Summary

Mineral exploration programs, including geological mapping, relogging and sampling of historic diamond drill core and geophysical surveys were carried out on the Mann Property from March to May 2001. Todd Keast, P.Geo was contracted to map the exposures on the Frederick House River on the property(Fig. 5) and to log or relog and sample core from nine historic diamond drill holes(Appendix B). R. J. Daigle and Geoserve Canada Inc. were contracted to cut lines and carry out a total field magnetic survey and a Time Domain IP survey to add to previous surveys on the property. 14.8 km. of lines were cut at 100 metre intervals and chained and picketed at 25 metre intervals. All new lines and several old lines were surveyed for total field magnetics and 7.5 km of lines were surveyed with Time Domain I.P. A separate report documenting the geophysical surveys accompanies this report(Daigle,2001). The total cost of these programs was $28,658.46.

The geological and geophysical work outlined a number of areas with the potential for enrichment in PGE's. A 1000 metre diamond drilling program is recommended test these areas.

Introduction

The Mann Property is being explored for Platinum Group Metals (PGM) by a joint venture between Broadlands Resources, Ltd. and Tres-Or Resources Ltd. with Tres-Or as the operator. Todd Keast, P.Geo. was contracted by Tres-Or to carry out a program of geological mapping, relogging and sampling nine historic diamond drill holes, supervising geophysical surveys and tendering a diamond drill contract to several local drill companies. R.J. Daigle and Geoserve Canada were contracted to carry out total field magnetic and Time Domain I.P. surveys over part of the property and compile this data with previous surveys to cover the whole property. The author was commissioned by Laura Lee Duffett, P.Geo. President of Tres-Or, to integrate the geological and geophysical programs and prepare a report documenting this work.

Property Location and Access

The Mann Property is located 47 km north of Timmins, Ontario, within Duff Township and Mann Township, of the Porcupine Mining Division. The claims are situated in the northwest corner of Mann Township and the northeast corner of Duff Township. The project is centered at 48°52'N and 81°02'E NTS 42A/NW.

The Mann Project is easily accessed by travelling north along Hwy 11 approximately 14 km northwest of the Iroqouis Falls turnoff (Hwy 578), to the Potter Station turnoff. Travel west along this road for 19 km until you reach a bridge, which crosses the Frederick House River. This is the central portion of the Mann Project. A number of trails access the north and west portions of the property.

General Location Map

Scale: as shown	Coords: geographical	Figure: 1
Date: October, 2001	By: d.s.d./a.g.b.	

Topogaphy and Climate

The topography of the Mann Project is flat to gently rolling. Outcrop exposure is low, approximately 1-2% except along the Frederick House River where outcrop is continuous in the southern part of the property and intermittent in the north. The majority of the property is covered by spruce bog, thick alder and muskeg. Drainage is controlled by a number of small creeks, which generally drain to the northwest into the Frederick House River, which in turn drains north. The climate of the project area is warm and dry in the summer months from May through to September, and cold and snowy from November to March. Temperatures range from +30 Celsius in the summer to –30 Celsius in the winter.

Property and Ownership

The Mann Project consists of 19 contiguous claims covering 304 ha, situated within Mann Township and Duff Township of the Porcupine Mining Division(Fig 2). Leonard Hill of South Porcupine, Ontario, is the registered holder (100%) of these claims. Tres-Or can earn a 100% interest in the property by making cash and stock payments with Leonard Hill retaining a royalty. Broadlands can earn a 75% interest in the claims by making stock and cash payments to Tres-Or. Claim abstract summaries are included in Appendix A. and a list of claims follows:

Claim Map

Scale: 1 : 20,000	Coords: UTM zone 17	Figure 2
Date: August, 2001	By: d.s.d./a.g.b.	

Regional Geology

The exploration targets on the Mann property are platinum group element mineralization and nickel-copper sulphide mineralization, hosted within specific layers of the Mann ultramafic intrusion. Ni-Cu sulphide deposits are generally associated with ultramafic and gabbroic volcanic rocks of both intrusive and extrusive nature. The Ni-Cu sulphide deposits are within specific sulphide rich horizons, which are conductive due to the high sulphide content. A summary of Ni-Cu sulphide deposits from the Timmins Area is included in Table 2.

Table 2 – Ni Cu Sulphide Deposits of the Timmins Area

Deposit Name	Grade	Tonnes
Texmont	0.93% Ni,Cu N.A.	3,190,000
Langmuir (1&2)	2.09% Ni,0.08%Cu	1,600,00
Alexo	4.5% Ni,0.50%Cu	52,000
Redstone	2.39%Ni,0.09%Cu	1,220,000
Montcalm	1.44%Ni,0.68%Cu	3,560,000

The Mann Project is situated within the Mann intrusive complex of the Abitibi subprovince. It is located at the northwestern end of the belt of ultramafic/mafic intrusive and extrusive rocks included in the Stoughton-Roquemaure assemblage, as recognized by Jackson and Fyon (1991). The geology of Mann Township was mapped by Satterly (1959), and Hunt and Richard (1980), and included in the regional studies of Jensen and Langford (1985).

