grey ash with no black material remains then the sample is taken out, placed in a desiccator and when cool brushed onto a balance pan. Its weight is recorded to three decimals. The ash is now digested for onehalf hour by 1.5 cc. of concentrated nitric acid in a test tube of 90°C, controlled by a water bath. Then 1/2 cc. of concentrated hydrochloric acid is added and digestion continued for one and onehalf hours. The tube is then removed and the sample diluted to 10 cc's with de-ionized water. The contents are shaken to mix and allowed to settle. Metal concentrations are read by Atomic Absorbtion and calculated to ppm based on the original ash weight.

Overall accuracy for Cu, Mo, Pb and Zn is a maximum of 20% relative standard deviation which is acceptable.

Extraction of essential information is carried out statistically and is best done by graphical representation of the frequency distribution of the data; then the average value (background) degree of variation and the existence of one or more populations is precisely determined.

The distribution pattern which best fits geochemical and biogeochemical data is the lognormal one. Graphically this gives a bell-shaped curve which when smoothed gives the frequency curve. Then plotting the cumulated frequencies as ordinates the cumulative

- 22 -

frequency curve is derived. This is the integral of the frequency curve. By replacing the arithmetic ordinate scale with a probability scale the cumulative frequency curve is represented by one or more straight lines.

Fifteen to twenty-five classes are recommended and as a rule the width of a class, expressed logarithmically, must be kept equal to or smaller than the standard deviation.

Cumulative frequency distribution diagrams have been compiled for Cu, Mo and Zn in alder trees. These diagrams are included in Appendix VIII and are discussed in the following paragraphs; -

All samples were analyzed for Cu and Mo. Some of these were also tested for Zn and a few for Pb. Note that 575 determinations were made - 236 for Cu, 236 for Mo, 87 for Zn and 16 for Pb. In addition 91 checks were made on Mo results and 3 checks on high Zn values.

Most of the black spruce were not sent for analysis but are stored at the Matheson office for future reference. Results for the few samples shipped seemed to be low and analysis of the spruce was not considered warranted at the time.

Contour maps have been prepared for Mo, Cu and Zn. An insufficient number of results were available to compile a cumulative frequency distribution diagram for Pb.

Mo in Alder:

The cumulative frequency distribution is lognormal indicating one homogenous population and one origin. Values range up to 1900 ppm with background at 47 ppm. Anomaly contrast is high with the threshold at 550 ppm giving a value from almost 12 to 40. Standard deviation (b + s) is 165 ppm.

- 23 -

It is interesting to note that the contour map fits well with field observations. Finely disseminated or thinly coated slip faces of Mo can be found in the probably anomalous areas and really good samples with thick flakes are readily obtainable in the anomalous area to the east of the shaft.

Ou in Alder:

The cumulative frequency distribution shows close to lognormal distribution with background (b) at 425 ppm, (b + s) 575 ppm and threshold (t) at 775 ppm. Anomaly contrast is low with a maximum of 3. The contour map shows an interesting anomaly on claim 339640. This is coincident with the Zn anomaly and further follow-up should be carried out here.

Zn in Alder:

The normal distribution (straight line) is altered by the presence of a highly anomalous population deviating from the norm at 4400 ppm. This concerns 10% of the population. Background is 2700 ppm, (b + s) 3950 ppm and (t) 5700 ppm. Anomaly contrast is about 2 ranging up to 8 times background which is high for Zn making the anomaly on claim 339640 of great interest.

Pb in Alder:

There were 16 samples analyzed geochemically for Pb. Results vary from 255 ppm to 580 ppm. No correlation can be seen between these and the Zn results and no map has been made for this element.

Details re man days worked, labour and miscellaneous costs for the biogeochemical program are shown in the following table. Receipts are attached. Note that both field and office work have been included.

Total expenditures by Canadian Johns-Manville Co. Limited under the Bestty Block portion of Exploration Assistance Contract KI-21 = \$9,412.75.

Refundable portion totals - \$3,137.58.

