1.0 EXECUTIVE SUMMARY

An extensive enzyme leach soil geochemical sampling program was executed in the summer and fall of 1996 on the Mann Belt project on grids AUR95-02, CAL95-01, DUF95-02, and DUF96-03.

Enzyme leach geochemical surveys were used as a tool to complement ground geophysical surveys in the Mann Belt Projects area. The area is characterized by a lack of outcrop, numerous untested AEM anomalies, and known presence of graphitic argillites. The enzyme leach surveys were used to evaluate and prioritize targets on grids with untested conductors and untested conductors with nearby graphitic argillite.

The following conclusions were made based on the survey results:

- The survey did not produce false anomalies over barren graphite.
- The survey has helped to evaluate grids with known graphite horizons.
- Precise type of anomaly (apical vs. rabbit ears) is still not fully understood over VMS deposits hidden under moderately thick glacial overburden.

No further work is recommended on these grids at this time.

2.0 INTRODUCTION

From July to December 1996 an enzyme leach soil geochemical sampling program was carried out on the Mann Belt grids in order to locate and define base metal targets. Soil samples were analysed for trace elements, after being treated by the enzyme leach partial extraction technique (Clark, 1992), by ICP/MS at Activation Labs Ltd (Actlabs). Results are then used to define geochemical anomalies in overburden interpreted to be related to underlying mineralized bedrock.

3.0 LOCATION AND ACCESS

The grids are located in Aurora, Calvert, and Duff townships and are centered approximately 25 km northwest of the town of Iroquois Falls (Figure 1). A variety of concession and logging roads allow truck or ATV access to the all of the grids from Highways 11 and 655.

4.0 TOPOGRAPHY AND VEGETATION

The Mann Belt is bound by three rivers; to the east by the Abitibi river, to the west by the Buskegau River, and through the center by the Frederick House river with several creeks and streams crosscutting. Several good fishing lakes containing predominantly pike, perch, walleye and some rainbow trout also lie within the bounds of the property.

The area is generally flat and swampy with vegetation consisting of mostly black spruce and alders. The higher elevated areas are mostly covered by large poplar and birch, with some jackpine found generally associated with eskers. The area has been extensively logged in the past, mostly for black spruce and poplar, leaving behind a network of good logging roads for excellent access.

5.0 PREVIOUS GEOLOGICAL WORK

The 1988 OGS sponsored GEOTEM survey covers the bulk of the property area and detected numerous untested bedrock conductors. Compilation at 1:20,000 scale indicated the presence of a large ultramafic-mafic complex intercalated and mantled by mafic to felsic calc-alkaline and tholeiitic volcanic rocks and sedimentary units (chemical and clastic). Past exploration efforts also indicated the presence of a significant base metal showing in Mann Township.

6.0 1996 SOIL SAMPLING PROGRAM

6.1 INTRODUCTION

The enzyme leach soil geochemical surveys were used on the Mann Belt grids in an attempt to test geophysical targets and to evaluate the potential for base metal massive sulphide mineralization. Previous drilling of geophysical targets on the properties intersected graphitic argillites with minor sulphide mineralization. Large properties such as this one with many geophysical targets become very expensive to test properly. Enzyme leach soil geochemical sampling may be a cost effective tool to check geophysical targets and to test their base metal content.

6.2 ENZYME LEACH THEORY (from De Schutter, 1996)

Theory behind the enzyme leach analytical technique is discussed in great detail by Clark (1992) and references therein, and is included in this report in Appendix I. A brief summary of the technique is given below.

Conventional geochemical analyses of transported or deeply weathered overburden would reveal only the composition of overburden and not give any indication of underlying (and possibly mineralized) bedrock. Trace elements released by weathering of mineral deposits in bedrock will ascend through overburden via ground water flow, capillary action, or diffusion of volatile compounds. Amorphous manganese dioxide (MnO_2), which is usually a small proportion of the total MnO_2 component of the soil, is an effective trap for these upward migrating trace elements. A selective leach has been developed that employs a self-limiting enzyme reaction to selectively dissolve amorphous manganese dioxide and release trapped trace elements.

