1.0 Introduction

Bradley Bros. Limited was contracted by Hucamp Mines Ltd. to diamond drill 14 holes on the Dundonald property located in Dundonald and Clergue Townships, Porcupine Mining Division, District of Cochrane. The Dundonald property is approximately 45 kilometres northeast of the City of Timmins and 15 kilometres southwest of the Town of Iroquois Falls. The property consists of a combination of surface and mineral rights that are currently under option to Hucamp Mines Limited from Falconbridge Limited.

A total of 2043 metres of NQ diamond drilling was completed in 14 diamond drill holes between April 9 and May 16, 2001. The core was logged by Hucamp personnel at the MPH office in Porcupine, Ontario and has been transported and stored on the Alexo property approximately 4 kilometres from the Dundonald property.

Nickel, Cu, Co, Pt, Pd, and Au analyses were completed on all sulphide intersections within the komatiitic rocks and Pt, Pd and Au (with a few selected samples analyzed for Cu) analyses on samples within the Dundonald Sill.

2.0 Location and Access

The Dundonald property is approximately 45 kilometres northeast of the City of Timmins and 15 kilometres southwest of the Town of Iroquois Falls. The property is located within 2 kilometres of Highway 67, a paved roadway that connects Highways 101 and 11. A gravel road extends south from the highway onto the northern and western portions of the property. Another gravel road further to the east accesses the eastern and southern portion of the property. Electrical lines are located less than 2 kilometres north of the property boundary running parallel to Highway 67. In addition, the Ontario Northland Railway, servicing the Kidd Creek Metsite, is 2 kilometres north of the property and joins the main line approximately 5 kilometres to the east at Porquois Junction.

3.0 Topography, Vegetation, and Water Availability

The area is well drained with low to moderate topographic relief. Large outcrop ridges of intermediate volcanics and gabbros dominate the centre of the property and are surrounded by sand plains and muskeg swamp. Outcrops represent approximately 5% of the property. Vegetation varies from mixed deciduous forests to black spruce and alder swamps. Trees include jack pine, aspen, birch, and scrub maple on the well drained outcrops and sand plains to muskeg swamp with black spruce, cedars, and alders. The availability of water on the property is good due to the presence of several beaver ponds and pits within the property boundaries.