The Mann intrusive complex is very large, with a strike length greater than 40 km and a thickness greater than 1.5 km (Fig 3). The complex occurs approximately 28 km northeast of the Kidd Creek massive sulphide deposit, within the northwestern end of a belt of unltramafic/mafic intrusive and extrusive rocks included in the Kidd-Munro and Stoughton-Roquemaure assemblages. In addition to ultramafic and mafic intrusions, the major lithologies in the area are predominantly northwestly striking mafic metavolcanics accompanied by minor intermediate metavolcanics and interflow sediments (Fig 4). The Mann complex is folded along a west to northwest trending fold axis. The metamorphic grade is mid-greenschist facies.

Property Geology

The property geology is based upon work by government agencies, work in the area by previous operators, and a research paper by Good, Crocket, and Barnet (1997). Regional mapping and limited diamond drilling on the project indicates the presence of the ultramafic intrusion. Diamond drilling to the north of the project area has intersected anomalous Ni-Cu mineralization in ultramafic flows, intrusions and sediments.

Details of the size and composition of the Mann intrusive complex are poorly understood due to limited outcrop and structural complexity. Three major rock types have been documented on the Mann property: peridotite, clinopyroxenite, and gabbro (Fig 5).

Mann Property

Porcupine M.D., Ontario, Canada

Regional Geology

Scale: as shown	Coords: UTM zone 17	Figure 3
Date: August, 2001	By: d.s.d./a.g.b.	

Peridotite

The peridotite is predominately wehrlite with minor serpentinite. The wehrlite is hetradcumulate and consists of medium-grained subrounded olivine and interstital subophitic clinopyroxene (augite), subhedral chromite and minor anhedral orthopyroxene. Serpentinite occurs locally and consists of >95% serpentine abd 1-5% fine grained magnetite.

Clinopyroxenite

Based upon limited outcrop exposure and one diamond drill hole intersection, the clinopyroxenite member in the mapped section is between 14 and 30 m thick with a strike length of 500 m, south-southeast. The clinopyroxenite is an adcumulate composed of >90% clinopyroxene (augite).

Gabbro

The gabbro unit is medium grained and consists of approximately equal portions of subhedral plagioclase and anhedral clinopyroxene, along with minor amounts of orthopyroxene, quartz, epidote and magnetite.

Research by Good, Crocket and Barnet on the central portion of the Mann Project concluded that "Clinopyroxenite in the mafic-ultramafic complex in Mann township apparently crystallized from magma similar to that which formed the sulphide bearing komattiite at the Ni-Cu Alexo Deposit". This research indicated that exploration potential exists for the development of Ni-Cu sulphide mineralization in the Mann Complex, specifically on the Mann Property. PGE mineralization identified on the Mann Project is hosted within ultramafic rocks including clinopyroxenite and peridotite. The PGE mineralization is not associated with zones of heavy sulphide mineralization, as observed at other PGE showings and deposits. The apparent controls on the transport and deposition of PGE are similar to those of other PGE deposits of hydrothermal origin, such as the platiniferous pipes of the Bushveld Complex.

Mineral Exploration History

The Mann Project has received limited exploration for a variety of commodities over the past twenty years. Past work on the property has included government mapping and airborne geophysical surveys. Assessment work filed by previous operators on the property is limited. A summary of previous work programs is included below.

Holmer Gold Mines (1973)

In 1973, Holmer Gold Mines completed vertical electromagnetic (VEM) surveys and completed one diamond drill hole to test one of the EM anomalies. The drill hold intersected peridotite, pyroxenite and ultramafic porphyry. A summary of the hole is included in Table 3. Mineralization to account for the VEM anomaly was not encountered in the drill hole. Follow up work on the unexplained VEM anomaly and on the property was not reported.

Ontario Geological Survey 1980

In 1980 the Ontario Geological Survey (O.G.S.) published a preliminary map (P755) of Mann Township. The preliminary map was a compilation of past work on the property and geology of the Township. The past work included VEM anomalies and the drill hole location of work completed by Holmer Gold Mines.

Ontario Geological Survey 1988

In 1988 the O.G.S. completed an airborne geophysical survey over the Timmins area, which included Mann and Duff Townships. The survey delineated the Mann Complex as a strong positive magnetic feature that extends for approximately 40 km of strike length . A number of EM anomalies were identified on the Mann Project claims.