Three types of geochemical anomalies are generally found with the enzyme leach technique: 1) mechanical/hydromorphic dispersion anomalies are formed in basal till as mineralized bedrock is smeared down ice during glaciation; 2) oxidation halo anomalies are produced by the gradual oxidation of buried reduced bodies (massive sulphide) and are distinguished by an asymmetrical halo or partial halo formed around the reduced body by the "oxidation suite" and 3) apical anomalies are formed by diffusion of trace elements away from a concentrated source and develop directly over the source.

Studies indicate amorphous MnO_2 concentrates predominantly in B-horizon soils and as a consequence, care should be taken to sample from a consistent soil horizon rather than a constant depth. In general, the best level to sample appears to be between 20 and 40 cm depth below the "A" horizon.

Since amorphous MnO_2 makes up a minute proportion of the total MnO_2 in a sample, results of trace elements released by the enzyme leach are reported in parts-per-billion (ppb). An anomaly along a traverse line for a given element is tentatively identified when there is a noticeable trend below or above background

levels; this makes acquiring background samples very important. Significant anomalies are generally an order of magnitude (10X) above or below background levels.

The enzyme leach analytical package consists of 62 trace elements (Li, Be, Cl, Sc, Ti, V, Mn, Co, Ni, Cu, Zn, Ga, Ge, As, Se, Br, Rb, Sr, Y, Zr, Nb, Mo, Ru, Rh, Pd, Ag, Cd, In, Sn, Sb, Te, I, Cs, Ba, La, Ce, Pr, Nd, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb, Lu, Hf, Ta, W, Re, Os, Ir, Pt, Au, Hg, Tl, Pb, Bi, Th, and U) all of which are reported in parts-per-billion (ppb). Activation Laboratories Ltd. of Ancaster, Ontario performed the analyses. Hard copy results were first acquired by FAX and a diskette containing digital results usually followed a week later.

Samples consisted of 300 to 600 grams of material depending on grain size of the soil. All samples were air dried in a dry, cool room for a minimum of three days prior to shipping to Actlabs. Samples must be air dried as heating to above 40°C spoils the sample for a proper analysis (drives off the volatile components). All sample preparation was done by Actlabs; this included breaking-up samples with a hammer and sieving to minus 60 mesh. The leach solutions were then analysed for trace element concentrations (in ppb) by ICP/MS.

6.3 SOIL SAMPLING PROCEDURE (from De Schutter, 1996)

A total of 1889 B-horizon soil samples were collected from 88.5 km of traverse lines distributed over 18 grids, covering untested conductors, untested conductors with known graphitic argillites or drill intersected mineralization on specific horizons.

The sample material most commonly analyzed with the enzyme leach is B-horizon soils. Typical soil profiles found in humid climate areas consist of: an A horizon - an upper humus layer which is characterized by a dark layer of mixed organic and mineral matter which may or may not have a bleached mineral layer at the bottom; and a B-horizon - the top of which lacks organic material and where oxide coatings on mineral grains impart a brown to rusty red colour to the soil.

In the case of this study, the B-horizon samples consisted of clay to silty-clay or reddish brown fine grained sand. The typical soil profile encountered during this project consisted of :

1. a humus layer consisting of either grasses, leaf litter, lichen or muskeg ranging from 0.1 to 15 cm in thickness;
2. an A-horizon: a black, organic-rich layer (coarse mud) of 0.1 to > 50 cm in thickness with highly variable moisture content ranging from "soupy" to relatively dry. Thickness of this layer depends on topography and surface vegetation; spruce swamps have the thickest A-horizon while poplar forest in topographic highs have the thinnest A-horizon;
3. a "leached" zone (A2 horizon): an often chalky-white to black, coarse, organic-bearing layer underlying the A-horizon ranging from 0.5 to 5 cm in thickness. In well drained areas, this layer is generally light in colour (white to tan), dry and crumbly whereas in poorly drained areas it is usually very fine grained (clay to silt sized), very dense and very dark in colour (dark brown to black);
4. a B-horizon: an organic-free (may contain few hair-like root filaments), light coloured, clay to silty-clay layer or brown to reddish-brown, fine grained sand of undetermined thickness (usually greater than the reach of the auger). In well drained areas, the clay is generally dry and some shade of tan to brown (it may also have a grey-blue to grey-green tinge). In poorly drained areas, it is generally very dense and sticky and may range from a light tan to brown or grey-blue to grey-green in colour.