Overall Conclusions and Recommendations:

The results of the detailed exploration programs conducted on the Beatty Block of claims have failed to reveal any economic chalcopyrite - molybdenite mineralization within or along the contacts of the porphyry body. However, as sparse mineralization has been mapped to the south of the porphyry, the possibility of the occurrence of an exocontact deposit at depth still exists. In this respect, an I. P. survey is recommended for the north one-half of Lot 3 in Concession 1. Work should be carried out after the breakup period in 1973 using the Company unit, if available. Otherwise the survey should be contracted to Scintrex.

GEOLOGICAL REPORT

BEATTY TOWNSHIP CLAIMS

by

J. H. Morris

Exploration Dept. Canadian Johns-Manville Co. Limited.

July 2nd, 1972 Matheson, Ontario.

GEOLOGICAL REPORT -- BEATTY TOWNSHIP

Access and Topography:

Beatty Township is situated approximately four miles east of Matheson. Highway #101 from Matheson passes along its southern boundary with Hislop Township. Access to the main grid, situated in Concession 1, Lot 3, north half, is by way of a bush trail to the old Stewart-Abate property leaving Highway #101 approximately one mile and a quarter west of the Beatty-Mumro Township line. The positions of areas A, B and C relative to the main grid, are shown upon the index map.

The topography is low and gently undulating, swampy areas surrounding the sparsely vegetated outcrop areas. The swampy areas are either open or covered with fairly well spaced tag alder. Poplar and birch predominate in those areas neither swampy nor rock outcrop. The cover in such areas is very open with negligible undercover beneath the main canopy. Spruce and balsam mainly occur along the margins of swampy areas. All vegetation cover has developed since 1916, as this Township was involved in the great fire of Matheson of that year. The topography becomes much more hilly to the north (northern part of area B).

Previous Work:

Beatty Township was mapped by Satterly and Armstrong of the Ontario Dept. of Mines in 1944-45, the results of which were published in the Fifty-Sixth Annual Report, Part 7, 1947. Prior to that mapping of this Township was carried out in 1914, and other adjacent townships in 1911 and 1914.

Until recently gold was apparently the only object of prospecting and mimeral development in the Township. Within the area covered by our claims two old gold properties exist. Area A covers what was the Martin property (and upon which the Ontario Dept. of Nines report has no information), and area C covers what was the Denovo property. The Stewart-Abate property lies immediately to the west of the main grid (the shaft is approximately four hundred feet west of the western end of the base); the northeasterly extension of the ore structure lies within our claims, just to the north of the western end of the baseline. Visible gold, with molybdenite, chalcopyrite and pyrrhotite, was found upon the latter property. No significant gold values were found upon the Denovo property.

Within the area of the main grid, considerable trenching and pitting has been carried out, especially on line 14+00E at 10+00S, where a quartz vein up to four feet wide occurs. Two drill holes were also found. In area A some trenching has been carried out together with the sinking of an inclined shaft, approximately twenty-five feet deep. Trenches and pits in area B were to test pyritic gossan zones restricted to diorite dykes. Considerable trenching and pitting, together with diamond drilling, was carried out within area C, the old Denovo property. Two shafts were also sunk, both vertical, one to twenty-eight feet, the other to thirty-four feet. A few of the trenches are presumed to have been in search for mineralisation other than gold, as no possible goldbearing structures exist in their vicinity.

General Geology:

All basement rocks are Archaean, being metasediments (arenite, argillite), diorite, feldspar porphyry, lamprophyre and diabase/ gabbro. In the area of the main grid, covered by detailed mapping,

- 2 -

the metasediments predominate. A diorite sill two to four hundred feet in width, parallels the bedding of the metasediments, the strike which is approximately S70°E, with a variable dip to the south. Feldspar porphyry occurs predominantly as plugs, the largest of which occurs in the north central part of the grid; small dykes also exist. Certain areas are altered. A lamprophyre dyke, variable from one to twenty feet wide, strikes approximately east/west along the baseline. The youngest (?) Archaean rock present is a diabase dyke seen in area A. Pleistocene deposits are well developed in two areas, in area B and in the southeastern portion of Sheet 4; they are interpreted as glaciolacustrime and glaciofluvial respectively. Ice scoured rock surfaces are visible in a few areas. Recent deposits are represented by the development of peat bog and swampy areas.