Leonard Hill (1990)

In 1990, Leonard Hill staked the Mann Project claims and over the next eight years prospected and completed a total of seven diamond drill holes (788 m total drilling), on the property. The diamond drilling was located along several locations along the Frederick House River. The purpose of the drilling was to evaluate the platinum group element and diamond potential of the property. Mr. Hill reported intersecting a single diamond in drill core, and has panned several diamonds from the river. A total of eighteen samples were assayed for Ni, Cu, Au and PGE mineralization. One core sample returned 522 ppb PGE and AU over 0.91 m. Sampling was not completed above or below this sample.

Dave Good (1994)

In 1994, during a period of time while Leonard Hill was actively working on the Mann Project, D. Good completed a research program on the Mann Complex, which included detailed mapping and sampling of outcrop on the Mann Project. In addition drill core from one of the Leonard Hill drill holes (91 – 1) was studied and sampled. Assay results from outcrop

and drill core returned highly anomalous PGE and gold results. Assay results from this work are included in Table 4, with channel sample locations on Figure 5.

Leonard Hill OPAP (1998 – 1999)

In 1998 Len Hill applied for and received an OPAP grant ($10,000), from the Ontario Ministry of Northern Development and Mines. A total of 10.225 km of linecutting was completed at 100 metre spaced lines with picket stations established every 25 metres. Prospecting and mapping was completed however proved to be of limited effectiveness with outcrop exposure of<1%. The best exposure of bedrock is situated along the Frederick House River at the bridge crossing. The continuous outcrop exposure consists of peridotite, dunite, pryroxenite and gabbro.

A total 9.225 km of HLEM surveys were completed, with 100m length cable and 25m spaced stations. The survey was intended to locate a number of airborne EM anomalies. The HLEM survey identified a significant EM anomaly on the central portion of the grid from L 15+00E / 13 +00N to L 19 +00E / 11 + 75N. The EM anomaly is located coincident with a strong airborne EM anomaly.

A total of 10.225 km of magnetometer surveys were completed, with readings taken at 25 m spaced stations. The survey identified a significant magnetic high horizon, coincident with the HLEM anomaly. Adjacent to mag high feature is a strong magnetic low, which extends for approximately 300 m. A soil survey was planned but due to the extensive clay cover was not completed.

Leonard Hill OPAP (1999-2000)

In 1999 Leonard Hill applied for and received an OPAP grant ($15,000), from the Ontario Ministry of Northern Development and Mines. Work was extended to the portion of the property not covered by the 1998-1999 OPAP program. A total of 9 km of linecutting was completed at 100 m spaced lines with picket stations established every 25 m. A total 6.275 km of HLEM surveys (177 Hz, 444 Hz) were completed, with a 100 m length cable and 25 m spaced stations. The survey was intended to locate a number of airborne EM anomalies. The HLEM survey identified a significant EM anomaly at L 10+00E / 6+25 N extending to L 6+00 E / 9+25 N. The EM anomaly is located along the flank of a moderate to strong magnetic feature. Several weaker single line anomalies were also identified.

A total of 8.15 km of magnetometer surveys were completed, with readings taken at 25 m spaced stations. The survey identified a significant magnetic high horizon, extending from L 6+00 E through to L 13+00 E in the northern portion of the grid.

A single line IP survey was completed on the southern portion of L 17+00 E, to cover a HLEM/Mag anomaly identified in the 1998 – 1999 OPAP program. The survey identified two zones of chargeability proximal to the axis of an HLEM anomaly. The first anomaly is centered at L 17+00 E / 12+50 N and consists of a moderate chargeability. The second anomaly is centered at L 17+00 E /11+25 N, and consists of a strong chargeability with low resistivity. Interpretation suggests this anomaly is a conductive horizon.

A single diamond drill hole MAN-01 (200.25 m) was completed to test the two chargeability zones identified in the IP survey. Massive cumulate textured peridotite, with two narrow sections of leucogabbro was intersected. Although zones of heavy sulphides were not encountered, fine disseminated sulphides were encountered throughout the hole. Re-interpretation of the geophysics in conjunction with the drilling indicates that the dip may be near vertical, and that the hole did not reach the geophysical target. The hole was not completed due to lack of funds. A log of MAN-01 is included in Appendix B.

March to May 2001 Geological and Geophysical Programs

A program of geological mapping along the Frederick House River(Fig 5) and relogging and sampling of nine historic diamond drill holes(Appendix B) was carried out by T. Keast between March and May 2001. In conjunction with this work, geophysical surveys were carried out by Geoserve Canada under the direction of R.J. Daigle(See accompanying report). 14.8 km of lines were cut at 100 metre intervals and chained and picketed at 25 metre intervals. A total field magnetic survey was carried out over these lines. This survey was compiled with previous

between March and May 2001. In conjunction with this work, geophysical surveys were carried out by Geoserve Canada under the direction of R.J. Daigle(See accompanying report). 14.8 km of lines were cut at 100 metre intervals and chained and picketed at 25 metre intervals. A total field magnetic survey was carried out over these lines. This survey was compiled with previous surveys to produce a map showing ground magnetic coverage for the whole property. A Time Domain IP was completed over 7.5 km. in the central part of the property.

