SUMMARY

A 17 Km. grid was cut and 22 Km. of Maxmin surveys and 6.3 Km. of detailed V.E.M. surveys defined two separate conductors. The shorter conductor was drilled by Mespi Mines in 1968 and found to be caused by graphitic tuffs in a highly fractured felsic to intermediate volcanic rock assemblage. The longer conductor is at least 1200 meters (4,000 feet) long, as defined by V.E.M. and has two stronger zones within its length. The two stronger zones are both 400 meters (1,200 feet) long as defined by the 600 foot cable Maxmin survey. The northern H.E.M. zone was also detected by the 400 foot cable Maxmin survey. This latter zone represents an untested conductor within a geologically favourable area and should be considered as a first priority drill target.

INTRODUCTION

This report deals with electromagnetic and magnetic surveys covering the MacDiarmid-2 property, Project 824-02. The eight contiguous claims were acquired by Amax Potash Limited on February 7, 1977 to cover an Input anomaly system located by the 1970 Input Mark V survey flown for Hollinger. It covers 17 separate anomalies as defined by the Input Mark VI A survey flown for Amax in May 1977.

The Magnetometer and H.E.M. surveys were completed by Geoex Limited personnel and the V.E.M. detailed survey was completed by Amax personnel in March 1977.

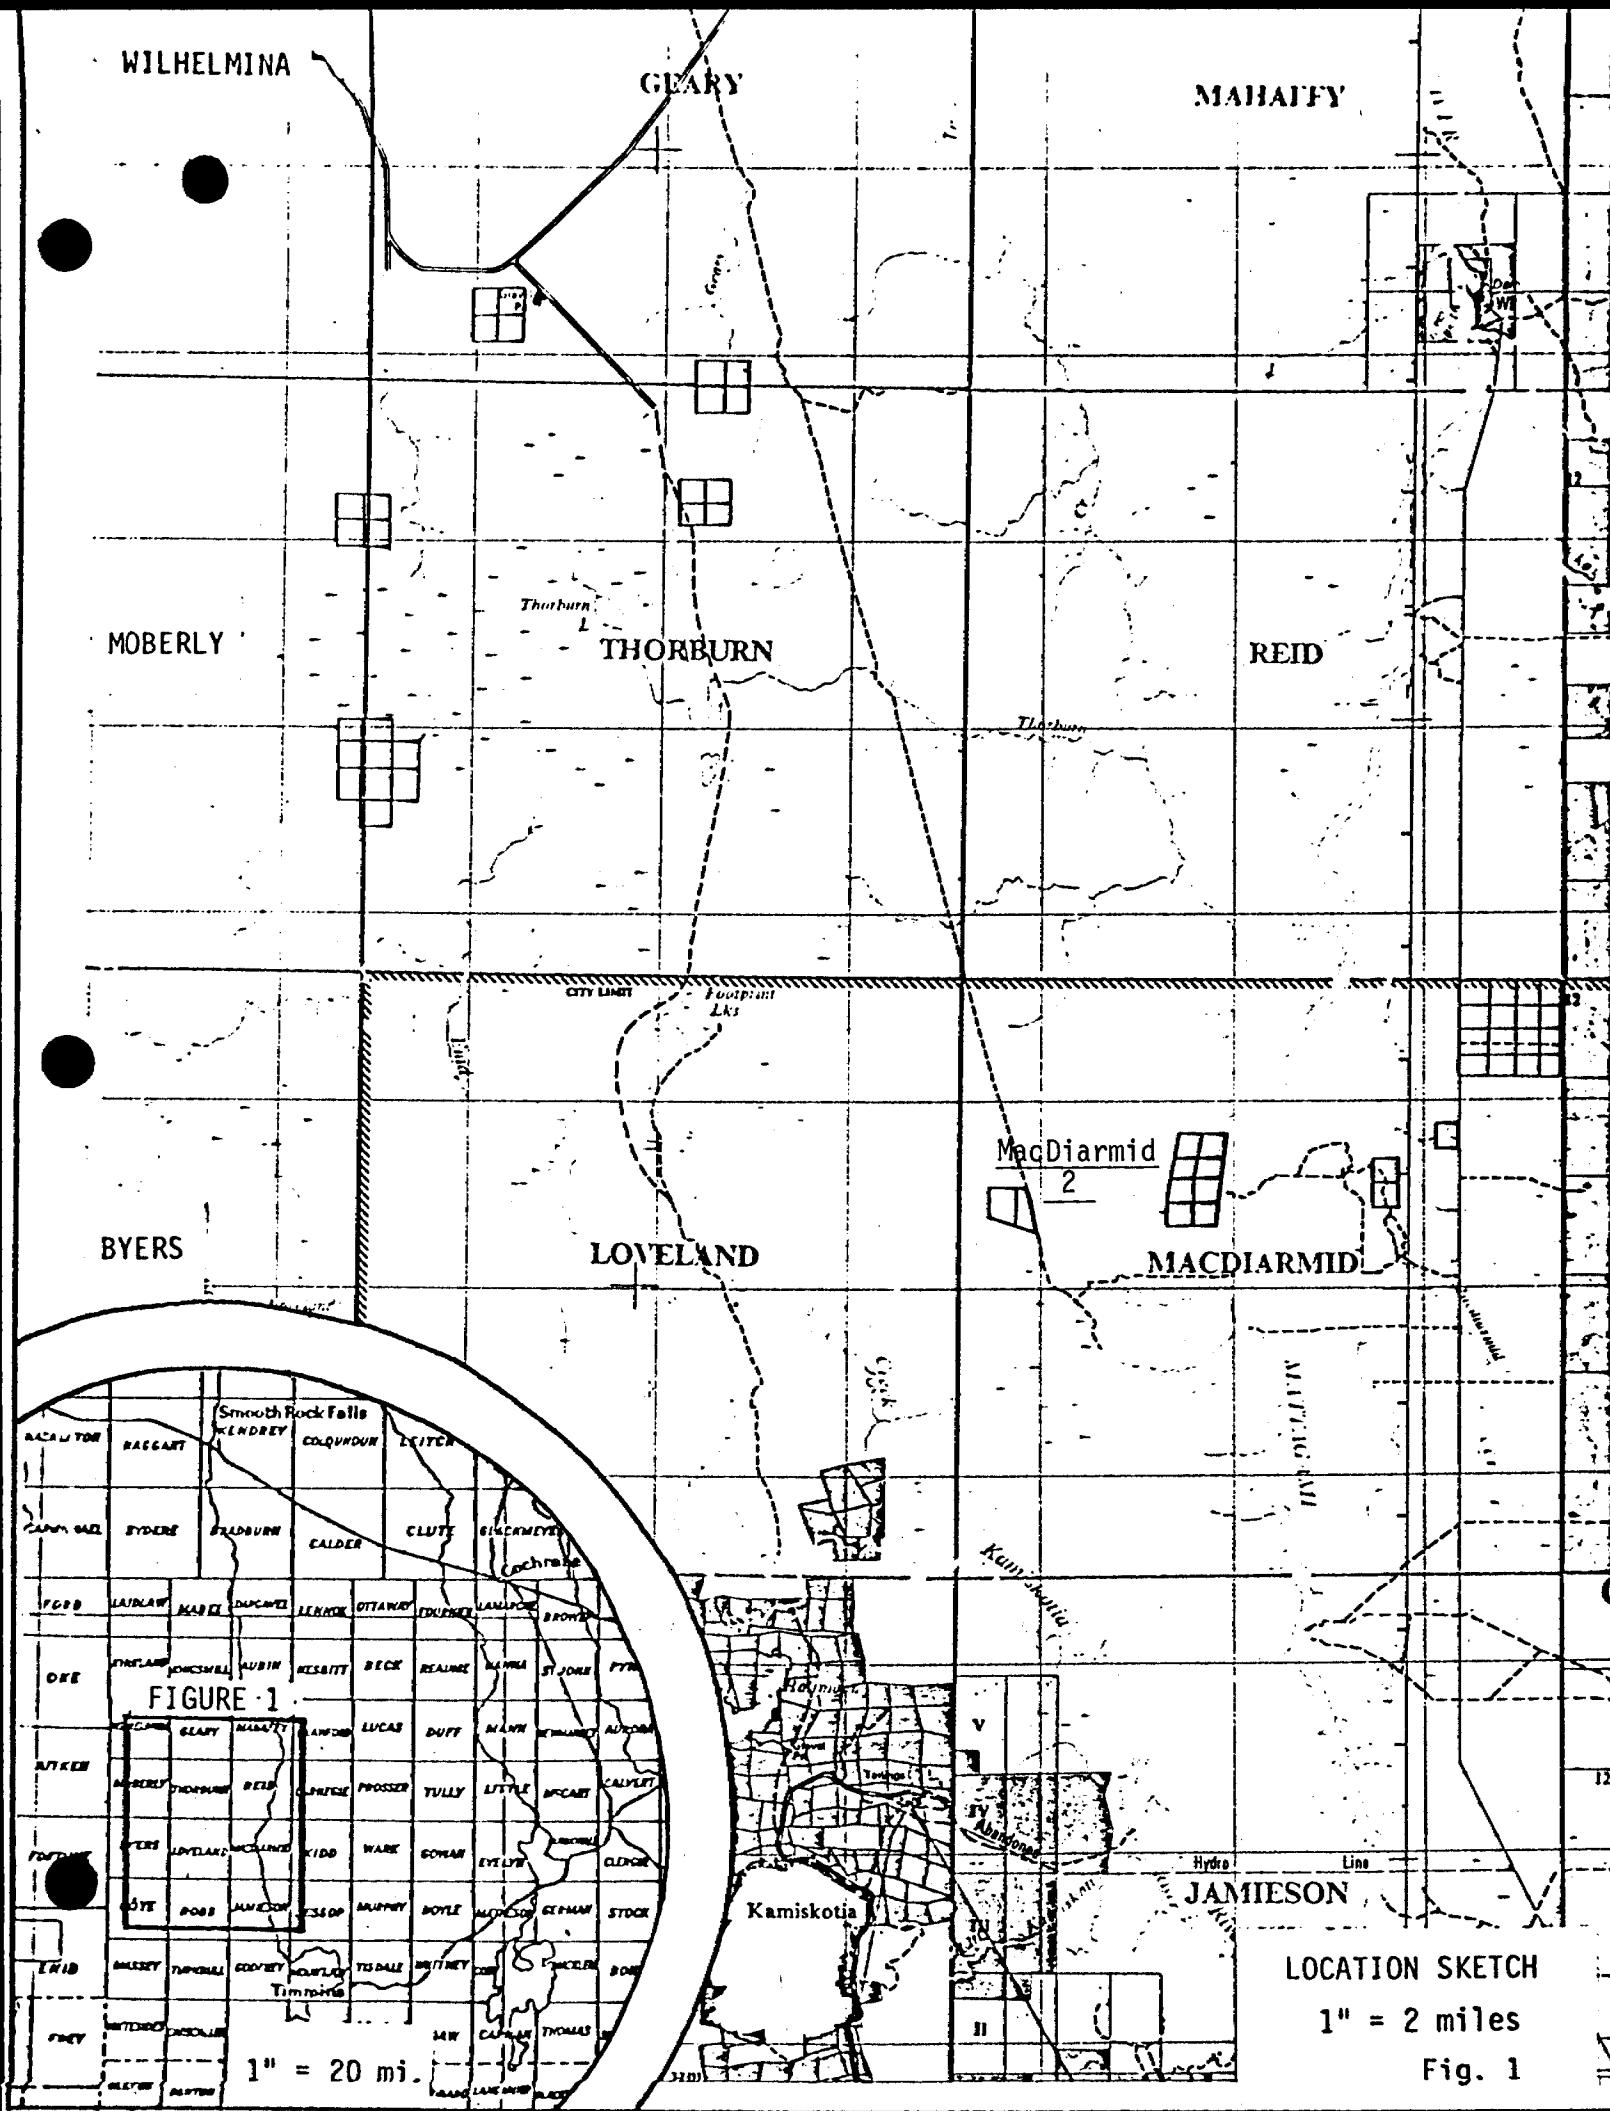

LOCATION AND ACCESS

The property is located approximately 17 miles northwest of Timmins along the west bank of the Mattagami River in MacDiarmid township (Figure 1).

