PROGRESS REPORT-1982 PROGRAM
BELL CREEK PROJECT
MURPHY-HOYLE TWPS.
TIMMINS AREA
ONTARIO

SUMMARY

Exploration work in Murphy and Hoyle Townships by Amax, its predecessor Rosario Resources Inc., in partnership with DuPont Minerals Exploration Ltd. over the past 4 years has identified several auriferous environments, and located a number of gold deposits within them. Three distinct occurrences, namely the Marlhill, Bell Creek and North zones, have been explored in some detail. The Marlhill zone, about 300 feet west of a known showing, was evaluated by surface sampling and drilling. It is a quartz vein occurrence having fair grade, but exhibiting the erratic nature of quartz vein deposits. The occurrence requires more work both on strike and at depth.

The Bell Creek Zone was found in 1980, in the course of drilling electrical conductors, then traced along strike by drilling in 1981, and proved to consist of a number of horizons with concentrations at the east and west ends. The east zone was tested for continuity in 1982. Although more drilling is necessary to define Bell Creek - East Zone, it appears to have a potential of about 300,000 tonnes in the 4 gram per ton range to the depth drilled. The Bell Creek - West Zone is erratic and structurally complex and will require further definition at a later date.

The North Zone on which most work has been done, was discovered late in 1981 by a routine test of an induced polarization anomaly. Follow-up drilling early in 1982 confirmed the existence of mineralization and a total of 41 holes were drilled during the year on the zone and its extensions. The mineralized horizon has been traced for 820 metres in a west-northwest direction. Within a portion of the horizon extending 380 metres westward from Bell Creek, and to a depth of 220 metres, a gold deposit has been outlined having geological reserves of 426,000 tonnes grading 8.13 grams ton/Au. (Uncut and undiluted) Average width of the deposit is 3.87 metres.

The gold deposit is open to the east and west and at depth, however, to the east it is expected to terminate against a regional graphite unit within about 60 metres of the most easterly drill section. At the western end, the deposit narrows to about one metre and the grade decreases. Similarly the deeper holes suggest a decrease in the width of the zone, but the grades in these holes are about the average of the deposit or better.

In view of the encouraging results, a pre-feasibility study is being undertaken on the North Zone deposit, and a comprehensive geophysical program is planned on the adjacent properties followed by drilling of any targets generated, and continued drilling on the Bell Creek and Marlhill Zones. Further work on the North Zone in 1983 will depend on the recommendations of the pre-feasibility study.

CONCLUSIONS

Diamond drilling on the North Zone at Bell Creek has outlined a small gold deposit that merits further investigation by drilling, and possibly an underground examination. The deposit represents a concentration of gold on a stratigraphically controlled mineralized horizon consisting of quartz and sulphide mineralization in an envelope of carbonate alteration. The mineralized horizon has been traced for about 820 metres, and the North Zone deposit occupies some 380 metres westward from Bell Creek. Using a cut-off of 3 grams over 2 metres a geological reserve of 426,000 tonne grading 8.13 grams Au/ton (uncut and undiluted) has been outlined to a depth of 220 metres. Average width of the deposit is 3.87 metres.

Although some gaps exist between the 37 holes drilled into the deposit, the consistency and regularity of the mineralization indicate that underground exploration is a logical next step after limited additional drilling. At a vertical depth of 220 metres the deposit is similar mineralogically to the upper parts but, at 1.05 metres, is considerably narrower. From the drilling to date the deposit does not appear to have a plunge within the mineralized horizon but additional drilling, particularly at depth, might change the assumed configuration of the occurrence.

The Bell Creek zone differs little from the North Zone mineralogically, but has a lower overall grade. Very preliminary estimates put geological reserves at 300,000 tonnes grading 4 grams Au/ton, but more drilling is necessary to define the zone and determine the grade.

Two holes drilled on the Marlhill Zone confirmed the curvilinear nature of the vein, and one hole intersected fair gold values. More drilling is warranted to test the continuity of the vein.

Experience has shown that it is possible to detect potential gold bearing mineralization in the Bell Creek area by geophysical means. Selected areas on the extension of known mineralization, and on newly acquired ground, should be surveyed to outline possible targets.

RECOMMENDATIONS

A multiphase program has been recommended for the Bell Creek Project in 1983. The first phase, costing \$650,000 and commencing in January, will evaluate the outlying claims and further define the Bell Creek and Marlhill Zones. The program, consisting of geophysical surveys and diamond drilling will be completed by April 1983.

Later phases of the program will depend on recommendations of a pre-feasibility study currently underway. Further work will likely involve additional drilling in the North Zone including a pilot hole for a shaft. Environmental studies, work permit applications, route selection, road and powerline construction and collaring of a shaft could be undertaken in 1983, if underground development is found to be feasible. The cost of such a program could amount to 1.4 million dollars over and above the first phase expenditure.

INTRODUCTION

Exploration work over the past 4 years by Amax Minerals Exploration (and its predecessor Rosario Resources Inc.) in partnership with DuPont Canada Exploration Ltd., has identified several auriferous environments in Murphy and Hoyle Townships and located a number of gold deposits within them in the Hoyle Twp. sector. Drilling in one of the deposits, designated the North Zone, has outlined sufficient reserves to consider underground exploration. Several other mineralized zones merit tracing by geophysical methods and testing by drilling, and another deposit, the Bell Creek zone, requires further definition drilling. Depending of the outcome of a pre-feasibility engineering study, a program leading to commencement of underground investigation of the North Zone is recommended.

The 1982 program covered in this report was designated under the Ontario Mineral Exploration Program making all expenditures on preliminary explorations eligible for a 25% grant from the Province. The proposed 1983 program has been similarly designated but will include some advanced exploration, which is entitled to a 6.25% grant.

PROPERTY

The Bell Creek project comprises ~~348~~ parcels (40 acre claim equivalents) in the form of patented lots, staked and optioned claims in Hoyle, Murphy and Whitney Twps. The parcels lie within a rectangle bounded by Con IV on the North, lot 11 Murphy on the west, lot 8 Hoyle on the east and the south boundary of both Townships. In addition there are two claims in the N 1/4, lot 9 Con VI Whitney Twp. A list of claims and a map outlining their location are attached.

In 1982, 26 claims in 5 groups were staked in Murphy Twp. and added to the Bell Creek holdings. In addition 34 claims in 6 groups were optioned from Comstate Resources Ltd. in 1982. Airborne geological data revealed that the mineralized horizons did not strike into Comstate ground and the option was abandoned in December 1982.

ACCESS

The central part of the property is accessible by winter bush road from Hwy 101 at South Porcupine 5 miles to the south. The west claim groups are accessible from Hwy 655.

Choice of possible access roads to a shaft site include a route following the present bush road along the east side of the Bell Creek involving about 3 miles of road construction and a bridge a route from the southwest that would be longer but avoids a bridge, and a road from Owl Creek which would acquire close co-operation with Kidd Creek Mines.

PREVIOUS WORK

B. Rose (O.D.M. Vol. 33 Pt III, 1924) acknowledges reports of free gold associated with quartz veins in the S.E. part of Hoyle Twp. and reports seeing prospecting trenches during field work in 1923 but does not suggest when the work might have been done. The property was staked by Broulan Reef Mines Ltd. in 1958, and they carried out some diamond drilling and trenching on the Broulan-Marlhill zone.

In 1979 Rosario Resources Canada Limited optioned the Broulan and Marlhill ground and embarked on an exploration program in partnership with DuPont of Canada Exploration Ltd. The land was acquired as part of an ongoing program of exploring the western extension of Kidd Creek's Owl Creek zone begun in 1978. The program consisted of geophysical surveys (I.P. E.M. and Mag) followed by drilling. Between 1978 and 1982, 150 holes totalling 21,927 metres were drilled on various targets in the area. In 1982, 52 holes totalling 8530 metres were drilled.

GEOLOGY

The Bell Creek properties lie within an Archean volcanic complex of carbonated volcanic flows, volcano-clastics and chemical sediments. The rocks are poorly exposed and mapped, and may or may not be the folded equivalent of the productive Porcupine complex in Tisdale and Whitney Townships.