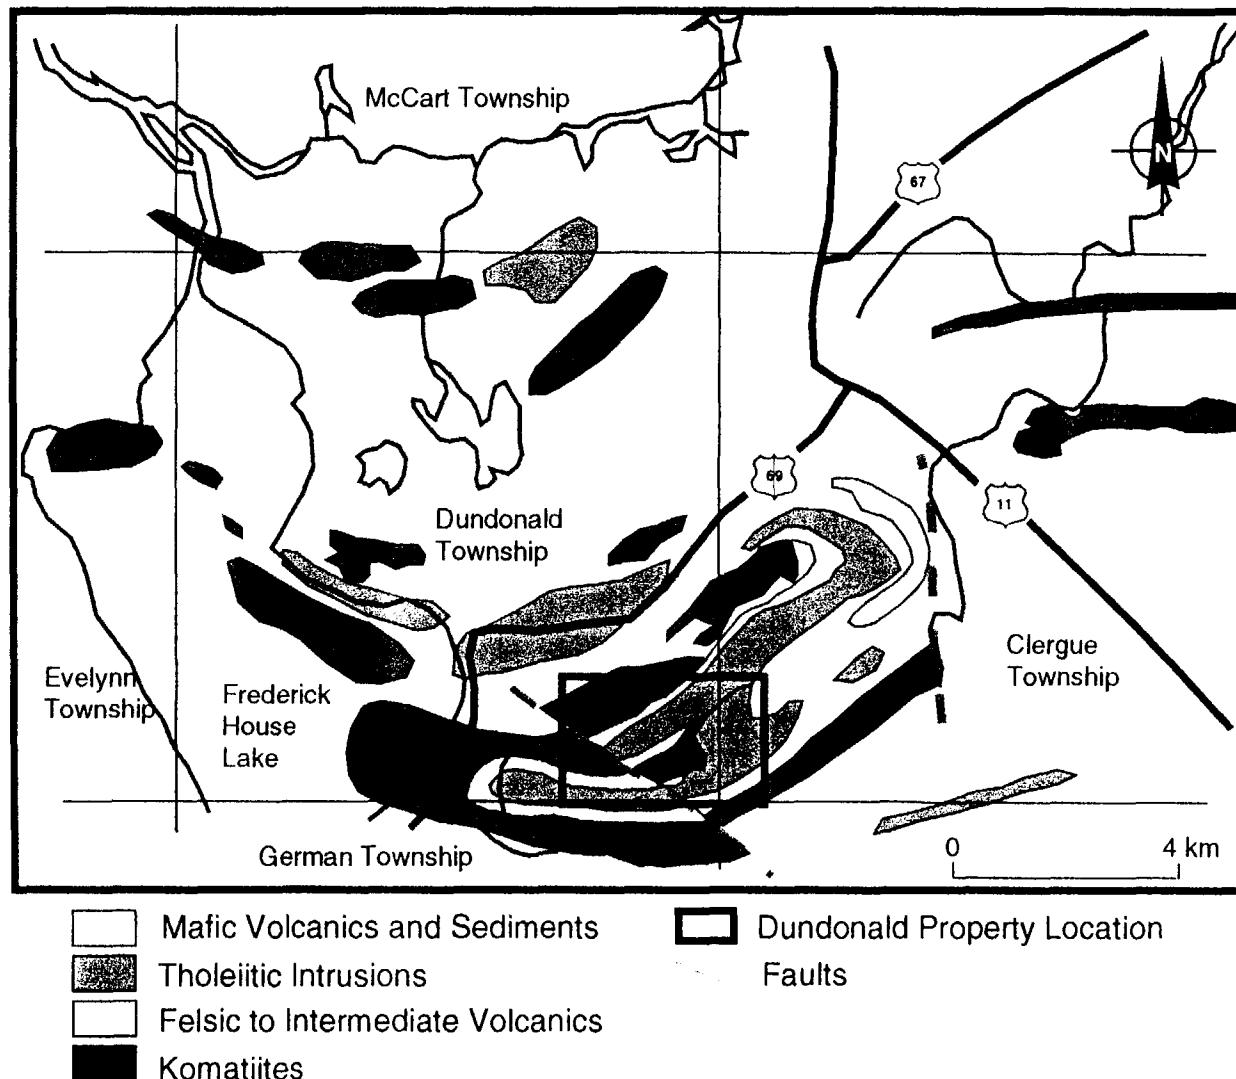

Figure 1: Geological map of Dundonald Township area showing major lithological units and property location (adapted from Jackson and Fyon, 1991).

FALCONBRIDGE LIMITED: DUNDONALD PROPERTY MAP

4.0 Property

The property consists of 3 patented, 38 leased and 15 unpatented contiguous mining claims representing 951 hectares in Dundonald and Clergue Townships. The patents, leases and unpatented mining claims have been compiled by Falconbridge over the last 40 years. A list of the patents, leases and claims is appended to the back of this report.

5.0 Regional Geology

The rocks contained within Dundonald and Clergue Township have been interpreted to be part of the Kidd-Munro assemblage. Jackson and Fyon (1991) describe the Kidd-Munro assemblage as an east-southeast striking zone that extends from Kidd Township in the west to the Grenville Front in Quebec. The Kidd-Munro assemblage ranges in age from 2717 Ma to 2711 Ma (Corfu, 1993).

The Kidd-Munro assemblage comprises a wide range of volcanic rocks including: komatiitic dunites, peridotites, pyroxenites, and basalts; magnesium and iron-rich tholeiitic basalts; tholeiitic picrites; high-aluminum basalts; high phosphorous andesites; and high silica rhyolites. Sedimentary rocks tend to be restricted to thin interflow graphitic argillites with varying amounts of cherty material and sulphides. A wide range of intrusive rocks occur within the Kidd-Munro assemblage and include: differentiated tholeiitic and komatiitic sills; intermediate to felsic plutons, and abundant late diabase dykes.