The geological and geophysical programs defined targets of possible PGM enrichment in two main areas of the property. The original showing immediately north of the west end of the bridge across the Frederick House River was mapped in better detail. This area is a magnetic low, possibly due to hydrothermal activity causing destruction of magnetite. Another area of magnetic lows with coincident IP chargeability highs was outlined on lines 1300 and 1400 East immediately west of the Frederick House River. These anomalies could be the result of hydrothermal activity and sulphide emplacement.

Conclusions

The Mann Project, which consists of 19 claims covering 304 ha, is situated within Mann Township and Duff Township of the Porcupine Mining Division.The claims are situated within the Mann intrusive complex, a large, layered ultramafic intrusion, which extends for 40 km of strike length with a width greater than 1.5 km. Recent studies of the complex have indicated a chemistry similar to that of the ultramafic rocks which host the Alexo Ni-Cu sulphide deposit. In addition these same studies have identified significant anomalous PGE over considerable widths in outcrop channel samples and in diamond drill core. This PGE mineralization represents a new exploration target for the complex. An interesting feature of the Mann Complex, in particular the Mann Project, is the PGE are concentrated in a clinopyroxenite unit and are distinguished by only trace sulphides. The clinopyroxene unit is a medium grained adcumulate, between 14 – 30 m thick and >500 m in length. Mineralization is characterized by: a) Pt+ Pd up to 1.1 gm/t with local high Pt/Pd ratios, b) low sulphide content (<0.1% wt.% S), c) low Ni, Cu and Co, and d) PGE minerals intimately associated with chlorite+secondary clinopyroxenite+-spinel alteration of hydrothermal origin. According to Good (1999), "the close association of hydrothermal clinopyroxene, chlorite, and sulphides plus platinum-group minerals implies a hydrothermal origin for the PGE mineralization. The apparent controls on the transport and deposition of PGE are similar to those of other PGE deposits of hydrothermal origin, such as the platiniferous pipes of the Bushveld Complex."

Recommendations

A diamond drilling program of at least 1000metres is recommended to test existing known targets from past geophysical surveys, extend DDH MAN-01 an additional 75 m, and test targets identified by the work reported on here. This program is estimated to cost $85,000 and take 16 days to complete.

Respectfully Submitted,

Author's Statement of Qualifications

Statement of Qualifications

I, David St. Clair Dunn, Professional Geoscientist, with a business address at 1154 Marine Drive, Gibsons, B.C., Canada certify that:

1. I am a graduate of the University of British Columbia with a degree of Bachelor of Science in Geology.

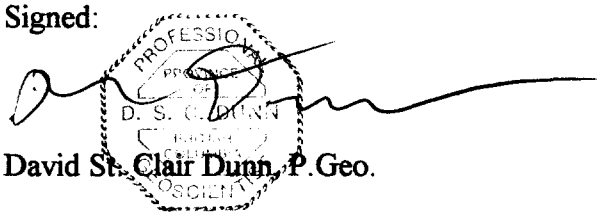
2. I am registered as a Professional Geoscientist with the British Columbia Association of Professional Engineers and Geoscientists (Reg. # 18,479).

3. I have practiced my profession for 21 years.

4. I have based my conclusions and recommendations in this report on a review of all available reports and supervision of the March to May 2001 geological and geophysical programs.

5. I am Vice President-Exploration and a Director of Tres-Or Resources Ltd. and hold stock and options to purchase stock in that company.

Signed:



David St. Clair Dunn, P.Geo. November 15, 2001

TABLES

APPENDICES

SUMMARY

During May of 2000, the author was contracted by Tres-Or Resources Ltd. to prepare a Geological Report on the Mann Project. The Mann Project, which consists of 19 claims covering 304 hectares (ha), is situated within Mann Township and Duff Township of the Porcupine Mining Division. The claims are situated within the Mann intrusive complex a large ultramafic intrusion, which extends for 40 kilometres (km) of strike length with a width of greater than 1.5 km. Several nickel-copper (Ni-Cu) sulphide showings and platinum group element (PGE) showings have been identified within the complex. Recent studies of the complex have indicated a chemistry of the ultramafic rocks similar to that of the rocks which host the Alexo Ni-Cu sulphide deposit. In addition, these same studies have identified significant anomalous platinum group element (PGE) mineralization (>150 ppb PGE+Au) over considerable widths. The PGE mineralization includes rock-saw channel samples which returned up to 654 ppb combined PGE and Au over 12.20 metres (m), and one diamond drill hole which returned 238 ppb combined Au and PGE over a core length of 10.70 m.

