#### SUMMARY.

During the winter of 1982 a UTEM survey was carried out on Cominco's Dun property, near Iroquois Falls Ontario. The target was a deep massive sulphide body of the Kidd Creek type, below the thick overburden cover. The survey was performed by Cominco Ltd. personnel using the newly developed UTEM III system, a state-of-the-art time domain EM system which has the capability of great depth penetration.

The survey outlined several poor conductors which appear to be conductive overburden responses, though a long bedrock conductor was also detected. This bedrock anomaly was quite shallow (50 metres) and had been previously detected by a vertical loop survey and subsequently drill tested. Graphite was determined to be the source of the anomaly. No other bedrock conductors were detected.

Since the target of the survey was a highly conductive body at depth, below the limits of conventional geophysical methods, the survey was based on a line spacing of 300 metres. If such a body existed in the survey area, the lateral coverage of the system would have identified it at such a line spacing, though more detailed line spacing would be required over the anomaly to determine its full potential.

Therefore, the UTEM survey indicates that no significant massive sulphide body exists to a depth of 400-500 metres within the survey area.

## INTRODUCTION

Cominco Ltd. acquired property in the established Timmins mining camp early in 1982. The objective was to utilize the newly developed UTEM 111 system to test for a Kidd Creek type orebody, along a possible projected extension of the favourable geology beneath a thick overburden cover. Previous geophysical systems employed in the area did not have the depth penetration or the interpretability of the UTEM system, and thus would have missed such a body at large depths.

During the period February 9 to March 2, 1982, Cominco Ltd. personnel carried out a UTEM survey over the Dun claims. Those involved in the survey were K.N. Hendry (geophysicist), R.W. Holroyd (geophysicist), E.T. Eadle (geophysicist) and D.D. Laronde (technician). A total of 32.4 km of lines were surveyed from 9 transmitter loops, and a 10th small loop was used to further define an anomaly.

### EQUIPMENT AND PROCEDURES

The UTEM III system developed by Lamontagne Geophysics was used on the Dun property in order to achieve maximum possible depth penetration. UTEM (University of Toronto Electro-Magnetometer) is a wideband, time-domian ground EM system which was designed to achieve the sensitivity and interpretability necessary to allow exploration in geophysically difficult area, such as at large depths, in conductive terrains, and in areas of significant cultural noise (powerlines etc.). The UTEM III system is microprocessor controlled and employs digital recording of the field data on a cassette tape.

2

The UTEM method utilizes a transmitted signal of low frequency and precise triangular waveform which is passed through a large fixed wire loop. The receiver sensor is a coil which, for this survey, measures the vertical magnetic component (Hz) of the local electromagnetic field and which responds to the time derivation of that field. The system is also capable of measuring other components, ie. the horizontal electromagnetic and electronic fields in the X and Y direction (Hx, Hy, Ex, and Ey respectively), but these components are usually used in specialized cases and are not used in standard surveying practice.

Since the transmitted current waveform is triangular, a square wave will be detected at the receiver coil in the absence of any anomalous responses. Any distortions from the perfect square waveform are due to local electrically conductive features (geological or cultural) and which constitute a UTEM anomaly. This distortion is measured at the receiver by determining the amplitude at 10 delay times which are the average over established time windows and which cover nearly the entire area between waveform transitions, le. from positive peak to negative peak. The time channels are set up in a binary fashion with the earliest and narrowest being channel 10, and the latest and widest being channel 1. Channel 10 is typically not processed due to its noisy nature and susceptibility to slight instrument drifting. The higher numbered channels (short time) correspond to high frequencies whereas the lower numbered channels (late time) corresponds to low frequencies. Therefore responses on lower numbered channels reflect an increase in the conductivity of the anomalous body, such that a highly conductive body (massive sulphides or graphite) will respond on all nine channels.

The base frequency of the system is selectable, usually about 30 or 15 Hz, 0.5 Hz from a sub-harmonic of powerline frequency, causes the powerline interference to show up as slow beating in the received signal. An experienced operator can recognize this noise and average for a longer period of time to eliminate such effects and obtain a stable reading. The receiver is capable of sticking any pre-set number of cycles in order to increase the signal to noise ratio.