The sequence of rocks on the property, based on drill core, outcrop examinations, and geophysical data, is a series of weak to highly carbonated flows, fragmentals and tuffs, striking east-west and dipping steeply to the south. Geophysical data has disclosed, and drilling has confirmed, a number of narrow west-north-west trending pyritiferous-graphitic-argillite bands that appear to be sub-concordant to the stratigraphy, and provide useful marker horizons. The relationship of these units to the normal stratigraphy and the auriferous horizons has not been determined. To the north of our property the main volcanic sequence is flanked by a series of sediments consisting of conformable argillites and graphitic slates.

Carbonate alteration is widespread throughout the area, and affects most rock types to varying degrees. Because of the close association of carbonate with gold mineralization, the degree and type of alteration is particularly significant, and is a useful exploration guide. More detailed description of the gold-related carbonate alteration will be provided in the description of the mineralized zones.

Structurally the mineralized horizons appear to be strataform, striking slightly north of west and dipping 70-75° to the south. Some evidence of faulting is apparent in drill holes near Bell Creek, but lack of correlation from hole to hole suggests that faulting might parallel the north-south drill holes. There appears to be little or no offsetting in the area of the fault, but the wide spacing of the sections (+ 30 metres) may obscure subtle changes.

RESULTS OF 1982 PROGRAM

(a) FIELD WORK

Field work in 1982 consisted primarily of diamond drilling which was carried out continuously between January and October with stops for breakup in April and May, and the driller's vacation in July. Some maintenance was necessary on the existing winter road in addition to routine ploughing, and the bridge over Bell Creek was strengthened. During the summer months access was gained by Gotrack, and Timberjack for heavy equipment and helicopter for personnel and light gear.

Geological mapping was carried out on newly acquired claims, and some detailed mapping was done on the Marlhill showing. Reports covering these surveys are appended to this report. They are:

1. Lavery, M.E. Report on Geological Survey, Murphy Twp. Project 1202 Groups 03,10,12 & 13, June 1982.
2. Lavery, M.E. Report on Geological Survey Murphy & Hoyle Twps., Project 045 Group 04, October 1982.
3. Philipp, A. and Harron, G. Detailed Geology of Marlhill Trenches with map, August 1982.

(b) DIAMOND DRILLING

A total of 8530 metres were drilled in 1982 in 52 holes. Diamond drill logs for each hole are attached, along with cross sections. The cross sections may show new holes from the current drilling program in the Bell Creek zone but logs are unavailable.

The most significant results of the 1982 program were the development of a potential ore deposit on the North Zone, the establishment of continuity on the eastern portion of the Bell Creek Zone, and the extension of the Marlhill deposit to the northwest.

1. North Zone

The North Zone consists of two sub-parallel mineralized bands, designated the Upper and Lower Horizons, roughly 25 metres apart striking west-north-west and dipping 75° to the south. Host rocks of the Upper horizon are green fragmental tuffs, narrow basalt flows, and fine weakly graphitic tuff beds. The Lower Horizon is hosted by fine-grained graphitic argillite thought to be a fine grained tuff or ash.

The Upper horizon contains the best gold values and widths, and the mineralization is a concentration of pyrite, pyrrhotite, quartz veining and accessory chalcopyrite, sphalerite, arsenopyrite and tourmaline, within a carbonate envelope. The carbonate is calcitic and ranges from tan to grey in colour. Gold occurs primarily in free form usually with quartz, but occasionally in carbonated host rocks. About 30% of the gold is thought to be tied up in the sulphides. A persistent feature of the mineralized zone is a cherty quartz marker vein .1 to 1.0 metre wide that usually occurs near the top of the unit.

The mineralized zone averages about 4 metres in width but the enclosing carbonate envelope can vary from a metre or less to 20 metres in width. Aside from free gold itself the best indicator of gold in all of the Bell Creek deposits is the presence of arsenopyrite.

The occurrence has been tested for a length of 380 metres and to a depth of 220 metres and is open along strike and down dip. Of thirty-seven holes drilled into the Upper Horizon, all encountered the mineralized zone, and 27 returned values greater than 3 grams over 2 metres for an overall tenor of about 8.0 grams/ton. Drill logs cataloguing individual assays for each drill hole are appended to this report.

Like the Upper, gold mineralization in the Lower Horizon is associated with sulphides and quartz veining, but contains abundant graphite and less carbonate. The tenor of mineralization in the Lower Horizon is in the 3 to 4 gram per tonne range over widths from 1 to 7 metres. Other parallel mineralized zones occur in hanging wall of the North Zone. Although generally narrow, these zones can show reasonable continuity along strike, and might provide some ore if the North Zone is viable, despite their relatively low grade.

2. Bell Creek

Like the North Zone, the Bell Creek zone contains a number of mineralized horizons. The host rocks are carbonated tuffs, fragmental flows and komatiitic basalts. The various horizons are sub-parallel, about 25 metres apart, strike east-west, and dip to the south at 70°. Gold mineralization occurs in discrete zones of pyrite and quartz veins with accessory chalcopyrite, sphalerite, arsenopyrite, and tourmaline within a carbonate envelope. The carbonate is ankerite (ferro-dolomite) with calcite and graphite, ranging in colour from green tan to grey. Little free gold is seen in the core and it is assumed the bulk of the gold is tied up in the sulphides.

The density of drilling is not sufficient to establish continuity of the various mineralized horizons, but the potential of the best explored part of one zone appears to be in the order of 300,000 tonnes grading about 4 grams gold per tonne over a width of about 4 metres. This shoot has a length of about 150 metres and a depth of 175 metres.

3. Marlhill

The Marlhill deposit differs from the above both in setting and the mode of occurrence of the gold. The host rocks at Marlhill are carbonated pillow basalts, and gold occurs in the free form in a series of quartz veins having a saddle-vein configuration that both parallels and cross cuts the basalt. In general carbonate alternation becomes more intense near the veins where the rock is grey to tan in colour and contains cubic pyrite.

Two holes, 15 metres apart, drilled in 1982 on the northwestern extensions of the main Marlhill vein confirmed continuity of the vein. One hole yielded 35.42 grams over 0.9 metres, and the second 1.25 grams over 1 metre which illustrates the erratic nature of the zone.

(c) RESERVE POTENTIAL

Sufficient continuity exists from hole to hole down dip, and from section to section along strike to calculate a geological reserve potential on the North Zone. Calculations have been made using a number of different parameters, and the results are shown in an attached memorandum by the writer dated January 11, 1983. In the calculations the grade obtained in each hole was assigned an area of influence over a rectangle both longitudinally and in section extending halfway to the next hole, or less if the gap was excessive. The following table summarizes the geological reserve (Cut-off, 3 gms Au/Ton over 2 metres core length).

<u>Parameter</u>	<u>Metric Tonnes</u>	<u>Grade</u>
1. Undiluted		
Uncut	425,588	8.13 gms
Cut to 1 oz.	425,588	6.32 gms
2. Diluted (15% @ 0.22 mg Au/Ton)		
Uncut	489,387	7.10 gms
Cut to 1 oz.	489,387	5.23 gms

All assaying was done by Swastika Assay Laboratories, Swastika Ontario. A memo prepared by Mr. Gordon Yule dated December 10, 1982 describing the procedure used by Swastika is attached. A number of samples were re-run in order to establish the reliability of the assays. In addition the total metallic assay technique, which measures total gold present, was used on some samples. Results of these tests as well as a comparison with original assays are provided in an attached memorandum (G. Lauzier) These results indicate that the original assays may be as much as 8% low.

PROPOSED 1983 PROGRAM

The proposed 1983 Bell Creek exploration program will have a 3 pronged thrust. These are (a) exploration of outside properties, (b) fill-in and deep drilling on the North & Bell Creek zones, and (c) engineering studies and preparation for underground examination of the North Zone.

(A) OUTSIDE PROPERTIES

Outside properties refer to all groups other than the Broulan group containing the North and Bell Creek zones. These are:

1.(a) Allerston Property (8 claims)

Drilling in 1982 demonstrated the continuity of the North Zone 250 metres west onto the Allerston claims. Gold values up to 1.5 grams per ton over one metre were encountered.