Samples were collected using a standard 135 cm long auger (including a 30 cm long sampling tube attached to the bottom). As a standard practice and where possible, the first 10-15 cm of the clay layer was thrown away to ensure the sample was free of organic and leached material. Generally, it required three to four passes with the auger down the same hole to acquire sufficient material to fill up the sample bag (300 to

500 grams). If the B-horizon was not reached after the first pass with the auger (30-35 cm depth), the sampling tube was cleaned of all material (humus and A-horizon material) by hand and reinserted down the hole until the proper material was reached.

In the more poorly drained areas, samples tended to be covered with a film of organic-rich mud because the sample tube was pulled back up through the A-horizon during extraction. Every effort was made to clean this film off all samples even though it was generally a very messy and time consuming task.

Soil sample books were used to note the location of samples (grid co-ordinates) and all pertinent information such as slope attitude, colour and composition of sample (clay, silt, sand,...), quality of drainage, vegetation and any extra remarks. Each sample site was marked with flagging tape upon which the sample number was written; the flagging tape was usually tied to the grid picket or to a nearby tree branch.

7.0 DATA MANIPULATION

Raw geochemical results were received on diskette as WK1 and CSV files. The data was then formatted in Excel for export into Geosoft™ in which the geochemical profiles were produced. The profiles were drawn at an appropriate scale and then exported as a DXF file into AUTOCAD where the profiles could be superimposed onto existing geological maps and/or profiles.

8.0 1996 ENZYME LEACH RESULTS

Enzyme leach geochemical profile plots (plan view maps, Appendix I) are found in the back of this report. The maps are drawn to an appropriate scale and include topography. It is important to pay close attention to the vertical scale of the geochemical profiles as it does vary from element to element (e.g. 1 cm = 20 ppb Br and 1 cm = 225 ppb Zn). The base line value is 0 for all profiles.

Appendix III includes all the raw geochemical data. All trace element values are reported in parts-per-billion (ppb); negative values indicate that the element is not detected at that lower limit (i.e. -10 ppb = below 10 ppb); S.Q. indicates that element is determined semi-quantitatively; and values = 999999 are greater than the working range of the instrument.

9.0 DISCUSSION and CONCLUSIONS

AUR95-02

The grid was sampled on July 8, 1996, by temporary summer staff Geoff Band, Jack Giroux, Joel Conquer, Andrew Reid, Jimmy Sevigny and Jamie Keenan. Samples were collected every 40 metres over 7 grid lines for a total of 90 samples over 3.6 line kilometres. The "B" horizon encountered on this grid was grey or brown clay at an average depth of 220 cm. The survey results show much higher background numbers to the north of the grid than the south. This is probably as a result of an overburden depth change or a lithology change.

CAL95-01

This grid was sampled on July 12, 1996, by Jimmy Sevigny and Jamie Keenan. Sample were collected every 40 metres over 3 grid lines for a total of 53 samples over 2.65 line kilometres. The "B" horizon encountered on this grid was reddish-brown sand at an average depth of 20 cm. This grid has not been drilled. The survey results show a slightly elevated trend cutting through the property. These elevated numbers are likely due to a small fault zone or jointing. The results also show no copper being detected throughout the property. As a result three additional samples were taken on September 15, 1996, on three

previously sampled sites. The results are listed below and show, in some elements, a huge difference in value. The reason for the difference is unknown. No anomalies were detected.

DUF95-02

This grid was sampled at first on lines 400W to 700W on September 25 and 27, 1996, by André Taillefer and Geoff Band. The remaining grid lines were sampled on November 22 to 25, 1996, by contractor Ron Leduc. Samples were collected every 50 metres over 9 grid lines for a total of 147 samples. The "B" horizon encountered on this grid was grey or brown clay at an average depth of 150 cm. This grid has been and intersected 28 metres of graphitic argillite with trace zinc and copper mineralization. The survey did not pick up any new mineralized zones.