Detailed Geology:

A) Lithologies. Archaean (in stratigraphic order)

(i) Metasediments. (1c, d)

These are composed predominantly of impure quartzite (arenite), with a lesser amount of well laminated to massive argillite/siltstone. Minor amounts of laminated chert (up to three feet wide) and intraformational conglomerate exist. The arenite is a dark grey, medium grained, massive rock; it is variable from siliceous (pure quartzite) to non siliceous where the matrix predominates, usually being intermediate between the extremes. Quartz grains occur as very small glassy "eyes", content being variable and so controlling the purity of the quartzite. Both this and the argillite are yellow when altered, either close to the diorite or to the feldspar porphyry. The argillite is a fine grained, grey, non siliceous

- 3 -

rock, normally well laminated, but occasionally massive. In places it becomes very siliceous, or even a yellowish-grey laminated chert. Intraformational conglomerate bands are best developed in Area B, bands being up to five feet wide and consisting of rounded tabular argillaceous fragments in an arenite matrix. Sedimentary structures seen include ripple marks, channel scours, slump folds, graded bedding (drill core, area C), and cross bedding (very rare as single units). Where seen, such structures indicate that the sediments face to the north, but are overturned and dip to the south. The general strike is S70°E, dip 70°S. Occasionally the arenite and argillite is gradationally interbedded and might be more properly termed greywacke. The metasediments are the predominant lithology in the area covered by the index map.

(ii) Diorite: 4a

The diorite occurs as a sill-like mass, variable in width from two to four hundred feet. It is normally mesocratic, with mafic and acidic minerals approximately equal, but may become melanocratic with the mafic minerals greatly predominating. Its texture is variable from coarse in the centre to fine grained, andesitic at its margins with the sediments. Disseminated pyrite is common as is magnetite on microjoints and within the rock. It cuts bedding at a very small angle and in two places includes the metasedimentary country rock.

(iii) Feldspar porphyry: 5c

This occurs mainly as small plugs and more rarely as narrow dykes. In its fresh state, it is a pinkish-white, leucocratic rock, with feldspar phenocrysts up to one quarter of an inch long. Mafic content is approximately 5%; some rusty weathering material (carbonate ?) is visible on weathered surfaces. Disseminated pyrite, haematite, and rarely molybdenite, is present. When altered, it becomes greenish-white with scattered green carbonate patches, weathering to a deep rusty brown. On line 18+00E, 7+00N, this alteration is prominent and very clearly related to a well developed foliation (sericitic/carbonate foliation planes). (iv) Lamprophyre: 5f

Possibly two dykes are present, the main one continuous (though offset by faults) from line 0+00 to 18+00E approximately along the base line. A second one, twenty feet wide and striking SW occurs on line 20+00E, 14+00S. Both are melamocratic, black to pinkish black, micaceous rock; it is darkest where the biotite is most prominent. Rounded xenoliths of both the metasediments and feldspar porphyry are common.

(v) Gabbro/diabase: 6a

This was noted in area A only and is presumed (from the Ontario Dept. of Mines map) to be the youngest Archaean rock seen. In the outcrop mapped, it is fairly fine grained, mesocratic, but immediately to the west occurs as a very wide porphyritic dyke (gabbro). (vi) Quartz diorite: 4a (seen in areas B and C; in the latter mapped as lamprophyre). Same age as diorite ?

In both areas these are narrow sills up to five feet wide. The matrix is greyish-white, fairly siliceous with scattered black mafic clots. Four such bodies were found, three in area B and one in area C. In all cases pyritic gossan is associated with seams and nodules in the sills; this is especially well developed in area B. In area C a quartz/carbonate stockwork has been developed predominantly perpendicular to the sill boundaries and discontinuous into the sediments. It is upon this sill that one of the Denovo shafts was sunk.

(vii) Pleistocene:

In area B, a series of shoreline berms, similar in form to a storm beach, are present along part of the southern margin of the hilly area in the northern part of this area. The Ontario Dept. of Mines report suggests that such a relationship was developed in glacial lake Barlow-Ojibway, the hilly areas at that time being islands with pebble beaches forming around them. This interpretation appears to be correct.