Detailed magnetic and induced polarization surveys, followed by 4 diamond drill holes (600 metres) are planned to trace the North Zone further west.

1.(b) Rose Option (4 claims)

The Rose Option lies to the west of the Allerston claims and will be explored in conjunction with them. Line cutting, IP and magnetic surveys, and 2 holes (300 metres) are needed to evaluate the claims.

2. Stringer-Marlhill (6 claims)

Detailed induced polarization and magnetic surveys are planned to test the gap between the Stringer and Marlhill occurrences. Reconnaissance surveys in the past have outlined targets, but more precision is required before drilling, particularly in the area of Bell Creek where flooding prevented full coverage in the past. Two or three drill holes totalling 450 metres are planned to test the horizon.

3. Marlhill-Allerston (6 claims)

Like the western extension of the Marlhill Zone the eastern extension has not been adequately tested, and it is proposed to survey the area north of the graphitic marker with IP and magnetic equipment to outline targets. Initially 2 holes (400 metres) are planned to test the potential of the group.

4. Chartrand (4 claims)

This group lies at the west end of the Bell Creek properties and was acquired because a promising airborne conductor occurs on it. Limited ground geophysics and one hole (150 metres) will adequately test the conductor.

5. Wetmore (10 claims)

This group was acquired in 1982 on the basis of geological similarity to the Bell Creek zone. The claim group lies immediately north of a major carbonatized ultramafic belt similar to the outcrops south of the Bell Creek zone, and mineralization will be sought north of this unit as at Bell Creek.

Magnetic, electromagnetic and induced polarization surveys will be used to outline targets, and two holes (400 metres) have been allotted to follow up the results of the surveys.

Table of Work on Outside Properties

<u>Property</u>	<u>Type of Work</u>					
	L.C. km	I.P. km	Mag km	E.M. km	D.D.H. km	Metres
Allerston	6	7	6	-	4	600
Rose	6	6	6	-	2	300
Chartrand	1	-	1	1	1	150
Wetmore	9	8	8	4	2	400
Stringer]						
-Marlhill]	2	3	6	-	2-3	450
Marlhill]						
-Allerston]	6	6	6	-	2	400
	30	30	33	5	13	2,300

B. NORTH & BELL CREEK ZONE DRILLING

1. North Zone

It is estimated that about eight fill-in holes totalling 2800 metres will be required to provide absolute confidence in the outline of the North Zone. As these holes would not add materially to the reserves, six deep holes totalling 2100 metres are planned to intersect the mineralization at about 260 metres below surface. In addition a pilot hole to 300 metres on the shaft site is planned.

2. Bell Creek - East Zone

A 10 hole, 7500 metre program is planned to outline areas of higher grade gold mineralization within the Bell Creek zone.

3. Broulan - Marlhill Zone

Five holes totalling 500 metres are proposed to continue tracing the Marlhill zone to the northwest and to depth.

TABLE OF WORK ON DEPOSITS

<u>Occurrence</u>	<u>D.D.H.</u>	<u>Metres</u>
North Zone a) fill-in holes	8	2800
b) deep holes	6	2100
c) shaft site	1	300
Bell Creek East	10	1500
Broulan-Marlhill	5	500
	30	7,200

C. MINING STUDIES

In preparation for an underground examination and sampling program on the North Zone engineering studies and preparatory work has to be undertaken. The following work will be undertaken early in 1983 preparatory to beginning underground work in the fall.

- Photographic survey to outline best access for road and power line
- Directional surveying on 5 to 6 holes to determine their deflection
- Grouting of all surface holes
- Ground water survey
- Rock mechanic testing
- Geostatistical analysis
- Engineering design
- Metallurgical testing
- Environmental studies
- Permit requirements
- Road construction
- Power line requirements
- Commencement or road construction
- Preparing shaft site, collaring shaft & start of shaft sinking

Field work will begin early in 1983. The scale of the eventual program will depend on the results obtained in the drilling, the results of engineering studies, the speed at which permits are granted, and the availability of qualified personnel contractors and equipment. The program, as presented, assumes that the North Zone proves to be a viable deposit and anticipates no procedural delays.

COST ESTIMATES FOR 1983 PROGRAM

A. PRELIMINARY EXPLORATION

1. Geophysical & Geological Surveys

Line Cutting - 30 km X \$200 = \$6,000
Induced Polarization 30 km X 600 = \$18,000
Magnetometer 30 km X 100 = 3,000
Electromagnetic 5 km X 200 = 1,000
Geological Surveys 30 km X 400 \$12,000

\$40,000

2. Diamond Drilling

(a) Outside Properties - 2300 metres
(b) North Zone - 5200 metres
(c) Bell Creek East - 1500 metres
(d) Broulan Marlhill - 500 metres
9500 metres

All-in-costs estimated @ \$95.80 X 9500 = \$910,100

3. Metallurgical Tests

Metallurgical tests to determine recoveries will be conducted on drill core samples 50,000

Preliminary Exploration Total \$1,000,100

B. ADVANCED EXPLORATION

1. Mine Planning

Airphoto surveys, mosaics	\$ 5,000
Gyro log survey of 5-6 holes	5,000
Grout all surface holes	15,000
Ground water survey & pump test	10,000
Rock mechanic testing	3,000
Geostatistical analysis	15,000
Engineering design plant	
Mine layout, contract bid proposal (shaft and related surface facilities), equipment specifications and costing, etc.	
This item should cover expenses of retaining engineering company as well as in-house Amax charges	\$ 100,000

2. Environmental Studies

Determination of, and application for, permits
to proceed with road construction, mine
development and site reclamation \$ 10,000

3. Road and Bridge Construction

Estimated cost of an access road and
bridge across Bell Creek \$ 200,000

4. Underground Exploration

All-in cost of site preparation
building mining plant, collaring and
sinking shaft-\$8,200/metre 100 metre
completion in 1983 \$ 820,000

B. Total Advanced Exploration \$ 1,183,000
A. Total Preliminary Exploration 1,000,100

\$ 2,183,100

MARLHILL-BROULAN REEF GEOLOGICAL MAP

NOTES UNDER GEOLOGY

All the principal auriferous quartz veins definitely crosscut bedding and schistosity and dip between 50-70° to the east. Silicification, as narrow quartz stringers or veins, usually show on the higher west wall of the crosscutting veins. These narrow veins parallel bedding and are oriented at a large angle to the main veins. Exposed in the higher footwall side of the main 'M Vein' in Trench #3 as well as in the drill cores from both walls of the vein, are occurrences of a fragmental rock in close proximity with the vein. These fragments are now thought to have been produced during the emplacement of this vein rather than representing a separate fragmental host horizon following some deformed anticlinal stratigraphy.

The only safe and measurable plunging features which can be seen in the Marlhill area are in relation with pillows (which resemble boudins in schistose rock) and which plunge steeply to the east at 80°. All pillows seen show tops to the south with the exclusion of those questionable few in Trench #8.

Bell Creek - North Zone Geological Reserve Estimate

An estimate has been made of the geological reserves of the Upper Horizon North Zone deposit, Bell Creek. Twenty seven intersections were used in the calculations. (Holes 119, 117, 115, 114, 120, 113, 118, 132, 101, 122, 148, 149, M81-45, 147, 133, 123, 127, 134, 151, 146, 125, 141, 124, 135, 143, 129, 142.) A cutoff of 3.00 grams over 2 metres (core length) was used. True widths, dilution, and dilution grade were calculated for each intersections. The results are as follows:

A. UNDILUTED (Widest intersections)

	Metric Tonnes	Grade	Short tons	Grade
1. Uncut Grade	425588	8.13 gms.	469131	0.237 opt.
2. Cut to 1.0 oz.	425588	5.99 gms.	469131	0.175 opt.
3. Cut to 1.25 oz.	425588	6.32 gms.	469131	0.184 opt.