DUF96-03

This grid was sampled at first on lines 400E, 600E and 800E on September 2nd, 1996, by Martin Stewart and Geoff Band. The remaining grid lines were sampled on November 13 to 22, 1996, by contractor Ron Leduc. Samples were collected every 50 metres over 15 grid lines for a total of 226 samples over 11.3 line kilometres. Sampling was hampered by deep overburden and the presence of 3 lakes and its tributaries. The "B" horizon encountered on this grid varied from grey sand on line 800E, to a combination of brown sand-clay on lines 400E and 600E, to grey silty clay for the remaining grid. The average depth of the "B" horizon varied dramatically also, from an average of 20 cm to the east of the grid, to an average of 150 cm to the west. This grid has been drilled and intersected a thick package of strongly foliated and faulted argillites and graphitic argillite with trace zinc and copper mineralization. The survey results show a slightly elevated trend on the northeast corner of the property. These elevated numbers are likely due to a small fault zone or jointing. The survey also shows a difference in background numbers from one sampling session to the other. This could be explained by the different soil types encountered during sampling. No other significant zones were found.

PRESIDENT'S MESSAGE

A Need for Volunteers

The Association of Exploration Geochemists was founded twenty-two years ago after members recognized the need for a professional organization to represent exploration geochemists. Our organization has been served over this period of time by a capable group of volunteers in the Executive, Council, EXPLORE, Journal of Geochemical Exploration (JGE), and various committees.

The AEG has reaffirmed its focus on exploration geochemistry but has also made the commitment to expand its contacts with professionals in related fields (e.g. environmental geochemistry) and to conduct activities which will serve the membership (e.g. education, professional registration, short courses, special publications). This taxes the limited time of existing volunteers.

As with any volunteer organization, there is a small active group of volunteers who carry out the vast majority of activities of the Association within the framework of several committees. In order to maintain the vitality of the organization, we need more members to participate in the endeavors of these committees.

The list of committees is included at the end of this column. The titles are, for the most part, self-explanatory and reflect the commitments and activities of the Association. The committees are of two types, those which were formed to address specific issues, such as the Bylaws Review, Elsevier Negotiations, and Membership Application forms. These committees are dissolved after their task has been accomplished. However, the vast majority of committees are ongoing. These committees need your input.

In the past, it has been difficult to determine who to contact to volunteer your assistance. For that reason, we are also including the corresponding addresses of the Committee Chairman. Contact the chairmen and volunteer your time to the Association.

A second way to participate is for members to upgrade their membership status to Voting Member. This gives you the opportunity to vote on matters concerning the Association and have a say in the direction of the Association. Applications may be obtained through the Association offices in Vancouver.

If you have any questions, comments, or suggestions for the Association, feel free to contact any of the Chairman listed starting on the next page.

TECHNICAL NOTES

Detection of Bedrock-related Geochemical Anomalies at the Surface of Transported Overburden

Introduction

The chemistry performed before instrumental determinations are made is critical to the quality of the geochemical interpretations made from the resulting data. In the 1970's and 1980's much emphasis in exploration geochemistry was placed on new instrumental techniques. Many geochemists found that volumes of multi-element data could be generated by inductively-coupled plasma/atomic emission spectroscopy (ICP/AES) for a relatively low cost. Consequently, interest in data handling and manipulation using computers to assist in producing interpretations increased dramatically. During this period of "Black Box" analyses the importance of preparatory chemistry was largely ignored, and the usefulness of analytical chemistry for unraveling dispersion processes was frequently overlooked. Consequently, geochemical exploration data often have been interpreted with little regard for the strengths or weaknesses of the analytical techniques used to produce the data. Also, an adage that has often been quoted is that you can not do exploration geochemistry on transported overburden, because the material in the overburden is unrelated to the bedrock that it covers. This viewpoint exemplifies a lack of comprehension of chemical mobility, geochemical barriers, and how selective partial analysis can be used to enhance extremely subtle geochemical anomalies.