In the area covered by Sheet 4, a boulder bed of well rounded boulders up to four feet long is present. Both vegetation and soil cover is poorly developed, the boulders being exposed in many areas. This deposit is interpreted as glaciofluvial in origin.

B) Structural geology:

(i) Foliations:

Two cleavages are present, termed S_1 and S_2 respectively. Only in one place, line 13+00E, 8+00N, are the two seen together. Here S_1 is developed as a quartz filled fracture cleavage, lithons up to one inch wide; its general trend is SE, with a dip of approximately $60^{\circ}S$. S_2 is a much more prominent cleavage, lithons being less than 4 mm. wide; its general trend is NE, also with a dip to the south (shallower than S_1). As these foliations are present in feldspar porphyry, this indicates that it has undergone two recordable deformations. In the immediate vicinity S_2 is the predominant foliation, being defined by sericitic, altered surfaces (an overall greenishwhite appearance). Apart from two other places where S_1 was observed very poorly developed in argillite (area C and line 4+00E, 2+00N),

- 6 -

the only cleavage observed is S_2 ; it is found in all lithologies except the diabase/gabbro. It is only spasmodically developed. Where a "shear zone" (with or without quartz veining) such as that at the Stewart-Abate is developed, then S_2 and the "shear zone" are parallel in strike, though may be divergent in dip. (ii) Jointing:

Numerous readings were obtained with the purpose of seeing if any relationship existed between jointing and folding. This has not been done, but at least shows that joint sets (a complimentary joint set with an acute and obtuse angle) of specific orientation are developed in the metasediments and feldspar porphyry. Overall, all lithologies are well jointed, though the lamprophyre least of In the more siliceous rocks, such as chart, the effect of the all. numerous joint sets is to create a very hackly surface and breaking up into pieces less than one inch in size. As the rock becomes less siliceous, so the jointing becomes more spaced (pieces up to one foot long obtainable). The average size of a joint faced piece is generally one to four inches. It is stressed that joint set (of which there are many of different orientations) here means a complimentary set and not a series of high angle, sub parallel fractures, as found in the porphyry deposits of the southwest United States; hence no attempt was made to count fractures or obtain details of spacing, this appearing to be a function of lithology.

However, in two areas, line 16+00E, 1+50S and line 16+00E, 7+50N, prominent quartz veined fractures occur. In both cases feldspar porphyry is involved; in the former occurrence closely spaced (less than six inches) quartz veinlets in two directions

- 7 -

cut across the contact. This was the only place where such a relationship was observed. At 7+50N, the quartz veining is related to well spaced joints (average one to two feet apart), though the direction paralleling S_2 is more prominent.

(iii) Folding:

Two periods of deformation are recognised, D_1 and D_2 . Intersection of S_0 (bedding) and S_1 yields L_1 (lineation) which is synonymous with the fold axis of F_1 ; only two such lineations were obtained (area C and line 4+00E, 2+00N). Though opposite plunges were obtained (which is presumably a result of D_2 and faulting), both intersections indicate an anticline to the south. This would be in accordance with both the facing directions of the sediments and also with a synclinal structure mapped by the Ontario Dept. of Mines, the axis of which passes through Painkiller Lake in the northern part of the Township. It is suggested that F_1 consists of overturned folds plunging to the SE.

The second period of folding is indicated by the presence of S_2 . Only one intersection obtained (that of S_1 and S_2 giving L_2 i.e. the F_2 fold axis on line 18+00E, 8+00N) is strictly valid. All other intersections obtained (i.e. S_0 and S_2) can only approximate to L_2 as S_0 was no longer a planar element (having been folded by F_1) prior to F_2 . However, as S_0 has a well developed regional trend, the error involved is minimal (and also as the F_1 anticline is to the south, then S_1 , if a fan or axial planar cleavage, would have a shallower dip to the south than S_0). From these intersections, F_2 fold axes were obtained (see structural element map). In the grid area, the general trend is SW with a plunge of approximately 60° in that direction. In all cases, bar two, an antiform is indicat-