B. UNDILUTED (Higher Grade Intersections Hole 134 & 146)

1. Uncut grade	388862	8.78 gms.	428526	0.256 opt.
2. Cut to 1.0 oz.	388862	6.43 gms.	428526	0.187 opt.
3. Cut to 1.25 oz.	388862	6.80 gms.	428526	0.198 opt.

C. DILUTED (Widest Intersection) 15% @0.22 gms./tonne

1. Uncut Grade	489387	7.10 gms.	539305	0.207 opt.
2. Cut to 1.0 oz.	489387	5.23 gms.	539305	0.153 opt.
3. Cut to 1.25 oz.	489387	5.23 gms.	539305	0.161 opt.

D. DILUTED (Higher Grade Intersections in holes 134&146)

1. Uncut Grade	446342	7.68 gms.	491868	0.223 opt.
2. Cut to 1.0 oz.	446342	5.64 gms.	491868	0.164 opt.
3. Cut to 1.25 oz.	446342	5.96 gms.	491868	0.173 opt.

E. Average True Width

- a. Undiluted - Widest intersection - 3.87 m. (12.7')
- b. Undiluted - Higher grade intersection - 3.87 m. (11.6')
- d. Diluted - Widest intersection - 4.40 m. (14.4')
- c. Diluted - Higher grade intersection - 4.04 m. (13.3')

F. Potential

Considering the full vertical range down dip of 216 metres (708.5 feet) the potential of the deposit is 2266 tonnes per vertical metre (76 tons per vertical foot). However more accurate estimate of the potential would be to consider only that portion of the deposit that has been drilled on 30 metre centres. Thus for a vertical depth of 150 metres the potential is 2694 tonnes per vertical metre (905 tons per vertical foot).

MEMORANDUM

TO: Germain

FROM: Gord

SUBJECT: SWASTIKA LABORATORIES ASSAY PROCEDURE

DATE: December 10, 1982

PREPARATION

"Samples are crushed through a #1 Woodstock crusher and further reduced to approximately 6-mesh using a Sturtevant Roll. The rolls are then cleaned with a combined wire brush and air jets. Samples weighing less than 1 pound are crushed through a Sturtevant Roll Jaw crusher. A Jones Riffle is used to cut a 400 gram portion for pulverizing. When requested the reject portion is bagged and stored.

After reducing to nominal 100-mesh with a Braun pulverizer, the samples are thoroughly blended and sent to the fire assay department." (Lebel, 1980)

FIRE ASSAY

"A 0.5 assay ton portion (14,538 grams) is used for fire assaying. This process results in a particle of gold which in the normal assay method, is weighed on a Huesser assay balance with a sensitivity of 0.0025 milligrams at best or 0.005 ounces per ton." (Lebel, 1980)

ATOMIC ABSORPTION

"To lower detection limits for geochemical work or where required, the gold particle or doré bead is dissolved and determined by Atomic Absorption Spectrophotometry." (Lebel, 1980)

Using pleirs, the 0.5 mg doré bead is picked off the fused button and transferred to #04 loors parting cups in a metal tray. The bead is dissolved by adding approximately 4 mls of parting acid (1 part nitric acid and 7 parts water) and then taken to dryness over a boiling water bath. Then 5.4 mls of 40% aqua regia is added and each cup covered and cooked for twenty (20) minutes then cooled."

"The concentration of gold now in solution is measured in micrograms/ml by Atomic Absorption Spectrophotometry relative to standards made from proof gold.

This dissolved gold after the collecting of previous metal with a fire assay fusion, should not be confused with the Ketone Extraction - A.A. methods." (Lebel, 1980)

CHECKS

"Constant checking is done by comparing the weight finish against the A.A. finish and also by the assaying of standard samples such as Canmet MA-1 and Amax's Au7 and Au9. Repeat or check samples are done regularly. Results from replicate determinations using both methods of "finish" agree favourably. By far, the greatest spreads occur when free gold is present making sampling difficult." (Lebel, 1980)

ASSAY RESULTS REPORTED

"With a 0.5 assay ton sample and a final volume of 5.0 mls, the instrument reading in micrograms/ml are multiplied by a factor of 0.01 to give ounces per ton, or by 0.34286 to give ppm (parts per million)." (Lebel, 1980)

To check the homogeneity of gold mineralization, additional pulps are taken from the reject. Appendix I illustrates this multiple pulp determination utilized on several Amax gold projects.

MAP #3	GEOLOGICAL SURVEY - GROUP 1202-12	- 1:5000

SUMMARY

During June 1982, geological surveys were completed on twenty-three (23) claims in three groups and part of a fourth group, within south central Murphy township, District of Cochrane, Ontario.

The claim groups are completely covered by overburden which varies from sand, gravel and boulders on the Murphy esker to muskeg and spruce bog in the lower areas flanking the esker.

The bedrock geology underlying the claim groups is interpreted from previous drilling and geophysics to be mafic to intermediate volcanics of the lower formations of the Tisdale Group and sediments of the lower formations of the Porcupine Group.

CONCLUSIONS AND RECOMMENDATIONS

The geological surveys confirmed that no outcrop exposure exists on the claim groups leading to the following recommendations:

1. All previously completed airborne and ground geophysical data should be re-assessed in an attempt to locate structural targets which may be proximal to potentially favourable areas for gold deposition.
2. All known geological data should be compiled for the southern part of Murphy township to assist in the location of target areas.
3. Priority rating of located target areas should be followed up with an integrated program of line-cutting, proton magnetometer, electromagnetic and possibly induced polarization surveys to further define drill targets.
4. Diamond core drill evaluation of defined targets.

INTRODUCTION

Detailed geological surveys were completed on twenty-three (23) claims contained in three groups and part of a fourth group, within Murphy township during June 1982. The claim numbers are: P-393148, P-393161 - 393165 inclusive, P-393736, P-594595 - 594598 inclusive, P-619352 - 619354 inclusive, P-641625 - 641626 inclusive, P-641778 - 641781 inclusive, P-641788 - 641789 inclusive and P-636457, containing approximately 368 hectares of land. All the claims are recorded in the name of Amax of Canada Limited.