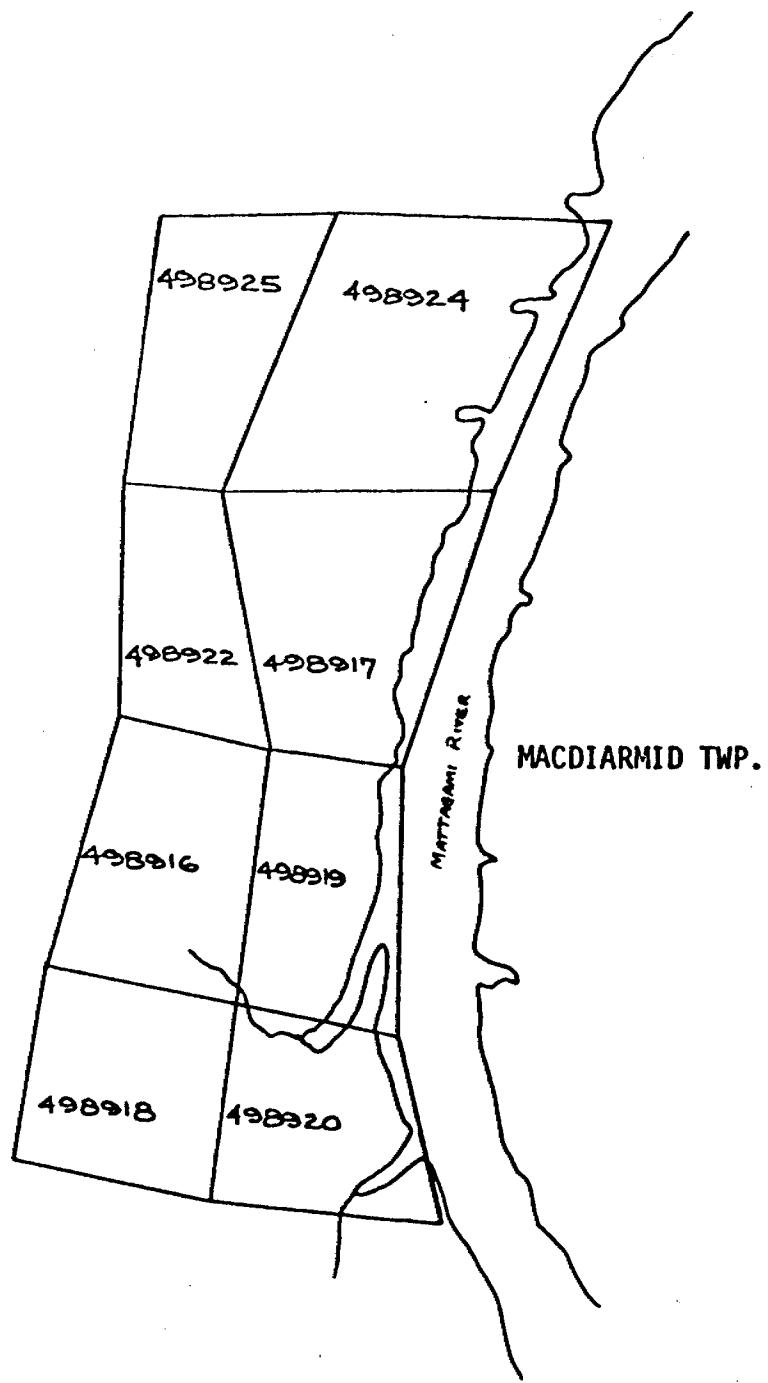

Summer access is by boat launched in the Mattagami River at Sandy Falls. Winter access is by snowmobile from the Sandy Falls hydro road which extends south to Timmins. Helicopter access is available from Timmins.