CONTENTS

LINDGREN AWARD NOMINATIONS

The Lindgren award is offered annually by the Society of Economic Geologists to a young geologist whose published research represents an outstanding contribution to economic geology. The award, which consists of a citation, dues-free membership in the Society, and travel to the fall meeting for the presentation, is not restricted as to the candidate's nationality, place of employment, or membership in the Society. The work for which the Lindgren Award is given must have been published as a single paper or series of papers in a recognized journal before the author's 35th birthday, and the awardee must be less than 37 years of age on January 1 of the year in which the award is presented.

The award can be given for contributions to economic geology from any subdiscipline of geology (including, among others, structural geology, mineralogy, petrology, geochemistry, stratigraphy, geophysics, and mine geology).

Any Society member in good standing may nominate candidates for the award. We are currently seeking nominations for the 1993 Award, for which nominees must have been born after January 1, 1956. Nominees who are not selected for 1993 but are still eligible will be considered for awards in following years. The deadline for nominations is October 30, 1992.

For more information please contact:

Technical Notes

Continued from Page 1

In the Canadian Shield, large areas are covered by one or more sequences of glacial till and glaciolacustrine sediments. In the Basin and Range Province much of the bedrock has been buried by basin fill. Typically the overburden in these regions is exotic to the bedrock that it covers. A conventional chemical analysis would reveal only the composition of the overburden and would not give any indication of the underlying bedrock. Drilling has been the only means of collecting useful geochemical samples in areas of extensive overburden. An inexpensive technique was needed for gathering meaningful geochemical data from overburden that would provide some indication of the chemistry of the bedrock.

Small amounts of trace elements mobilized by oxidation of sulfide minerals in the bedrock or basal till can migrate through overburden by various mechanisms, such as ground water flow, capillary action, or diffusion of volatile compounds. Oxides of manganese and iron, which form coatings on mineral grains in soils developed on overburden, are effective traps for mobilized elements. However, the proportion of a given element from a bedrock-related source that has been introduced into an overburden sample is typically very small compared to its total concentration in the overburden. Thus, it has been difficult to determine the amount of a trace element that has been added to the overburden rather than the total concentration. Selectively determining trace elements in oxide coatings can be an effective approach to mineral exploration in buried terrains. Chao (1984) thoroughly reviewed the principles and practices of partial analysis.

Analytical Problem

Amorphous manganese oxide, which is commonly a very small part of the total manganese oxides in soils, is one of the most efficient natural traps for trace elements mobilized in the surface/near-surface environment. The large surface area per unit mass and the random distribution of both positive and negative charges on the irregular surface of this material make it an ideal adsorber for a variety of cations, anions, and polar molecules. Anomalous concentrations of trace elements adsorbed by this material are often indicative of the chemistry of oxidizing minerals in the bedrock or basal till rather than the composition of the exotic overburden from which the soil formed. Previously, no partial leaches had been developed which were selective for amorphous manganese oxide.

Hydroxylamine hydrochloride has been used very effectively as a selective reducing agent for manganese oxide coatings (Canney and Nowlan, 1964; Chao, 1972). This reducing agent rapidly reacts with nearly all of the manganese oxide phases in a geological sample. It can be used along with other reagents in

Continued on Page 6

Technical Notes

Continued from Page 5

such dilute concentrations that any chemical attack upon the mineral substrates of the coatings is very minor. However, the concentrations of many trace elements in these leach solutions could be so low that specialized instrumental techniques would be needed to make determinations. These techniques would likely be inductively-coupled plasma/mass spectrometry (ICP/MS) and graphite furnace atomic absorption (GFAA). The presence of chloride ions in the hydroxylamine hydrochloride-leach solutions can produce extreme interferences for many elements by both of these instrumental techniques. Therefore, hydroxylamine hydrochloride is not a viable leaching agent when seeking many extremely low-level trace-element signatures.