Lower greenschist facies metamorphism dominates the Kidd-Munro assemblage with isolated windows of prehnite-pumpellyite facies metamorphism and amphibolite facies contact metamorphism around the intrusions. Chlorite is the most common mineral associated with metamorphism with lesser amounts of muscovite, hematite, albite, and quartz. Ultramafic rocks are dominated by serpentine alteration, which is typically pervasive and is accompanied by many other alteration minerals including magnetite, calcite, tremolite, and chlorite.

6.0 Property Geology

The Dundonald property is located in the central-western portion of the Kidd-Munro assemblage. The stratigraphic succession on the Dundonald property is fairly complex consisting of a late differentiated tholeiitic intrusion which intrudes a sequence of komatiitic volcanic rocks separated by calc-alkaline volcanic rocks. There appears to be at least 4 separate komatiitic sequences within the property boundaries. The volcanic rocks have been folded about a northeast trending fold axis. The volcanics strike roughly northeast-southwest and dips steeply to the north or south depending on the position within the fold. Topping directions also support the presence of a large fold with tops to both the north and south depending on the location in relation to the fold.

The calc-alkaline volcanic rocks range in composition from rhyolites to basalts. The volcanic rocks are a combination of complex flows that range in texture from pillow, fragmental, hyaloclastic, and massive flows. The flows vary laterally from massive to fragmental and changes over a relatively short strike length. Individual flows can be traced for 10's to 100's of metres. The calc-alkaline volcanic rocks contain varying proportions of pyrite and pyrrhotite representing up to 40% of the unit. Minor amounts of interflow graphitic argillitic sediments can be traced for several 10's of metres along strike and contain upwards of 20% pyrite and pyrrhotite, occasionally with trace chalcopyrite.

The komatiitic rocks range in composition from komatiitic basalts to dunites. The komatiitic sequences contain multiple flows within each sequence. Flow units can range from several hundreds of metres to less than 2 metres in thickness. The komatiitic rocks are composed of rubbly flow tops, spinifex-textured zones, olivine orthocumulate, mesocumulate, and adcumulate. Not all of the flows contain all of the textures described. Thin interflow, graphitic argillites occur between the thinner komatiitic spinifex-textured flows. Flows with a basaltic or pyroxenitic composition tend to alter to chlorite-tremolite rocks and flows with a dominantly olivine composition alter to mainly serpentine and magnetite. Large accumulations of olivine mesocumulate to adcumulate within the komatiitic sequences tend to indicate the presence of possible thermal erosion channels.

The thick differentiated tholeiitic intrusion varies in composition (base to top) from a peridotitic to dunitic olivine mesocumulate to adcumulate grading to a pyroxenitic cumulate which contains primarily diopside with phenocrysts of olivine that grades into a thick sequence of fine grained to coarse grained gabbros.

7.0 Diamond Drilling

Fourteen diamond drill holes representing a total of 2043 metres were drilled on the Dundonald property from April 2001 to May 2001 (table 1). Diamond drilling consists of mainly NQ drill core with some BQ drill core where necessary to get through bad ground conditions. Please refer to Appendix 1 for a summary of drill logs and header pages.

8.0 Assay Analysis

A total of 320 samples have been sent for assay analysis for Ni, Cu, Co, Pt, Pd, and Au or Pt, Pd and Au. Cumulate pyroxenites within the Dundonald Sill were sampled for Pt, Pd and Au, even where no visible sulphides were observed. Please refer to the appendix for a complete listing of the assay results.

Table 1: Diamond Drill Hole Summary.

9.0 Results and Conclusions

The diamond drill hole program completed on the Dundonald property was successful in reaching or exceeding the preliminary expectations of the program. Only a few of the holes encountered bad ground conditions that slowed progress and resulted in the abandoning of a single drill hole (HUF-9A-01).

Eleven drill holes focused on 3 areas were completed to test for the presence of Ni-Cu-PGE mineralization associated with the komatiitic stratigraphy in the area. HUF-01-01 and HUF-02-02 were drilled to test the western extension of known Ni mineralization along strike. The holes were successful in identifying low grade Ni mineralization within the komatiite stratigraphy. Four holes (HUF-03-01 to HUF-06-01) tested the western extension of the Dundonald South zone and intersected a similar volcanic stratigraphy but failed to intersect any anomalous mineralization. Five holes (HUF-07-01 to HUF-10-01) tested the known mineralization associated with the Dundonald South deposit. These holes successfully intersected the mineralized sequences and returned some of the best grades associated with the deposit. The continuous komatiite stratigraphy and the distribution of known Ni-Cu-PGE zones within the area indicates there is a great potential to expand the existing resources and discover new Ni-Cu-PGE zones.