- 8 -

ed to the north (referred to as an antiform as this involves folding inverted bedding into an anticline shape, but with beds facing towards the core of the fold). The intersection on line 18+00E indicates an antiform to the SE (as does an S_0/S_2 intersection on the same line at 1+00N - the orientation of the fold axis E-W is probably due to the approximation involved in using a S_0/S_2 intersection). In conjunction with those localities where S_0 and S_2 strikes are at an angle between 65° and 90° (indicating proximity to the crest of a fold), positions of F_2 folds have been interpreted. Evidence is best for the synform and less so for the antiform and the fold at the west end of the baseline. The stresses involved during F_2 would have acted in a direction perpendicular to the fold axes; this direction is approximately parallel to the strike of S_0 , hence making it mechanically difficult to fold S_0 (as stresses would be acting along the weakest (?) direction of the sediments). However, strain would still accumulate in the rocks, and it is suggested that this was released by fracturing (together with displacement) approximately along the F_2 B ades - i.e. the NE trending faults within the grid area have been interpreted in this way.

In area C, a re-orientation of minor fold axes (F_2) and L_2 is apparent close to the fault separating the sediments and volcanics. In area B both a parasitic fold and L_2 indicate an F_2 antiform to the north.

(iv) Faulting:

The most important fault in the area appears to be the strike slip fault separating the volcanics from the sediments. The wrench movement along this fault has been inferred from the re-orientation of certain D2 elements. However, this fault is offset by those

- 9 -

inferred to be parallel to F_2 folds. It is suggested that both fault directions are D_2 in origin; the strike slip fault appearing early and releasing accumulated strain by slippage between two dissimilar blocks (i.e. sediments and volcanics). If for some reason this strain release mechanism stopped, then strain would begin to accumulate and be released by the fracturing postulated above (iii). It is assumed that re-orientation of L_2 and minor fold axes close to the strike fault is the result of these elements forming at the same time as the fault was active. The apparent displacement of the diabase/ gabbro dyke, 6a, along the strike fault, is apparently due to deflection rather than displacement (Ontario Dept. of Mines report, based upon geophysical work).

(v) Summary of structural elements:

 S_{U} : - bedding. Strike approximately S70°E, dip 50 - 80°S. D_{1} : - F_{1} folds; overturned, plunging to SW(?) at approximately 45°.

- S₁; very poorly developed, strike approximately parallel to S₀, but dip up to 14° shallower in the same direction.
- $D_2 : -F_2$ folds; closely spaced, represented by fractures paralleling the fold axes. Plunge approximately 60°SW.
 - S₂; spasmodically developed, but present in all rock types (bar 6a). Very intense in places. Strike approximately N45 - 70°E, dip either NW or SE.

Faults ; strike slip and cross faults.

; either with or without quartz carbonate veining. "Shear zones" Most pits and trenches are upon such zones.

Though not proven, it is suggested that most of the jointing of the area also belongs to D_2 . The following evidence suggests that

- 10 -

D₂ was either a weak deformation event or was developed at a high level in the crust; -

- 1) S2 only spasmodically developed, in most areas being absent.
- 2) all rocks are jointed, intensity dependent (?) upon lithology, but indicating brittle deformation.
- 3) negligible re-orientation of S_{Ω} .
- 6) Economic Geology:

In previous years exploration in the area has been for gold. The current program was undertaken to test the possibility of there being a porphyry-molybdenite deposit associated with the altered feldspar porphyry plug. As stated in the first Weekly Report, mapping was carried out with a working hypothesis in mind. It appears that the most interesting feature of the feldspar porphyry, namely its alteration zones, has been caused by a structural (D_2) rather than a hydrothermal event. As it also contains an S, cleavage and is intruded by a lamprophyre dyke, a considerable time separation appears evident between the feldspar porphyry emplacement and the mineralisation episode, D2. Thus, comparison with a porphyry deposit, such as the Brenda Mine, does not appear valid. At the Brenda Mine a sequence of events commencing with the intrusion of a quartz diorite and terminating with faulting, quartz veining and mineralisation, is presumed to have been rapid, with negligible age separation between the succeeding stages. Absent to are the high angle parallel joint sets (mineralised or not) characteristic of the porphyry deposits of Arizona; as stressed earlier, the joint sets here are complimentary. However, disseminated pyrite and haematite is present in the feldspar

- 11 -

porphyry. In addition one flake of molybdenite was found; such sparsity would not appear to indicate economic mineralisation synchronous with emplacement of the feldspar porphyry. It therefore appears that no economic mineralisation (porphyry type) occurred either as part of the feldspar porphyry during emplacement or in joint sets or fractures soon afterwards.