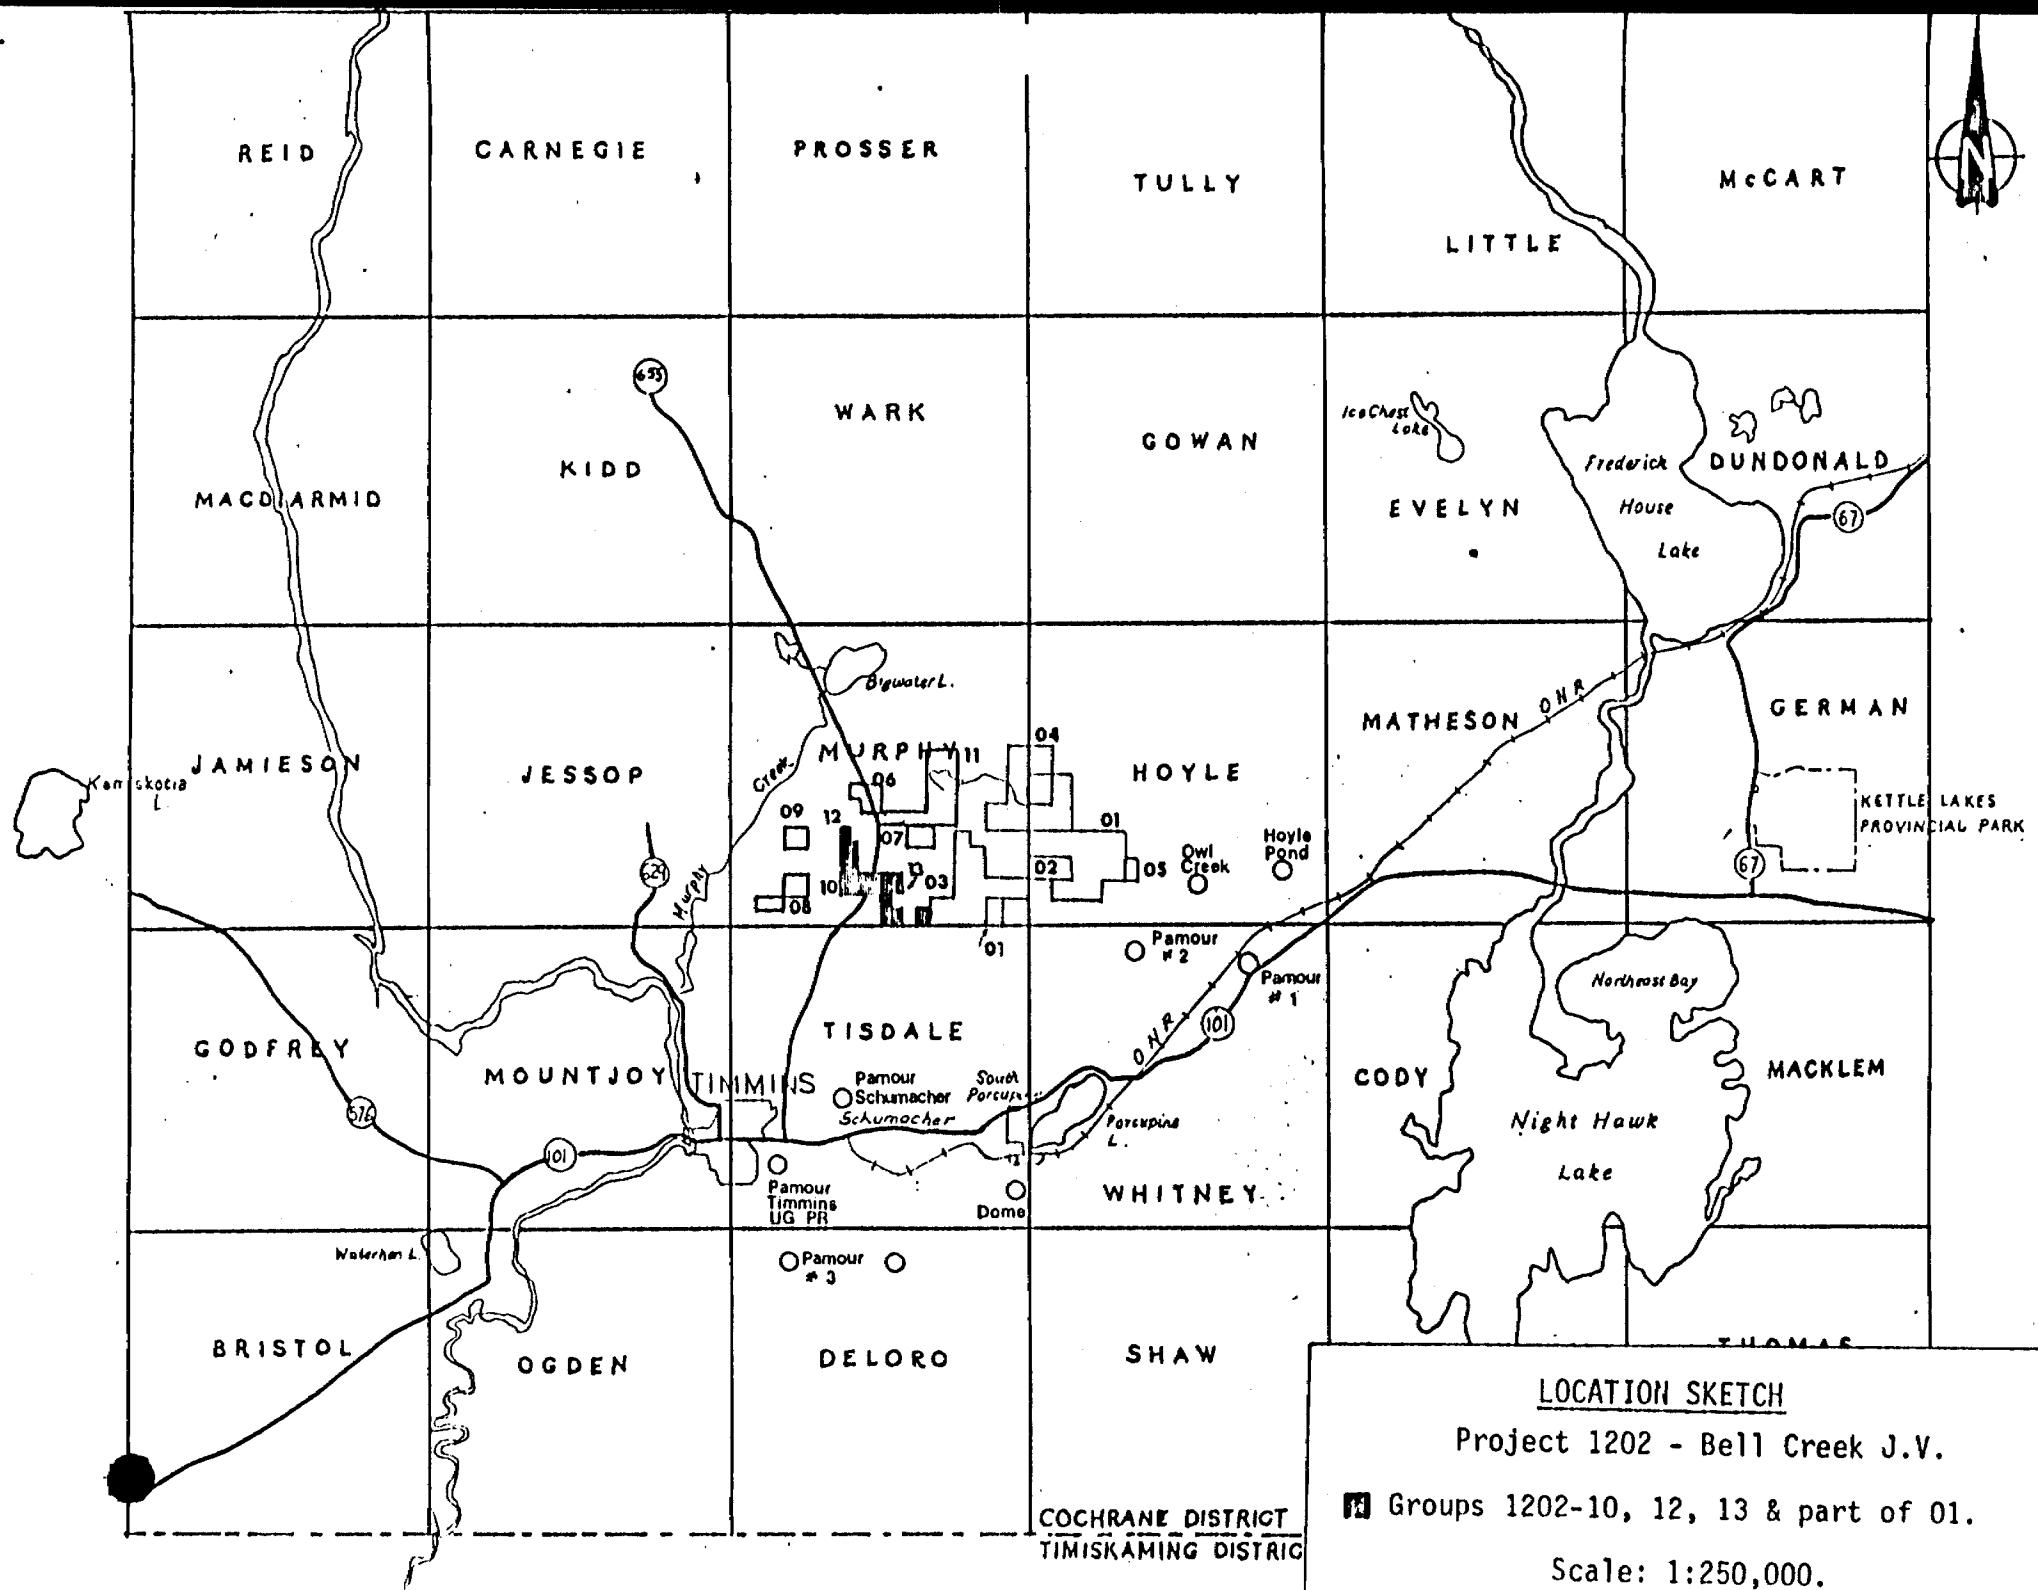

The purpose of the geological survey was to locate and map any outcrop, which exists on the claim groups. Special attention was paid in areas where electromagnetic conductive zones were located by a previously completed airborne survey.