A fence of 3 holes (HUF-11-01 to HUF-13-01) was drilled through the Dundonald Sill along strike, north of the Mighty Pt-Pd zone. The holes successfully cross cut the intrusive stratigraphy and identified the reef style Pt-Pd mineralization. This indicates that the Pt-Pd mineralization is a regional mineralized

zone that can be expected to continue throughout the strike length of the Dundonald Sill and has been identified over 5 kilometres of strike.

10.0 Recommendations

Additional diamond drilling is recommended for the Dundonald property. The diamond drill program should be divided into two separate programs based on the anticipated results. The first program should be a definition drill program to expand on the currently identified Ni-Cu-PGE resources within the property boundaries. This program is drill intensive and would require a substantial capital expenditure to complete properly. The second program is a more property scale drill program designed to test the komatiite stratigraphy throughout the property. Targets would be selected based on the existing geophysical coverage and previous diamond drilling. Down hole pulse-EM is highly recommended for all diamond drill holes completed on the property.

0 7		Overburden						
7 20		Pyroxenite Massive Flow KPx	Light green, VFG, nonmagnetic, soft, massive pyroxenitic flows. The pyroxene consists of a VFG Flow feltlike mass (dike cumulate) to VFG mesocumulate. It is composed of 70-75% green pyroxene laths, 10% black VFG chlorite specks, and 5-7% white plagioclase. MINERALIZATION: 0.5% to trace VFG disseminated pyrrhotite throughout. STRUCTURE: moderate to well fractured with poor RQD's. 17-19.3 MINERALIZATION: 1% VFG-Fg disseminated pyrrhotite. 17.85-18.05 25%, white quartz-carbonate, ragged pattures (fracture filling) pseudo breccia. Lower contact appears to be a flow contact with variolitic margins.					
20 34.3		Pyroxenite Flow Brecchia KPx, bx	Light green, VFG, nonmagnetic soft, pyroxenitic breccia. The unit consists of 80-90% light green angular small (1-5 cm size) pyroxenite fragments held together by either VFG blackish green scoria-like material.

			39-40 MINERALIZATION: 5% Vfg diss pyrite.						
42.9	54.75	Peridotite Flow KPx	Black, Fg, massive, magnetic, peridotite flow. It is composed of 85-90% black fine (1mm) olivine cumulate grains in mutual contact surrounded by light green Vfg aphanitic pyroxenite groundmass. The peridotite is cut by 3-5% very fine black serpentine-chlorite fractures producing a mesh-like texture. MINERALIZATION: Nil sulphides.						
54.75	70.9	Pyroxenite Flow KPx	Greenish grey, Vfg, soft, non-magnetic, Pyroxenite flows. They consist of 10% light green Fg-my pyroxene laths in a Vfg aphanitic pyroxenite groundmass (54.75 - 60.4 & 65 - 70.5). The flows are cut by 5-8 dark green Vfg serpentine filled tensional fractures and gashes. Rare black serpentine spheres scattered throughout. 60.4-64.4 Light green, Olivine spinifer pyroxenite Flow. The flow consists of 50% black olivine laths (my to eg) randomly oriented in a Vfg aphanitic pyroxenite groundmass.

Dear Sir or Madam

Submission Number: 2.23408
Transaction Number(s): W0260.00689

Subject: Approval of Assessment Work

We have approved your Assessment Work Submission with the above noted Transaction Number(s). The attached Work Report Summary indicates the results of the approval.

At the discretion of the Ministry, the assessment work performed on the mining lands noted in this work report may be subject to inspection and/or investigation at any time.

If you have any question regarding this correspondence, please contact STEVEN BENETEAU by email at steve.beneteau@ndm.gov.on.ca or by phone at (705) 670-5855.

Yours Sincerely,

A handwritten signature in black ink, appearing to read "Ron Gashinski".