Five large fixed transmitter loops were used to carry out the survey, each consisting of single strand insulated wire, energized with current from a transmitter which is powered by a 1.75 kw motor generator. For logistical reasons the loops were not all of equal size but were in the order of 1500m x 1000m. A total of 9 loops were established with lines surveyed perpendicular to the south side of the loops. A small loth loop was surveyed perpendicular to its north side in order to evaluate an anomalous response. Due to the capabilities of the UTEM system and the nature of the target the grid lines were 300 metres apare and readings were taken at 100 foot intervals.

A portable field computer which is part of the UTEM system, enables the processing, plotting and interpretation of the data to proceed during the survey. The data is digitally recorded by the receiver and is played back into the computer which remains in the base camp.

#### PRESENTATION OF DATA

The computer processing of the data produces profile plots of 9 channels for each line, though in order to properly interpret the data other specialized types of plots are required. Standard normalized plots (continuously normalized) provided for each line surveyed, and on lines with anomalous responses, point normalized and decay plots are plotted to aid in the interpretation of the anomaly. As is a typical practice in UTEM surveys, data from channels 2 to 9 are normalized to the channel 1 data. This is done since the primary field intensity attenuates rapidly with increasing distance from the transmitter loop and thus the secondary field must be normalized to that component (Hz for this survey) of the primary field. In areas where the ground response vanishes at late time, the channel 1 value is a direct measure of the primary field and is used to normalize the value of the earlier time channels. A calculated value of Hz is used to normalize channel 1, but relies on the positions of the loop and the receiver being accurately known. The normalizing scheme used is as follows:

3

1. Standard normalization (continuously normalized)

a) for channel 1:

% Chl anomaly =  $(Chl-P) \times 100\%$ 

where Ch1 - measured amplitude for channel P = primary field from the loop at that station

- b) for channels 2 to 9:
  - % Chn anomaly =  $(Chn-Chl) \times 100\%$ Chl

where Chn = measured amplitude of channel n (n = 2 to 9)

2. Point normalized plots (normalized to a particular station)

a) for channel 1:

% Chl anomaly = <u>(Chl-Pa)</u> x 100% Pa

b) for channels 2 to 9:

% Chn anomaly = <u>(Chn-Chla)</u> x 100% Chla

where Chn - measured amplitude of channel n

Chla = reduced Chl value at station 'A'

The standard (continuously normalized) plot provides a qualitative interpretation of the responses across a section line, ie. anomaly location, shape of conductor, approximate depth to top of the conductor and relative background conductivities. The point normalized plots display only the amplitude variation of the secondary field along the line, ie. only the magnetic field from the induced currents in the ground and thus provide a quantitative interpretation. Further quantitative interpretation, such as t's of the conductor, overburden and host rock, are done by means of specialized plots such as decay and time plots.

The UTEM data are plotted in profile form on three separate axes. Channel 1 data are plotted on the bottom axis, channels 2 to 5 on the middle axis, and channels 5 to 9 on the top axis. The channel 5 profiles are plotted on both the middle and top axes as a reference between early and late time channels since it is usually necessary to plot them on different vertical scales.

## DISCUSSION OF RESULTS

Several anomalies resulted from the survey, but with only one apparently related to a bedrock source. The remainder are apparently due to conductive overburden. The bedrock anomaly, detected across the southern end of lines 18E to 30E at about 1400S, has a conductivity-width of 15-20 mhos and a depth of about 50 metres. This anomaly has been previously drill tested, intersecting graphite in felsic fragmentals and thus warrants no further investigation. A possible extension of this bedrock anomaly on lines 51E and 54E at about 1650S was further tested by loop 310, placed to the south of the anomaly. This test produced no anomaly and indicated that the anomaly is not a dyke-like bedrock body, but an edge of a flat-lying feature, probably conductive overburden.

The numerous other anomalies show typical overburden responses, ie. anomalous in only the earliest channels (9,8 and 7) which can be related to high frequency and hence low conductivity, and are quite shallow (50 metres). These anomalies have conductivity widths of less than 10 mhos. Such responses can result from a thickening of conductive overburden in a bedrock trough, or an accumulation of conductive clays in the overburden.

#### CONCLUSIONS AND RECOMMENDATIONS

A conductive massive sulphide body of the Kidd Creek type does not occur on the property, since such a deposit would have a t value of greater than 50 mhos. Even with the 300 meter line spacing, this system would detect the presence of such a feature.

Mining Recorder Ministry of Natural Resources 60 Wilson Avenue Timmins, Ontario P4N 2S7

Dear Sir:

RE: Geophysical (Electromagnetic) Survey on Mining Claims P 622830 et al in the Township of Dundonald.