The surveys are the initial phase of a multi-phase exploration program designed to locate economically exploitable ore deposits.

LOCATION AND ACCESS

The surveyed claim groups occupy parts of Lots 5, 6, 7 and 8, concessions I and II within south-central Murphy township, District of Cochrane, Ontario, approximately 12 kilometers north-north-east of the Timmins City centre.

Access onto the claim groups is possible by motor vehicle north from Highway 101 along Highway 655 and then either on foot for a short distance along well cut out concession lines or along a good gravel road which follows a natural gas pipeline south-eastward. Figure 1 shows the ease of access onto these claim groups.

TOPOGRAPHY AND RESOURCES

The relief on the claim groups is moderate. The north-south Murphy esker is the prominent topographic feature in the area with the land sloping east and westward down into large swampy areas on its flanks.

Wherever the esker passes through the claim groups commercial stands of jack pine thrive. Birch, poplar and some spruce are found on the side slopes of the esker. Tag alder and black spruce are found in the large swampy areas on either side of the esker.

Commercial gravel deposits exist along the Murphy esker and gravel is currently being taken from the series of pits along Highway 655 within claim group 1202-10.

PREVIOUS WORK

All the claim groups have been held intermittently by a variety of owners since the early 1930's. The greatest amount of activity occurred on these claims during and through the years directly following the 1964 Kidd Creek Cu-Zn-Ag discovery to the north in Kidd township. It is known from privately gathered information that all the claim groups were included in larger airborne electromagnetic and magnetic surveys completed by Mespi Mines, McIntyre Mines and Hollinger Mines, but unfortunately none of these surveys have been submitted to the government assessment files.

One diamond drill hole on current claim P-594596 could be found in the assessment files. This hole was completed by Renzy Mines in 1969 to evaluate a conductive zone which was found to be caused by graphite within a sedimentary series of rocks.

During the spring of 1981, Comstate Resources completed an airborne Input survey over most of Murphy township. This survey included all the land within the claim blocks covered in this report.

SURVEY METHOD

The surveys were performed by M. E. Lavery, assisted by M. Petruk and A. Verville. Air photos at a scale of 1:15,840, roads and power lines were used for control. All traverse lines were run using pace and compass at 100 metre intervals except where beaver ponds or extremely wet swamps made this impossible. In the latter case, traverses were run around these areas and carried on.

REGIONAL GEOLOGY

The rocks of the Timmins area are of Archean Age with the exception of a few diabase dykes which are late Precambrian. The volcanic rocks of the Timmins area consist of the older Deloro Group and the overlying Tisdale Group. These rocks are predominately mafic but do range in composition from ultramafic to felsic and include associated sedimentary horizons. A thick sequence of metasediments termed the Porcupine Group is in part contemporaneous and in part overlies the Tisdale Group. Igneous bodies ranging in composition from ultramafic to felsic intrude the area. A few north to north-east trending diabase dykes of late Precambrian age intrude all rock types of the area.

A major structural break, the Destor-Porcupine Fault, trends north-east across the area. Other regional structures include the Burrows-Benedict and the Montreal River fault systems. All the rocks, with the exception of the diabases, are tightly folded and sheared in a dominantly north-east direction.

The volcanic and sedimentary rocks of the area have undergone regional metamorphism to the lower and middle greenschist facies.

Tholeiitic Metavolcanics

Massive to medium grained flows, pillowed flows and flow breccia, minor tuff, lapilli tuff and breccia

Komatiitic Metavolcanics

Peridotite, olivine spinifex, carbonate and talc alteration

PROPERTY GEOLOGY

There was no outcrop exposure on any of the claim groups examined.

The southern part of Murphy township, including the examined claim groups, is interpreted from previous drilling and geo-physics to be underlain by the lower formations of the Tisdale Group and the lower formations of the Porcupine Group. The rock types would include peridotite, komatiitic basalt, tholeiitic basalt, andesite, dacite, greywacke and argillite.

The Burrows-Benedict Fault is projected to strike north-north-westerly through claim P-636457 off-setting the stratigraphy approximately 800 metres with a sinistral movement.

Respectfully submitted,

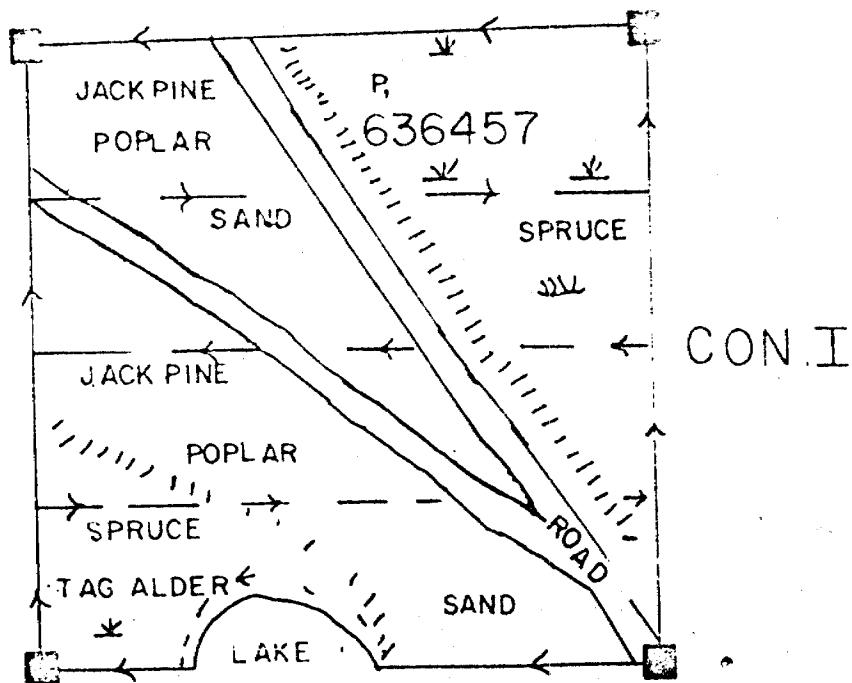

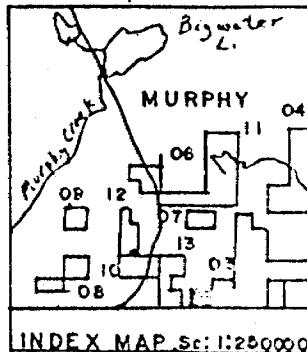

Timmins, Ontario
June 1982

SUMMARY

During July and August, 1982, a geological survey was completed over thirty-two (32) contiguous claims in one group which straddles the Murphy-Hoyle township line, district of Cochrane, Ontario.

The claim group is completely covered by overburden which varies from a few small sandy knolls to predominately muskeg and spruce bog.

The bedrock geology underlying the claim group is interpreted, from geophysics and previous drilling in the area, as mafic to intermediate volcanics and tuffs of the lower formations of the Tisdale Group and sediments of the lower formations of the Porcupine Group.

CONCLUSIONS AND RECOMMENDATIONS

The geological survey confirmed that no outcrop exposure exists on the claim group leading to the following recommendations:

1. All previously completed airborne and ground geophysical data should be re-assessed in an attempt to locate structural targets which may be proximal to potentially favourable areas for gold deposition.
2. All known geological data should be compiled for the central parts of Murphy and Hoyle townships to assist in the location of target areas.
3. Priority rating of located target areas should be followed-up with an integrated program of linecutting, proton magnetometer, electromagnetic and possibly induced polarization surveys to further define drill targets.
4. Diamond core drill evaluation of defined targets.

INTRODUCTION

A detailed geological survey was completed over thirty-two (32) contiguous claims in one group which straddles the Murphy-Hoyle township line during July and August of 1982. The claim numbers are P-516562-565, P-516572-575, P-525270-277, P-525303-306, P-540402-405, P-546519 and P-546522-528 inclusive containing approximately 512 hectares of land. All the claims are recorded in the name of Amax of Canada Limited.