A two-phase exploration program is recommended to evaluate the PGE and Ni-Cu sulphide potential of the Mann Project. The recommended exploration program includes line cutting, horizontal loop electromagnetic (HLEM) surveys, magnetometer (mag) surveys, geological mapping, and diamond drilling. The total estimated cost of the proposed exploration program is **$102,321**.

INTRODUCTION

During May of 2000, the author was contracted by Tres-Or Resources Ltd. (Tres-Or), to prepare a Geological Report on the Mann Project. The background work involved in preparing the report included a review of regional geological and geophysical surveys completed by government agencies, exploration activities by

previous operators, work on the property by the author over the past two years and examination of pertinent drill core.

The Mann Project consists of 19 contiguous mining claims covering 304 ha, situated within Duff Township and Mann Township, of the Porcupine Mining Division. The project is located 47 km north of Timmins Ontario, within the Mann ultramafic complex. The Mann ultramafic complex lies within the Kidd-Munro Assemblage and Stoughton Roquemaure Assemblage of the Abitibi subprovince. Previous exploration programs on the property have been directed towards identifying Ni-Cu sulphide mineralization. Work has included linecutting, HLEM surveys, mag surveys, limited Induced Polarization (IP) surveys, and minor diamond drilling. The Ontario Geological Survey (O.G.S.) completed preliminary mapping programs, and airborne EM and mag surveys.

Recent geological studies of the Mann intrusive complex as part of a larger Kidd Munro study have identified significant PGE mineralization on the Mann Project. PGE values in both channel samples and diamond drill core have returned highly anomalous (>150 ppb PGE+Au) assay results. The PGE mineralization is hosted within ultramafic rocks including clinopyroxenite and peridotite. The PGE mineralization is not associated with zones of heavy sulphide mineralization, as observed at other PGE showings and deposits. The apparent controls on the transport and deposition of PGE are similar to those of other PGE deposits of hydrothermal origin, such as the platiniferous pipes of the Bushveld Complex.

A second important result of the studies of the Mann intrusive complex was that the chemistry of the ultramfic rocks on the Mann Project were found to be similar to those which host the Alexo Ni-Cu sulphide deposit, located approximately 33 km to the southeast. A number of geophysical anomalies have been identified on the Mann Project, which represent Ni-Cu sulphide targets.

Additional work is recommended for the Mann Project. A two-phase exploration program is recommended to evaluate this new PGE mineralization. A proposed exploration budget of **$102,321** is recommended to evaluate the PGE and Ni-Cu sulphide potential of the property.

PROJECT LOCATION AND ACCESS

The Mann Project is located 47 km north of Timmins Ontario, within Duff Township and Mann Township, of the Porcupine Mining Division (**Figure 1**). The claims are situated in the northwest corner of Mann Township and the northeast corner of Duff Township. The project is centered at 48°52'N and 81°02' NTS 42 A/NW.

The Mann Project is easily accessed by travelling north along Hwy 11 approximately 14 km northwest of the Iroqouis Falls turnoff (Hwy 578), to the Potter Station turnoff. Travel west along this road for 19 km until you reach a bridge, which crosses the Frederick House River. This is the central portion of the Mann Project. A number of trails access the north and west portions of the property.

TOPOGRAPHY AND CLIMATE

The topography of the Mann Project is flat to gently rolling. Outcrop exposure is low, approximately 1-2%. The majority of the property is covered by spruce bog, thick alder and muskeg. Drainage is controlled by a number of small creeks, which generally drain to the northwest into the Frederick House River, which in turn drains north.

Figure 1: property Location

The climate of the project area is warm and dry in the summer months from May through to September, and cold and snowy from November to March. Temperatures range from +30 Celsius in the summer to –30 Celsius in the winter.

LAND TENURE AND OWNERSHIP

The Mann Project consists of 19 contiguous claims covering 304 ha, situated within Mann Township and Duff Township of the Porcupine Mining Division (**Figure 2**). Leonard Hill of South Porcupine, Ontario, is the registered holder (100%) of these claims. Tres-Or can earn a 100% interest in the property by making cash and stock payments with Leonard Hill retaining a royalty. A listing of claims is included in **Table 1**. Claim abstract summaries are included in **Appendix I**.

REGIONAL GEOLOGY

The exploration target sought for is platinum group element mineralization and nickel-copper sulphide mineralization, hosted within specific layers of the Mann ultramafic intrusion. Ni-Cu sulphide deposits are generally associated with ultramafic and gabbroic volcanic rocks of both intrusive and extrusive nature. The Ni-Cu sulphide deposits are generally associated within a specific sulphide rich horizon, which is generally conductive due to the high sulphide content. A summary of Ni-Cu sulphide deposits from the Timmins Area is included in **Table 2.**

Table 2 - Ni-Cu Sulphide Deposits of the Timmins Area

Deposit Name	**Grade**	**Tonnes**
Texmont	0.93% Ni, Cu N.A.	3,190,000
Langmuir (1&2)	2.09% Ni, 0.08% Cu	1,600,00
Alexo	4.5% Ni, 0.50% Cu	52,000
Redstone	2.39% Ni, 0.09% Cu	1,220,000
Montcalm	1.44% Ni, 0.68% Cu	3,560,000

The Mann Project is situated within the Mann intrusive complex of the Abitibi subprovince. It is located at the northwestern end of the belt of ultramafic/mafic intrusive and extrusive rocks included in the Stoughton-Roquemaure assemblage, as recognized by Jackson and Fyon (1991). The geology of Mann Township was mapped by Satterly (1959), and Hunt and Richard (1980), and included in the regional studies of Jensen and Langford (1985).