TOPOGRAPHY AND RESOURCES

The west bank of the river forms an abrupt topographic break with numerous narrow creek valleys crossing the property. The flat hills are covered with mixed poplar, spruce and balsam, and the valleys support stunted spruce and alders. The northwest corner of the property is poorly drained and is covered by dense alders and mixed spruce and cedar. No attempts have been made to harvest the timber on the property. Clay and gravel overburden to a depth of 180 feet should be expected.

CLAIM MAP
PROJECT 324-02

MACDIARMID-02
Macdiarmid Township

Scale: 1" = $\frac{1}{4}$ mile

GENERAL GEOLOGY

Three data points are available within the claim group. Gabbro was intersected by Hollinger in the southern end of the group within the weakly conductive A.E.M. zones. An old drill set-up was found on the northern boundary. Drill logs indicate basic volcanics and chloritic schists with minor graphite in the north. An outcrop of dacite tuff was found just south of our northern claim boundary on the river in claim P-498924.

PREVIOUS WORK

Hollinger detected an A.E.M. response similar to ours in their Input Mark V survey in 1970 (Timmins File T-560). Their follow-up included ground geophysics using the Ronka Mark III system with a 300 foot coil separation, and recommendations for detailed EM-17 work. One drill hole was apparently spotted on the best of the Ronka targets and there is no record of the EM-17 survey. The 200 feet of overburden in that drill hole is sufficient to invalidate the results of the entire survey.

Mattagami Lake Mines flew the area using Turair in 1971 (T-1514). A broad zone of weak conductivity at the southwest corner of the claim group and one strong anomaly was located on our claim P-498919 near the river. No further work has been filed for assessment credit.

Chance Mining flew the area in 1964 (T-840) and found two weakly conductive zones coincident with that found by Mattagami Lake Mines at the southwest corner of our group. No follow-up work was filed for assessment credit.

SURVEY METHODS

An Apex Maxmin II instrument was used with frequencies of 444 and 1777 Hz and coil separation of 600 feet. Detail H.E.M. work at 400 foot cable separation was completed over parts of the grid. Further V.E.M. detail using the Crone large loop instrument with frequencies of 390 and 1800 Hz was completed in the anomalous areas. The H.E.M. surveys were completed by Geoex Limited and the V.E.M. survey by Amax personnel in March 1978.

The magnetometer survey was completed by Geoex Limited personnel in February and March 1978, using a Scintrex MP-2 proton magnetometer.

The surveys were conducted on a picket line grid with 25 meter stations along lines 125 meters apart.

RESULTS AND DISCUSSIONS

Electromagnetic Surveys (see Map 1, 2 and 3; back pocket)

The H.E.M. surveys defined three conductors, two of which have been joined up by the V.E.M. work. The following parameters have been defined for the three conductors:

CONDUCTOR "A" - northwest corner; lines 875N, 1000N and 1125N

Strike: Approximately north-south

Length: Approximately 300 meters (1,000 feet)

Width: Narrow

Depth: Approximately 60 meters (200 feet)

Dip: Approximately 75° easterly

Conductivity: Approximately 150 mhos

Coincident Magnetics: within a broad magnetic low

CONDUCTOR "B" - central conductor; lines 250N, 375N and 500N

Strike: 010°
Length: Approximately 375 meters (1230 feet)
Width: Narrow
Depth: Approximately 85 meters (280 feet)
Dip: Vertical
Conductivity: 150 mhos
Coincident Magnetics: within and parallel to a large mag high trend

CONDUCTOR "C" - southern conductor; lines 375S, 250S and 125S

Strike: 010°
Length: Approximately 250 meters (820 feet)
Width: Narrow
Depth: Approximately 45 meters (150 feet)
Dip: Vertical
Conductivity: 20 mhos
Coincident Magnetics: same mag relationship as conductor "B"

The V.E.M. survey joined conductors "B" and "C" and extended the conductor north from conductor "B". The V.E.M. conductor axis is coincident with the H.E.M. axes.