The purpose of the geological survey was to locate and map any outcrop which exists on the claims in an attempt to correlate this data with rock exposures and diamond drill information to the south.

The survey is the initial phase of a multi-phase exploration program designed to locate economically exploitable ore deposits.

LOCATION AND ACCESS

The surveyed claims occupy parts of Concession III and the south half of IV, Lots 11 and 12, Hoyle township and Lots 1 and 2, Murphy township, district of Cochrane Ontario. The property is located approximately 15 kilometres northeast of the Timmins city centre.

LOCATION MAP

SCALE: 1" = 60 MILES

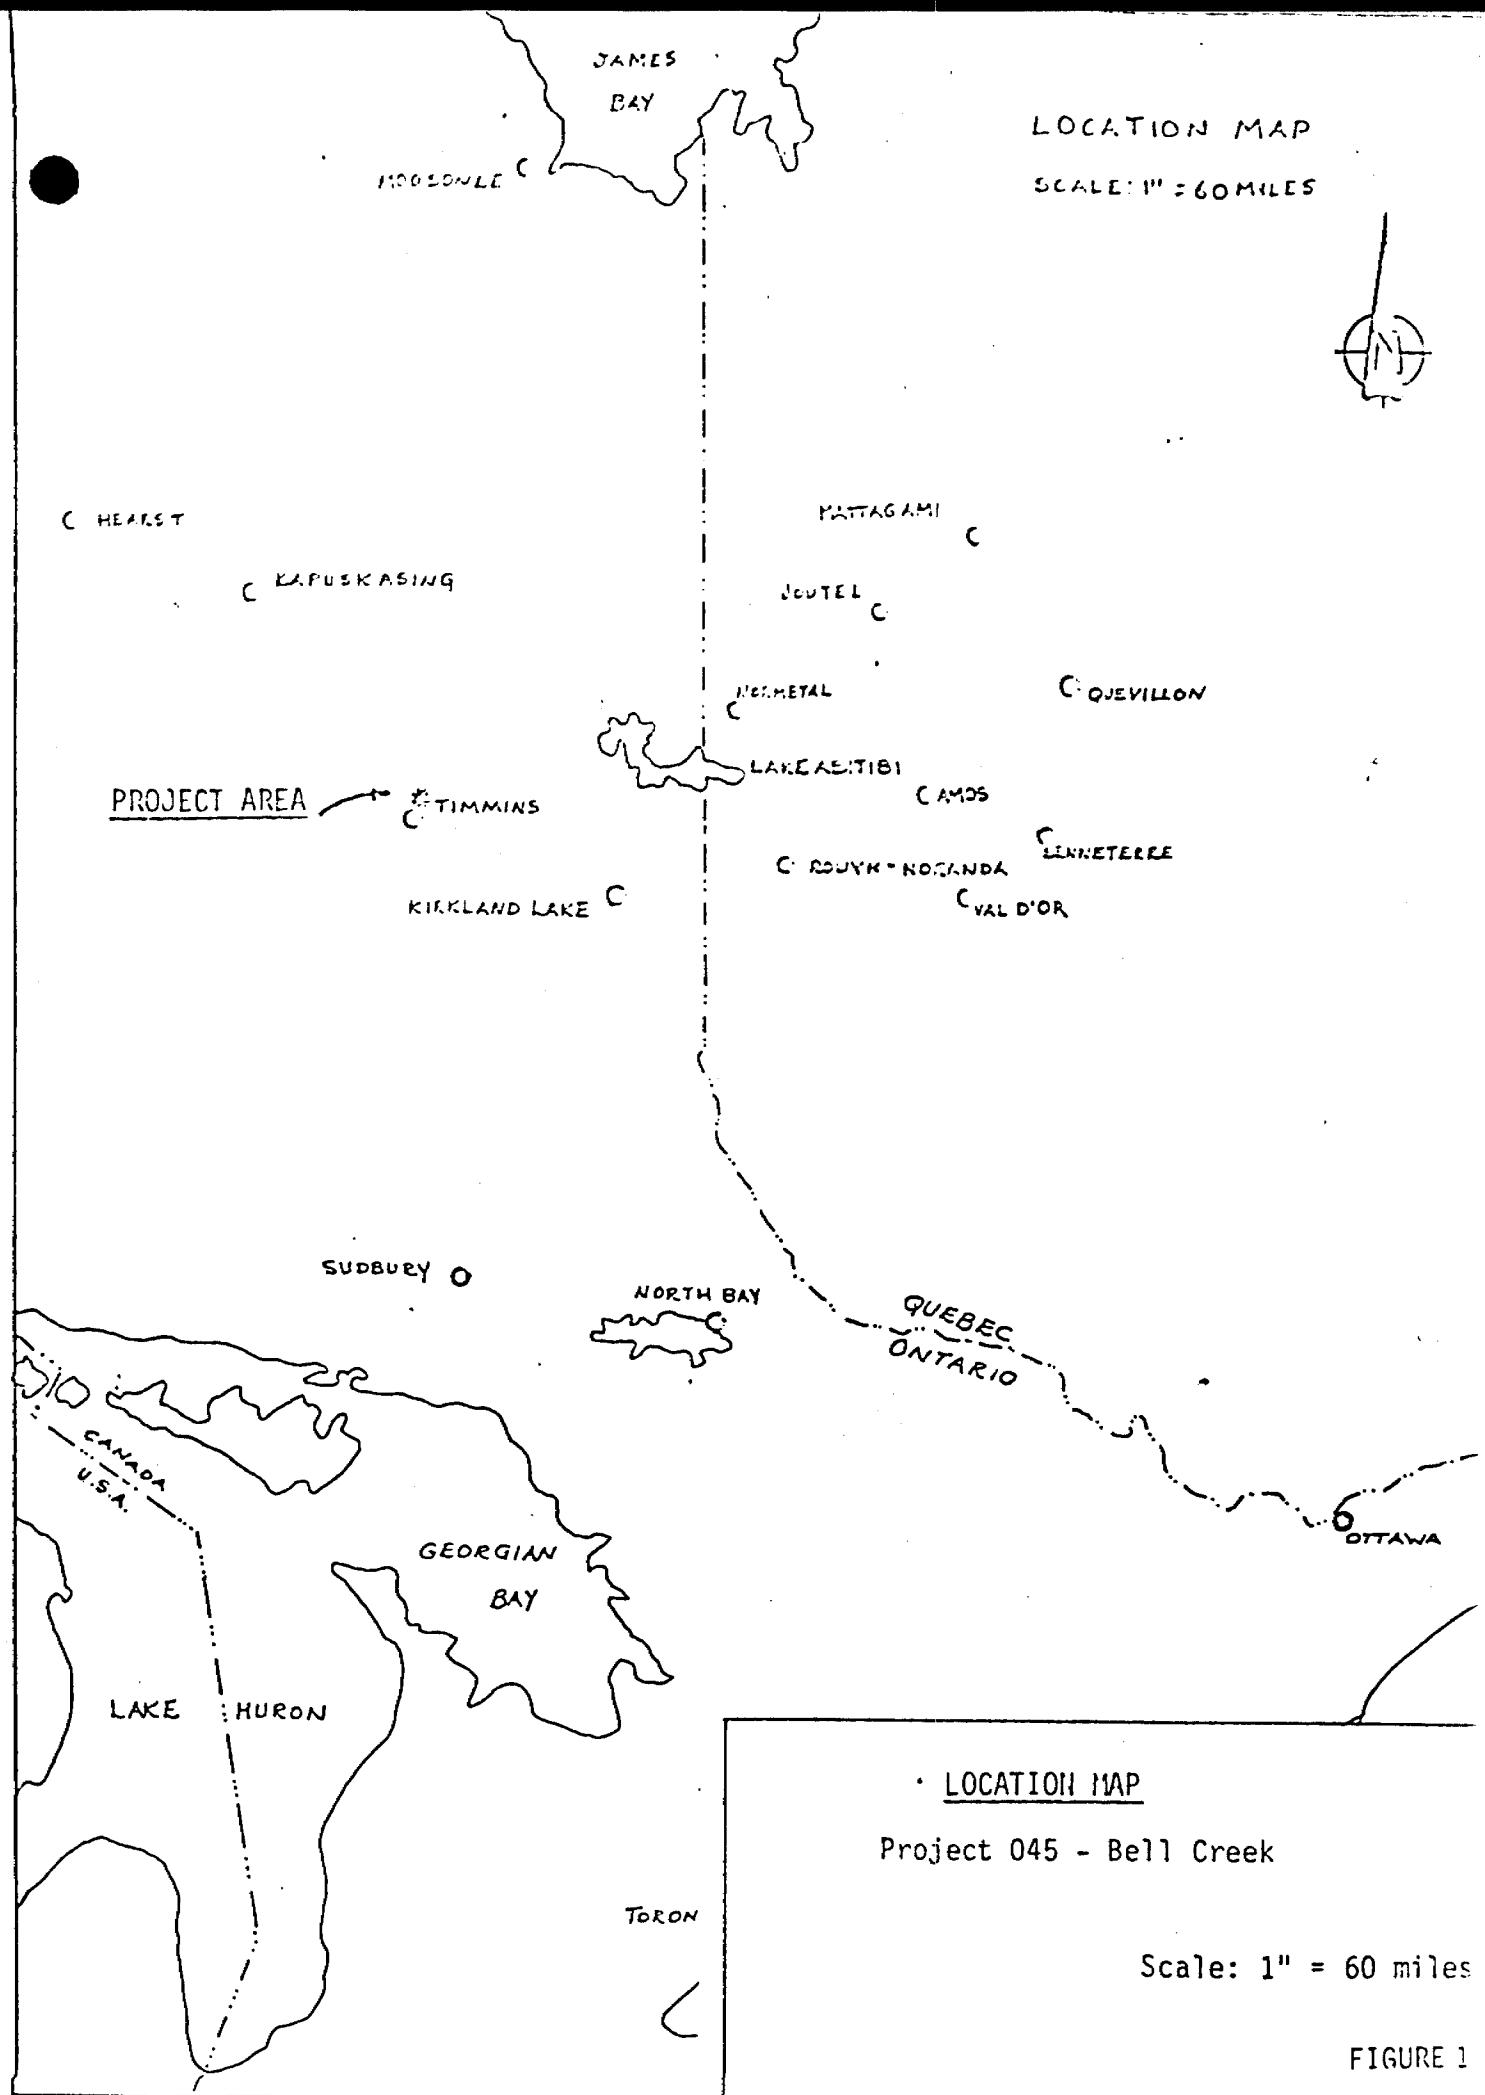

FIGURE 1

Access onto the property is possible by motor vehicle, north from Highway 101 along Highway 655 to approximately 1.5 kilometres north of the Miller Paving site and then northeastward along a good gravel road to the common concession line between Concession II and III and hence eastward along the concession line for 2 kilometres to the claim group.

The Kidd Creek spur line of the O.N.R. crosses the northeast corner of the claim group but access along the line is too lengthy to be practical.

(TOPOGRAPHY AND RESOURCES

The relief of the claim group is flat with only a few low sandy knolls rising above the otherwise low flat muskeg and spruce bog. Little Goose Creek and Bell Creek are the prominent topographic features crossing the claim group.

A gravel permit covers claims P-546524 and P-546528 along part of the northern boundary of the claim group. The gravel from this area was used during the construction of the Kidd Creek railway spur line.

The prominent vegetation on the claim group is black spruce which grows everywhere except on the sandy knolls where birch, poplar and tag alder predominate.

FIGURE 3

PREVIOUS WORK

All the claims have been held intermittently by a variety of owners since the early 1930's. The greatest amount of activity occurred on these claims during and through the years directly following the 1964 Kidd Creek Cu-Zn-Au discovery to the northwest in Kidd township. It is known from privately gathered information that all the claims were included in larger airborne electromagnetic and magnetic surveys completed by Mespi Mines, McIntyre Mines and Hollinger Mines but unfortunately, none of these surveys have been submitted to the government assessment files.

Rosario Resources Canada Limited completed an integrated program of linecutting, electromagnetic and proton magnetometer surveys over the south half of Concession III, Lots 1 and 2, Murphy township and Lots 11 and 12, Hoyle township during 1979. A conductive trend was located along the southern boundary of the claim group.

A diamond drill hole was completed on claim P-516575 to evaluate this conductor and intersected sediments to the north of a graphitic argillite conductor and carbonated mafic volcanics to the south. A second diamond drill hole was completed on claim P-525306 with a sequence of sediments and tuffs intersected. No significant gold values were reported from either of these holes.

During the spring of 1981, Comstate Resources completed an airborne INPUT survey over most of Murphy and Hoyle townships. This survey included the claim group covered in this report.