Figure 2

The Mann intrusive complex is very large, with a strike length greater than 40 km and a thickness greater than 1.5 km (**Figure 3**). The complex occurs approximately 28 km northeast of the Kidd Creek massive sulphide deposit, within the northwestern end of a belt of ultramafic/mafic intrusive and extrusive rocks included in the Kidd-Munro and Stoughton-Roquemaure assemblages. In addition to ultramafic and mafic intrusions, the major lithologies in the area are predominantly northwestly striking mafic metavolcanics accompanied by minor intermediate matavolcanics and interflow sediments (**Figure 4**). The Mann complex is folded along a west to northwest trending fold axis. The metamorthpic grade is mid-greenschist facies.

PROPERTY GEOLOGY

The property geology is based upon work by government agencies, work in the area by previous operators, and a research paper by Good, Crocket, and Barnet (1997). Regional mapping and limited diamond drilling on the project (nine holes) indicates the presence of the ultramafic intrusion. Diamond drilling to the north of the project area has intersected anomalous Ni-Cu mineralization in ultramafic flows, intrusions and sediments.

Details of the size and composition of the Mann intrusive complex are poorly understood due to limited outcrop and the structural complexity. Three major rock types have been documented on the Mann propoerty: peridotite, clinopyroxenite, and gabbro (**Figure 5**).

Peridoite

The peridotite is predominately wehrlite with minor serpentinite. The wehrlite is a hetradcumulate and consists of medium-grained subrounded olivine and interstital subophitic clinopyroxene (augite), subhedral chromite and minor

anhedral orthopyroxene. Serpentinite occurs locally and consists of >95% serpentine abd 1-5% fine grained magnetite.

Clinopyroxenite

Based upon limited outcrop exposure and one diamond drill hole intersection, the clinopyroxenite member in the mapped section is between 14 and 30 m thick with a strike length of 500 m, south-southeast. The clinopyroxenite is an adcumulate composed of >90% clinopyroxene (augite).

Gabbro

The gabbro unit is medium grained and consists of approximately equal portions of subhedral plagioclase and anhedral clinopyroxene, along with minor amounts of orthopyroxene, quartz, epidote and magnetite.

Research by Good, Crocket and Barnet on the central portion of the Mann Project concluded that "Clinopyroxenite in the mafic-ultramafic complex in Mann township apparently crystallized from magma similar to that which formed the sulphide bearing komattiite at the Ni-Cu Alexo Deposit". This research indicated that exploration potential exists for the development of Ni-Cu sulphide mineralization in the Mann Complex, specifically on the Mann Project. PGE mineralization identified on the Mann Project is hosted within ultramafic rocks including clinopyroxenite and peridotite. The PGE mineralization is not associated with zones of heavy sulphide mineralization, as observed at other PGE showings and deposits. The apparent controls on the transport and deposition of PGE are similar to those of other PGE deposits of hydrothermal origin, such as the platiniferous pipes of the Bushveld Complex.

PREVIOUS EXPLORATION

The Mann Project has received limited exploration for a variety of commodities

over the past twenty years. Past work on the property has included government mapping and airborne geophysical surveys. Assessment work filed by previous operators on the property is limited. A summary of previous work programs is included below.

Holmer Gold Mines (1973)

In 1973, Holmer Gold Mines completed vertical electromagnetic (VEM) surveys and completed one diamond drill hole to test one of the EM anomalies. The drill hole intersected peridotite, pyroxenite and ultramafic porphyry. A summary of the hole is included in **Table 3**. Mineralization to account for the VEM anomaly was not encountered in the drill hole. Follow up work on the unexplained VEM anomaly and on the property was not reported.

Table 3 – Holmer Gold Mines DDH 73-6

From – To (feet)	Rock Type
0 – 40 ft	Casing
40 – 368.5	Peridotite
368.5 – 379.5	Ultramafic Porphyry
379.5 – 393.5	Peridotite
393.5 – 420	Ultramafic pyroxenite
420 – 499	Ultramafic Porphyry
499 – 550 (E.O.H.)	Peridotite

Ontario Geological Survey 1980

In 1980 the Ontario Geological Survey (O.G.S.) published a preliminary map (P 755) of Mann Township. The preliminary map was a compilation of past work on the property and geology of the Township. The past work included VEM anomalies and the drill hole location of work completed by Holmer Gold Mines.