Based upon the evidence of biogeochemical and geophysical surveys, test pits were blasted in a zone two hundred feet north and south of the baseline from line 0+00 to 4+00E. A total of eighteen pits were blasted, and of these, one had appreciable mineralisation and two others a lesser amount. The remainder were either totally barren on with negligible mineralisation (less than six surfaces mineralised). Pit P12 was well mineralised. This was located on the diorite/sediment contact, immediately adjacent to a foliated zone. It contained an abundant quartz/carbonate stockwork, mostly as thin veins and seams. Some sericitic alteration of the sediments was noted. Pyrite is very abundant both in the stockwork, on microjoints and as seams. Of the total broken rock, eight percent carried molybdenite mineralisation, predominantly as scattered flakes and patches along the margins of the quartz carbonate veins. In one case, a vein contained ninety percent molybdenite, but the normal range is five to twenty percent. Molybdenite also occurs on microjoints with up to fifteen percent coverage. Chalcopyrite mineralisation is very minor. Pit P14, in a similar position, but removed from a foliated zone, carried molybdenite mineralisation on microjoints with coverage of ten to fifty percent on approximately two percent of the total broken rock. Pit P15 was totally barren, but molybdenite mineralisation was previously reported on microjoints from

- 12 -

the old trench just to the north of it. The three pits straddling the base line at line 0+00 were nearly barren (grab sample assay still awaited). Of the other pits, only P10 contained any appreciable mineralisation. Here, five percent of the broken rock contained molybdenite, chalcopyrite and pyrite on microjoints. In two cases, molybdenite coverage was one hundred percent, but normally five to thirty. Small quartz/calcite veins up to half an inch wide are fairly numerous.

The only other pits blasted, on lines 14+00E and 16+00E at 7+00S and 9+00S respectively, have already been reported upon in a previous Weekly Report. Assays are still awaited upon samples from pit P16 (line 14+00E). Apart from visible gold found in a pit on line 2+00E, 1+00N (see previous Weekly Report), only very minor mineralisation was found. The pits mentioned above are the best examples seen. Mineralisation in areas A, B and C has already been commented upon. The map of these areas shows what minerals were found, approximate percentages being: -

Area A: - Pyrrhotite: ten to fifteen percent coverage on less than twenty surfaces

Chalcopyrite: trace

Area B: - Pyrrhotite: up to fifteen percent coverage on a few microjoints

Chalcopyrite: trace

Area C: - Best mineralised area in pit one hundred feet west of Post #2 - claim 339806.

Sphalerite: sixty percent coverage on one surface. Five to fifteen on others.

Molybdenite: ninety percent coverage on less than ten surfaces.

Pyrite and Chalcopyrite: trace

All other mineralisation noted on map is very minor.

- 13 -

Conclusions:

Based upon the following evidence, it is concluded that a porphyry deposit does not exist within this area.

14 -

- 1) Mineralisation, as found from pits P12 to P15 and others in the vicinity, is related to quartz carbonate veined foliated zones (F_2) .
- 2) The feldspar porphyry plug was emplaced prior to F_1 and hence separated from the F_2 event by F_1 and intrusion of the lamprophyre dyke.

It is suggested that mineralisation is related to a structural event F_2 . The source of fluids involved is not known, but might possibly be related to the gabbro/diabase dykes.

During a conversation with a person who worked at the Stewart-Abate property, and from the Ontario Dept. of Mines report, it appears that the ore zone within the quartz vein has a rake of approximately fifty degrees southwest (the ore zone being sixty-five feet below the shaft collar, but at the surface just to the northeast). This corresponds very well with the orientation and plunge of F_2 . As these fracture (fault) zones are known to be mineralised (Au,Mo,Cu), the most promising area appears to be that to the southwest of the Stewart-Abate shaft. This could initially be tested by biogeochemical sampling.