Magnetic Survey (see Map 4; back pocket)

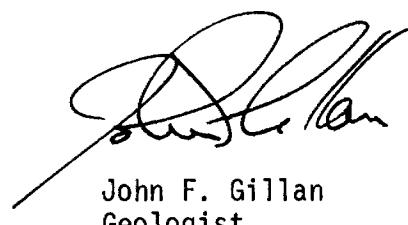

The magnetometer survey outlined an elongated mag high which extends north-south with the highest magnetics in the southeast corner. Maximum relief is approximately 1500 gammas. The mag high branches into two narrow zones at line 500N which diverges from the main north trend.

The altered ultramafic flow and serpentinized peridotite rock assemblage drilled by Hollinger lies within a magnetically low area.

CONCLUSIONS AND RECOMMENDATIONS

1. Two zones of conductivity have been defined by electro-magnetic surveys.
2. The north zone (conductor "A") was drilled and found to be due to graphite within intermediate volcanic rocks. Minor amounts of chalcopyrite and pyrite were noted.
3. The south zone (conductors "B" and "C") is parallel to the magnetic trend and represents an untested conductor in a geologically favourable environment.

It is recommended that conductor "B" should be drilled as soon as logistically feasible.

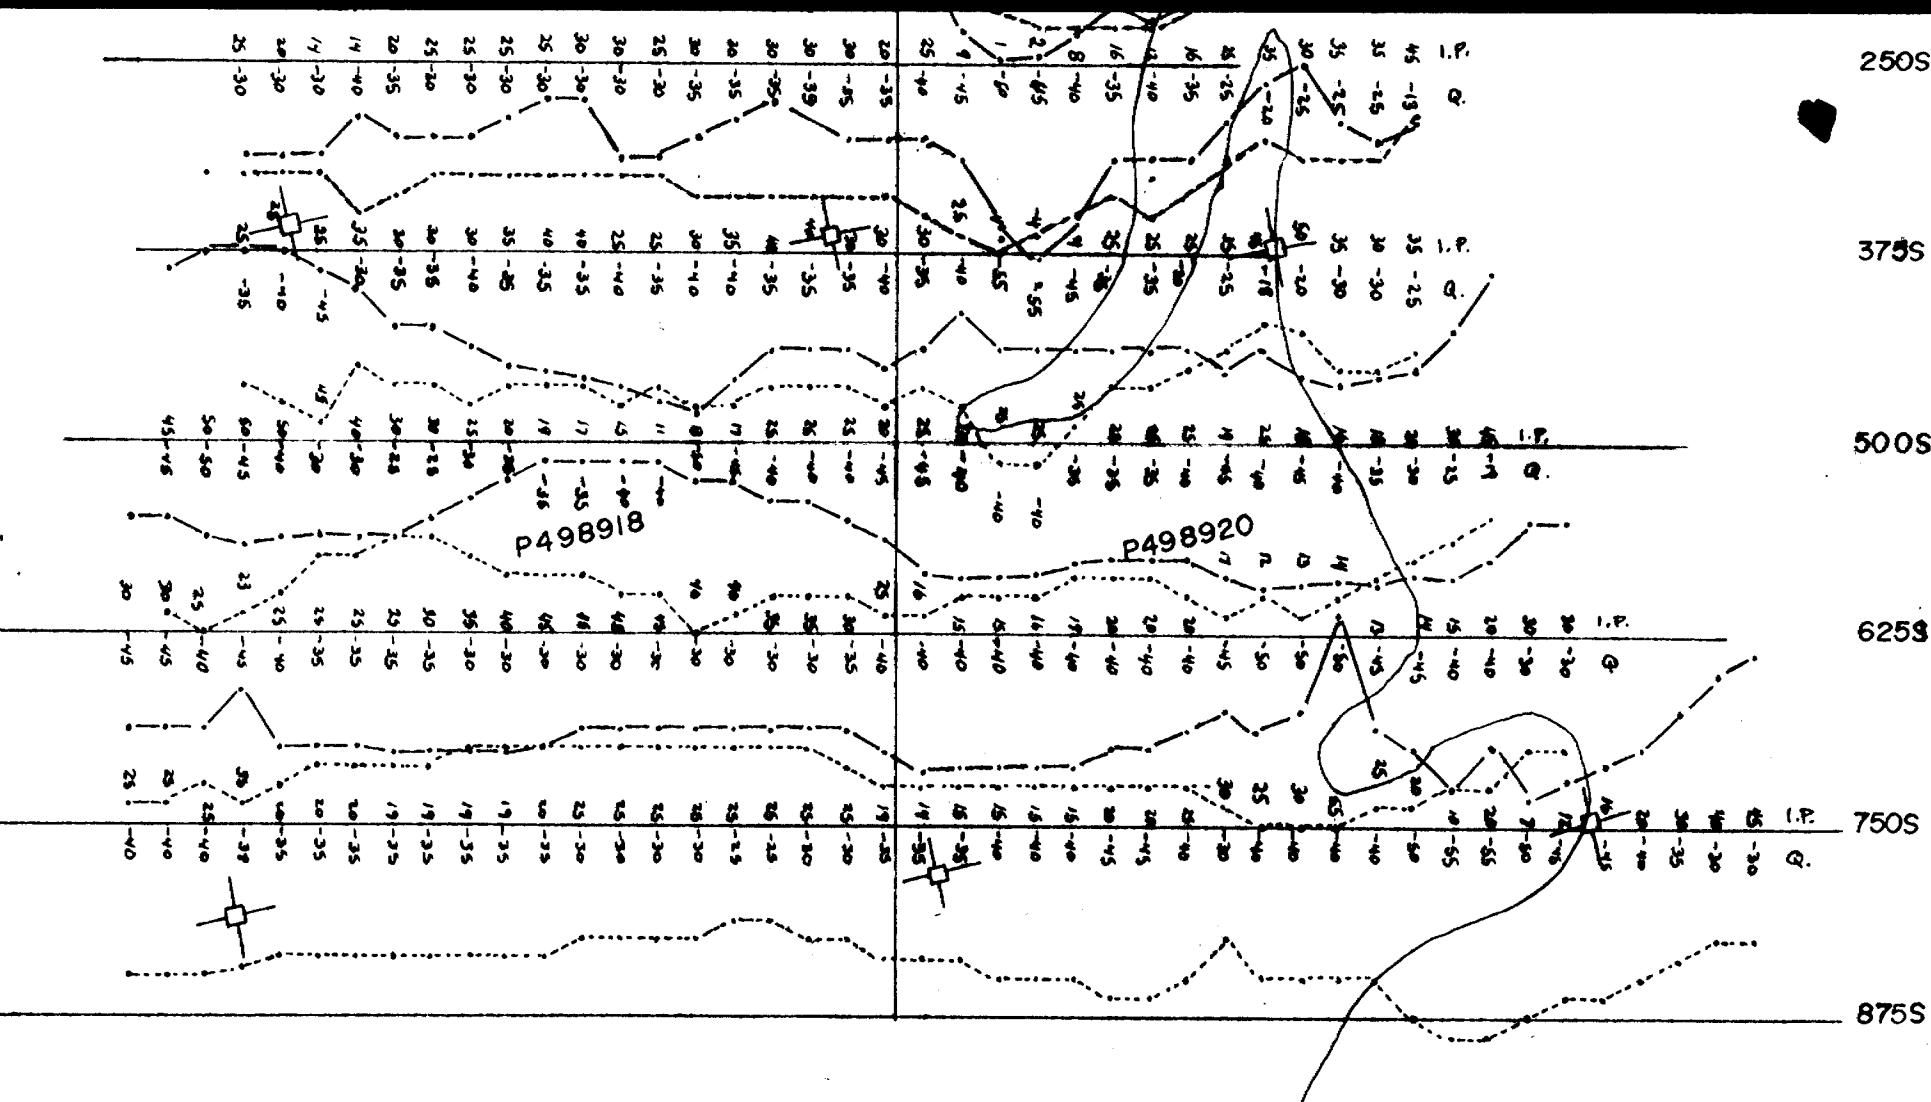

John F. Gillan
Geologist