Ontario Geological Survey 1988

In 1988 the O.G.S. completed an airborne geophysical survey over the Timmins area, which included Mann and Duff Townships. The survey delineated the Mann

Complex as a strong positive magnetic feature that extends for approximately 40 km of strike length (**Figure 6**). A number of EM anomalies were identified on the Mann Project claims.

Leonard Hill (1990)

In 1990, Leonard Hill staked the Mann Project claims and over the next eight years prospected and completed a total of seven diamond drill holes (788 m total drilling), on the property. The diamond drilling was located along several locations along the Frederick House River. The purpose of the drilling was to evaluate the platinum group element and diamond potential of the property. Mr. Hill reported intersecting a single diamond in drill core, and has panned several diamonds from the river. A total of eighteen samples were assayed for Ni, Cu, Au and PGE mineralization. One core sample returned 522 ppb PGE and Au over 0.91 m. Sampling was not completed above or below this sample.

Dave Good (1994)

In 1994, during a period of time while Leonard Hill was actively working on the Mann Project, D. Good completed a research program on the Mann Complex, which included detailed mapping and sampling of outcrop on the Mann Project. In addition drill core from one of the Lenonard Hill drill holes (91-1) was studied and sampled. Assay results from outcrop and drill core returned highly anomalous PGE and gold results. Assay results from this work are included in **Table 4,** with channel sample locations on **Figure 5**.

Leonard Hill OPAP (1998-1999)

In 1998 Len Hill applied for and received an OPAP grant ($10,000), from the Ontario Ministry of Northern Development and Mines. A total of 10.225 km of linecutting was completed at 100 metre spaced lines with picket stations established every 25 metres. Prospecting and mapping was completed however proved to be of limited effectiveness with outcrop exposure of <1%. The best exposure of bedrock is situated along the Frederick House River at the bridge

crossing. The continuous outcrop exposure consists of peridotite, dunite, pyroxenite and gabbro.

A total 9.225 km of HLEM surveys were completed, with 100 m length cable and 25 m spaced stations. The survey was intended to locate a number of airborne EM anomalies. The HLEM survey identified a significant EM anomaly on the central portion of the grid from L 15+00 E / 13+00 N to L 19+00 E / 11+75 N. The EM anomaly is located coincident with a strong airborne EM anomaly.

A total of 10.225 km of magnetometer surveys were completed, with readings taken at 25 m spaced stations. The survey identified a significant magnetic high horizon, coincident with the HLEM anomaly. Adjacent to mag high feature is a strong magnetic low, which extends for approximately 300 m. A soil survey was planned but due to the extensive clay cover was not completed. Clays are not a good medium for soil surveys.

Leonard Hill OPAP (1999-2000)

In 1999 Leonard Hill applied for and received an OPAP grant ($15,000), from the Ontario Ministry of Northern Development and Mines. Work was extended to the portion of the property not covered by the 1998-1999 OPAP program. A total of 9 km of linecutting was completed at 100 m spaced lines with picket stations established every 25 m. A total 6.275 km of HLEM surveys (1777 Hz, 444 Hz) were completed, with a 100 m length cable and 25 m spaced stations. The survey was intended to locate a number of airborne EM anomalies. The HLEM survey identified a significant EM anomaly at L 10+00 E / 6+25 N extending to L 6+00 E / 9+25 N. The EM anomaly is located along the flank of a moderate to strong magnetic feature. Several weaker single line anomalies were also identified.

A total of 8.15 km of magnetometer surveys were completed, with readings taken at 25 m spaced stations. The survey identified a significant magnetic high

horizon, extending from L 6+00 E through to L 13+00 E in the northern portion of the grid.

A single line IP survey was completed on the southern portion of L 17+00 E, to cover a HLEM/Mag anomaly identified in the 1998-1999 OPAP program. The survey identified two zones of chargeability proximal to the axis of an HLEM anomaly. The first anomaly is centered at L 17+00 E / 12+50 N and consists of a moderate chargeability. The second anomaly is centered at L 17+00 E / 11+25 N, and consists of a strong chargeability with low resistivity. Interpretation suggests this anomaly is a conductive horizon. Results of the 1998 and 1999 OPAP geophysical programs are included in **Figure 7** and **Figure 8**.

A single diamond drill hole MAN-01 (200.25 m) was completed to test the two chargeability zones identified in the IP survey. Massive cumulate textured peridotite, with two narrow sections of leucogabbro was intersected. Although zones of heavy sulphides were not encountered, fine disseminated sulphides were encountered throughout the hole. Re-interpretation of the geophysics in conjunction with the drilling indicates that the dip may be near vertical, and that the hole did not reach the geophysical target. The hole was not completed due to lack of funds. A summary of MAN-01 is included in **Table 5**.