BEATTY CLAIMS

Enclosed please find description of location of samples from initial trenching on the Beatty Block which have been sent to Bondar-Clegg for analyses; -

BR - 1 - Diorite - fresh, massive, well jointed. Very sparse mineralization (quartz, chalcopyrite, molybdenite), on joint surfaces. Molybdenite coverage less than 5%, chalcopyrite more abundant. Both mainly associated with quartz. 0+00 Base Line, 15' East.

BR - 2 - Greywacke - grey, fine to medium grained, massive. Molybdenite coverage on joint surfaces variable from 5 - 100%. Traces of chalcopyrite. Usually associated with quartz. Line 14+00 East, 7+005.

BR - 3 - Greywacke - as BR - 2. Sample from same trench, but of irregular stockworth of quartz veins, of variable thicknesses, carrying varying amounts of fine granular or flaky molybdenite. Chalcopyrite as small scattered patches. Line 14+00 East, 7+008.

Samples described by J. H. Morris.

F. J. Evelegh

cc: file BEATTY TOWNSHIP - Suite of Rocks

Sample BE - #1 - (U-198) Location 19+40E, 4+00N Medium grained, carbonated and oxidized felspar porphyry. Felspars zoned markedly, also kaolinized, and reach 1/8" in size. Rusty oxidation due to weathering of pyrite and specular hematite. MoS present disseminated and also in thin "layers" of seams. N. B. Specular hematite very fine grained and seen in polished section under microscope. In this sample not much present. Sample BE - #2 - (#3) Location 18+10E, 4+35N Medium grained, oxidized felspar porphyry. Kaolinisation of felspars where weathered. Disseminated MoS₂ and pyrite (+ specular hematite). Small quartz veins cut specimen - these contain MoSo also. Slips in sample also mineralized with pyrite. Sample BE - #3 - (17/5), Location 1+30E, 3+40N Grey quartzite, (greywacke) with disseminated pyrite and also pyrite in seams plus small quartz veins. Quartz veins contain pyrite and MoSo. Sample BE - #4 - (17/5/5) Location 14+50E, 2+30N Felspar porphyry with crystals up to 1/4". Disseminated chalcopyrite present plus some pyrite. Also fine specks of MoSo and specular hematite (actually mineral may not be specular hematite since dull grey not as blue as MoS₂ but has red streak). Sample BE - #5 - (Y-9363) Location 9+30E, 11+00N Felspar porphyry with pyrite on seams. Spec probably mixture with quartzite. Sample BE - #6 - (U-499) Location 11+20E, 3+80S Grey (green) quartzite with some pyrite seams. Fine grained MoSo associated with clear to white quartz all through sample. May be injections along bedding planes. Also Mas, on hair line fractures. Sample BE - #7 - (Y-9366) Location - small pit 1+00W, 1+20N Pale green quartzite with quartz veins. MoS2 restricted to veins especially concentrated at contacts. Few hair line fractures have MoS2, pyrite. Sample BE - #8 - (Y-9364) Location 2+00W, 8+50N Grey quartzite plus disseminated pyrite and some chalcopyrite. Chalcopyrite may be on hair line fractures. Small quartz vein has pyrite, chalcopyrite within.

Sample BE - #9 - Location - Dump material near shaft of Stewart Abate. Seams MoS₂. Note small rusty weathered carbonate vein. Some chalcopyrite present and also disseminated MoS₂. Rock type appears to be quartz vein material.

a da Bacela e para se

BEATY TOWNSHIP - Suite of Rocks - Page 2.

10 12

Sample BE - #10 - (Y-9361) Location 14+50E; 3+40N Mixture of felspar porphyry and quartzite - almost barren but does contain very fine specks of pyrite and possibly chalcopyrite.

Sample BE - #11 - (#6) Location 15+50E, 11+00S From trench blasted on quartz vein material. Scattered chalcopyrite in vuggy material - oxidation due to alteration after blasting. Carbonate present and also secondary copper minerals. Note grey mineral associated with chalcopyrite.