The Geophysical (Electromagnetic) survey assessment work credits as listed with my Notice of Intent dated August 5, 1983 have been approved as of the above date.

Please inform the recorded holder of these mining claims and so indicate on your records.

Yours very truly,

E.F. Anderson Director Land Management Branch

Whitney Block, Room 6450 Queen's Park Toronto, Ontario M7A 1W3 Phone: 416/965-1380

Mr. William L. Good Mining Recorder Ministry of Natural Resources 60 Wilson Avenue Timmins, Ontario P4N 2S7

Dear Sir:

Enclosed are two copies of a Notice of Intent with statements listing a reduced rate of assessment work credits to be allowed for a technical survey. Please forward one copy to the recorded holder of the claims and retain the other. In approximately fifteen days from the above date, a final letter of approval of these credits will be sent to you. On receipt of the approval letter, you may then change the work entries on the claim record sheets.

For further information, if required, please contact Mr. F.W. Matthews at 416/965-1380.

Yours very truly,

E.F. Anderson Director Land Management Branch

Whitney Block, Room 6450 Queen's Park Toronto, Ontario M7A 1W3 Phone: 416/965-1316

Ministry of Natural Resources Notice of Intent for Technical Reports

1983 08 05

2.5303

An examination of your survey report indicates that the requirements of The Ontario Mining Act have not been fully met to warrant maximum assessment work credits. This notice is merely a warning that you will not be allowed the number of assessment work days credits that you expected and also that in approximately 15 days from the above date, the mining recorder will be authorized to change the entries on his record sheets to agree with the enclosed statement. Please note that until such time as the recorder actually changes the entry on the record sheet, the status of the claim remains unchanged.

If you are of the opinion that these changes by the mining recorder will jeopardize your claims, you may during the next fifteen days apply to the Mining and Lands Commissioner for an extension of time. Abstracts should be sent with your application.

If the reduced rate of credits does not jeopardize the status of the claims then you need not seek relief from the Mining and Lands Commissioner and this Notice of Intent may be disregarded.

If your survey was submitted and assessed under the "Special Provision-Performance and Coverage" method and you are of the opinion that a re-appraisal under the "Man-days" method would result in the approval of a greater number of days credit per claim, you may, within the said fifteen day period, submit assessment work breakdowns listing the employees names, addresses and the dates and hours they worked. The new work breakdowns should be submitted direct to the Lands Management Branch, Toronto. The report will be re-assessed and a new statement of credits based on actual days worked will be issued.

MEMORANDUM TO:	-	JUL -7 1983
Mr. F.W. Matthews Mining Administrator, Mining Lands Section.		J. R. MORTON J. C. SMITH G. SHERMAN
SUBJECT: File 2.5303 Cominco Ltd.	R	M. SMALL

I believe this to be the first submission of an advanced ground time domain electromagnetic instrument made by an exploration company. A calculation of the cost of this survey relative to more conventional EM submissions indicates that on a dollar basis the survey is probably worth about the same price as conventional coverage at say 100m line separation. Although more information is contained in this survey the method of presentation of the data certainly could stand some improvement if it is to be of optimum value to the exploration community. Based on research experience with another similar type of instrument on our test range near Night Hawk Lake we have some sound recommendations as to how to present this data more completely.

Because of the problem outlined above we hope to set forth recommendations on formats acceptable for assessment work credits in the near future.

For the present it seems reasonable to accept this data, as is, based on the fact that it has the potential of revealing much more soundly, the geological and physical characteristics of the target as outlined from surveys using PEM UTEM and EM-37 instrumentation.

MINING LANDS SECTION

# memorandum

Date: July 5, 1983

Mr. R. Barlow Ontario Geological Survey 77 Grenville Street Toronto, Ontario

To:

We usually require the actual readings at each station for a geophysical survey. However, the enclosed UTEM survey has been submitted with no readings and a line spacing of 300 meters. Please clarify if readings are required and comment if you consider the line spacing to be excessive for this kind of survey.

Mining Recorder Ministry of Natural Resources 60 Wilson Avenue Timmins, Ontario P4N 2S7

Dear Sir:

We have received reports and maps for a Geophysical (Electromagnetic) Survey submitted under Special Provision (credit for Performance and Coverage) on Mining Claims P 622830 et al in the Township of Dundonald;

This material will be examined and assessed and a statement of assessment work credits will be issued.