Table 5 – MAN-01 Summary

From – To (metres)	Rock Type

CONCLUSIONS AND RECOMMENDATIONS

The Mann Project, which consists of 19 claims covering 304 ha, is situated within Mann Township and Duff Township of the Porcupine Mining Division. The claims are situated within the Mann intrusive complex, a large ultramafic intrusion, which extends for 40 km of strike length with a width greater than 1.5 km. Recent studies of the complex have indicated a chemistry similar to that of ultramafic rocks which host the Alexo Ni-Cu sulphide deposit. In addition these same studies have identified significant anomalous PGE over considerable widths in outcrop channel samples and in diamond drill core. This PGE mineralization represents a new exploration target for the complex. An interesting feature of the Mann Complex, in particular the Mann Project, is the PGE are concentrated in a clinopyroxenite unit and are distinguished by only trace sulphides. The clinopyroxene unit is a medium grained adcumulate, between 14-30 m thick and >500 m in length. Mineralization is characterized by: a) Pt+Pd up to 1.1 gm/t with local high Pt/Pd ratios, b) low sulphide content (<0.1% wt.% S), c) low Ni, Cu and Co, and d) PGE minerals intimately associated with chlorite+secondary clinopyroxenite+-spinel alteration of hydrothermal origin. According to Good (1999), "the close spatial association of hydrothermal clinopyroxene ,chlorite, and sulphides plus platinum-group minerals implies a hydrothermal origin for the PGE mineralization. The apparent controls on the transport and deposition of PGE are similar to those of other PGE deposits of hydrothermal origin, such as the platiniferous pipes of the Bushveld Complex."

A two-phase exploration program is recommended to evaluate the Ni-Cu sulphide and PGE potential of the Mann Project. The total estimated cost of the proposed exploration program **$102,321 (Table 6)**.

Phase I of the proposed program includes linecutting, geophysical surveys, geological mapping, core re-logging and assaying of the existing Leonard Hill drill core. This work will help increase the understanding of the PGE

Table 6 - Mann Project Proposed Budget

			Total
Phase I	***Linecutting***

mineralization, identify and define the prospective horizon, and follow up on PGE mineralization identified in one core sample (DDH 96-1, 522 ppb PGE and Au over 0.91 m). Sampling was not completed above or below this anomalous result. The total cost of the *Phase I* program is **$26,278**.

Phase II of the proposed program is contingent upon the results of the *Phase I* program. *Phase II* will focus on diamond drill testing (1,000 m) existing known targets from pst geophysical surveys, extending DDH MAN-01 an additional 75 m, and testing targets identified in the *Phase I* program. The total cost of the *Phase II* program is estimated at **$76,044**.

CERTIFICATE OF QUALIFICATIONS

I, **Todd Keast**, of 1204 Grace Ave., Porcupine, Ontario, do hereby certify that:

1. I am the author of this report.

2. I am a graduate of the University of Manitoba, Winnipeg, Manitoba, having received an Honors Bachelor of Science (Geology), in 1986.

3. I have practiced in the field of mineral exploration since 1987, for a number of exploration companies throughout Manitoba, Ontario, and Quebec.

4. I am a Fellow of the Geological Association of Canada.

5. I am a member of the Canadian Institute of Mining and Metallurgy.

6. I am a Professional Geoscientist registered with the Association of Professional Engineers and Geoscientists of the Province of British Columbia.

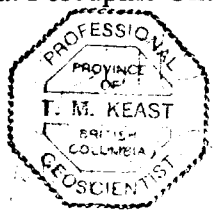
7. I am a Professional Geologist registered with the Association of Professional Engineers and Geologists and Geophysicists of Alberta.

8. I have not received nor do I expect to receive any interest in the Mann Project nor in any projects within ten kilometers of the Mann Project.

9. I do not own nor do I expect to receive, directly or indirectly, any securities in Tres–Or Resources Ltd.

10. I consent to the use of this report by Tres-Or Resources Ltd..

Dated at Porcupine Ontario, May 3, 2000.



Todd Keast, P.Geo.

Submission Number: 2.23925
Transaction Number(s): W0260.01191

Dear Sir or Madam

Subject: Approval of Assessment Work

We have approved your Assessment Work Submission with the above noted Transaction Number(s). The attached Work Report Summary indicates the results of the approval.

At the discretion of the Ministry, the assessment work performed on the mining lands noted in this work report may be subject to inspection and/or investigation at any time.

The value of work for this submission has been reduced to $7600.00 to reflect the information contained in the report and maps.

If you have any question regarding this correspondence, please contact LUCILLE JEROME by email at lucille.jerome@ndm.gov.on.ca or by phone at (705) 670-5858.

Yours Sincerely,

Ron Gashinski
Senior Manager, Mining Lands Section