Sample BE - #12 - (#4) Location 14+80E, 2+00S. Felspar porphyry with pyrite and chalcopyrite on slips. Some fine MoS₂ in rock.

Sample BE - #13 - (U-487) Location - small pit - 12+30E, 2+60S Brecciated vein material with galena and sphalerite, minor chalcopyrite and pyrite. Vein material is quartz and carbonate.

Sample BE - #14 - (Y-9362) Location 10+00E, 4+60N Grey quartzite with carbonate on slips. Note many fine, weathered fractures and alteration around them.

BEATTY ROCK SAMPLES (BR Series)

(R. E. M. CONDUCTING ZONES)

Bample No.	Location	Description
BR - 1	Line 12+00E; 5+008	Light grey fine grained quartzite with disseminated pyrite. Narrow seams of pyrite, chalcopyrite with minor MoS ₂ .
BR - 2	Line 14400E; 7+008	a) Light grey quartzite with many small seams of MoS ₂ , also a few seams of pyrite. Minor fractures with quartz/ carbonate material and possibly two gold specks. Moly seams from 1/4" to 3/4" apart. Some chalcopyrite is also present.
BR - 3	same location ,	b) 1" quartz-carbonate chalcopyrite vein in grey quartzite. MoS, on seams and disseminated in quartz veins. Check for Au.
BR - 4	Line 16+00E; 0+50N	Light greenish-grey felspathic quartzite intermixed with felspar porphyry. Disseminated pyrite present.
BR - 5	Line 16+50E; 9+00S	Altered diorite with disseminated pyrite. Chalcopyrite and pyrite with narrow quartz veins. Much disseminated MoS ₂ associated with quartz/carbonate vein. Bright apple green patches occur within the diorite, close to the quartz carbonate veins. The mineral appears to be a carbonate.
BR - 6	Line 18+00E; 6+508	Quartz vein material at contact of diorite and quartzite. Contains MoS ₂ and chalcopyrite with pyrite. Small rusty carbonate stringers in quartz material.
BR - 7	Line 18+00E; 9+108	Light grey quartzite with quartz/ carbonate vein material (as stringers) with disseminated pyrite present and MoSo on one seam.

DESCRIPTION OF P. H. M. C. SAMPLES BEATTY BLOCK, BEATTY TOWNSHIP

Checking R. E. M. conducting zones.

.

.

Number	Description
01025	Mainly white to greyish fine sand. Good concentration of heavy minerals under hand lens with magnetite plus speck of galena seen. Minor amount of organic material (less than 1/2%).
0-1026	Light brown to grey clayey sand. Some grit pieces up to 1/2". Heavy mineral content obscured due to clay material.
0-1027	Blue-grey clay with some black muck. Sample contains minor organic material.
C-1028	Blue-grey clay with about 5% black muck. Some sand grains in the black muck.
0-1029	Mainly black muck but some gravel-sized pieces up to 1" and a sandy texture. Contains about 10,0 organic material.
0–1030	Dark brown to black clayey sand with some gravel pieces up to 3/4". Sand fraction contains abundant black mineral grains.
0-1031	Mainly clayey gravel. The clay is dark brown to black with angular gravelly pieces up to 3/4" in size. Some organic material present.
0-1032	Dark greyish-brown slightly clayey sandy topsoil. Contains angular fragments up to 1/2".
C-1033	Orange brown medium grained sand with about 10% black muck. Some heavy minerals seen with hand lens (magnetite).
0–1034	Dark orangy brown sand. Slightly more coarse grained than C-1033 but still contains about 10% organic black muck.
0-1035	Dark brown slightly greyish topsoil plus angular limestone fragments. About 5% organic content.
C-1036	Medium brown slightly reddish silty topsoil with rust-red angular fragments up to 1/2" size. About 5% organic material.
C-1037	Light to medium brown silty clay with angular fragments of weathered feldspar porphyry.
0-1038	Slightly silty clay topsoil with weathered angular fragments of feldspar porphyry.

P. A. R. Brown September 11, 1972.