SURVEY METHOD.

The survey was completed by M.E. Lavery, assisted by M. Petruk and A. Verville. Air photos at a scale of 1:15,840, concession lines and creeks were used for control while mapping. All traverse lines were run using pace and compass at 100 metre intervals except where beaver ponds or extremely wet swamps made this impossible. In the latter case, traverses were run around these areas and carried on.

REGIONAL GEOLOGY

The rocks of the Timmins area are of Archean Age with the exception of a few diabase dykes which are late Precambrian. The volcanic rocks of the Timmins area consist of the older Deloro Group and the overlying Tisdale Group. These rocks are predominantly mafic but do range in composition from ultramafic to felsic and include associated sedimentary horizons. A thick

METAVOLCANICS AND METASEDIMENTS

Metasediments
 Conglomerate, lithic wacke, iron formation
 Metavolcanics
 Felsic Calc-alkalic metavolcanics
 Massive, fine grained flows, tuff, lapilli tuff, breccia
 Mafic Calc-alkalic metavolcanics
 Massive, fine grained flows, pillowed flows, tuff, lapilli tuff and breccia, sheared, carbonated pyroclastics
 Tholeiitic Metavolcanics
 Massive to medium grained flows, pillowed flows and flow breccia, minor tuff, lapilli tuff and breccia
 Komatiitic Metavolcanics
 Peridotite, olivine spinifex, carbonate and talc alteration

sequence of metasediments termed the Porcupine Group is in part contemporaneous and in part overlies the Tisdale Group. Igneous bodies ranging in composition from ultramafic to felsic intrude the area. A few north to northeast-trending diabase dykes of late Precambrian age intrude all rock types of the area.

A major structural break, the Destor-Porcupine Fault, trends northeast across the area. Other regional structures include the Burrows-Benedict and the Montreal River fault systems. All the rocks, with the exception of the diabases, are tightly folded and sheared in a dominantly north-east direction.

The volcanic and sedimentary rocks of the area have undergone regional metamorphism to the lower and middle green-schist facies.

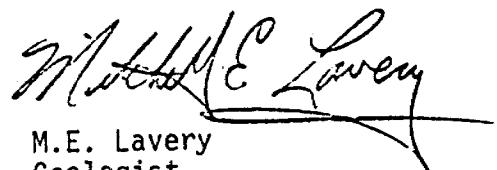

PROPERTY GEOLOGY

There was no outcrop exposure on any of the claims within the claim group.

The central part of Murphy and Hoyle townships covered by claim group 045-04 is interpreted from previous drilling and geophysics to be underlain by the lower formations of the Tisdale Group and the lower formations of the Porcupine Group. The rock

types would include peridotite, komatiitic basalt, tholeiitic basalt, andesite, greywacke, argillite and related tuffs. Carbonate alteration occurs sporadically throughout all these rock types. The area is cross-cut by a few north-south diabase dykes which sometimes are off-set by later faults.

Respectfully submitted,

M.E. Lavery

Core Location	Hoyle - Camp site					3	150.0m	-48°	-40°
Remarks	2.3 metres wide upper Au horizon was cut at 118.0 metres vertical depth. No VG was noted but horizon contains a fair sulphide content. Poor drill set-up in creeks made hole direction go off section by about 5° (N5°E). VG occurs in small zone at 134.5m.