Hydrogen peroxide also acts as a reducing agent for MnO_2. In an aqueous solution it will react with manganese dioxide, consuming hydrogen ions, and resulting in the manganese being reduced to the divalent state, which is soluble.

$$MnO_{2(s)} + H_2O_2 + 2H^+ \rightarrow Mn^{2+} + O_{2(aq)} + H_2O.$$

In this process, all the trace elements trapped in the manganese dioxide are released. Chao (1972) rejected the use of hydrogen peroxide as a selective leaching agent because, even at very high concentrations, it reacts very slowly with many crystalline phases of manganese dioxide (Taylor and McKenzie, 1966). However, even dilute concentrations of hydrogen peroxide vigorously react with amorphous manganese dioxide.

It would be possible to selectively leach for amorphous MnO_2 by adding H_2O_2 directly to the leach solution. However, the chemist would not know how much hydrogen peroxide should be used to leach each particular soil or sediment sample. If too much were added, there would be increased leaching of crystalline manganese oxides, as well as leaching of organic matter, sulfide minerals, and other oxidizable phases in the soil sample. Also, with some samples too high a concentration of H_2O_2 in the leach solution could produce precipitation of insoluble metal peroxides. Alternatively, if too little reagent were added, the leaching of amorphous manganese oxide would be incomplete.

Enzyme Leach

An enzyme chemical reaction slowly generates very low concentrations of hydrogen peroxide in aqueous media. Glucose oxidase reacts with dextrose (D-glucose) to produce hydrogen peroxide and gluconic acid.

$$\text{Dextrose} + O_{2(aq)} + H_2O \rightarrow^{\text{(Glucose Oxidase)}} \text{Gluconic Acid} + H_2O_2$$

Dilute hydrogen peroxide readily reduces and dissolves amorphous manganese dioxide, releasing trace elements and polar molecules trapped in that material. Gluconic acid complexes the metals and holds them in solution. Once all the amorphous manganese dioxide has been dissolved, the products of the glucose oxidase-dextrose reaction are no longer being consumed at a rapid rate, and the enzyme reaction virtually stops. The hydrogen peroxide concentration probably never exceeds 40 µg/ml, and sufficient gluconic acid is produced to complex the metals solubilized by the process. This self-limiting characteristic of the process minimizes undesirable leaching of mineral substrates. Thus, the background concentrations for many elements determined are extremely low and the anomaly/background contrast is often dramatically enhanced.

Trace-element concentrations for many elements in the leach solutions are often in the mid-to-low picogram-per-liter range. The only current instrumental technique that can be effectively used to determine such low concentrations for large numbers of elements in a significant number of samples is ICP/MS. Nothing is added to the leach solution that would be detrimental to the ICP/MS technique, or which would produce a serious analytical blank problem. The leach solutions are also amenable to determination of many trace elements by GFAA and ICP/AES.

Results and Discussion

In an early experiment with the Enzyme leach, a relatively large quantity of amorphous MnO_2 precipitate was dissolved in only one hour (Clark, pending). Alternatively, in a set of soil samples from a regional mineral-resource assessment project in northern Minnesota, the Enzyme leach typically leached less than five percent of the total manganese oxides in the samples (Clark pending; Clark, in press). Based on the observations of Taylor and McKenzie (1966), it was expected that very dilute hydrogen peroxide concentrations would have minimal leaching effect on many crystalline manganese oxide phases. Thus, it appears that the Enzyme leach is somewhat selective for amorphous manganese dioxide.

Crystalline manganese oxides are known to be effective traps for such metals as Ba, Co, Ni, and Zn. Enzyme leach analyses of soil samples often reveal anomalies not only of these metals, but also a long list of other trace elements, some of which occur as cations and others that form anions in the surficial environment. The list includes Ag, As, Bi, Br, Cd, Cl, Cu, Ga, I, In, Mo, Pb, Re, Sb, Se, Tl, U, V, and W. Because the surface chemistry of amorphous MnO_2 allows it to trap a variety of cations, anions, and polar molecules, selectively leaching for that material provides distinct advantages.

In samples that are identified as being part of a background population with respect to a number of leachable trace elements, a correlation is often observed among leachable Ba, Co, Mn, Ni, and Zn. However, in samples that have concentrations above threshold values for one or more elements, no relationship has been found between leachable Mn and the leachable

Continued on Page 8

Technical Notes

Continued from Page 6

concentrations of the anomalous elements. Therefore, the Enzyme leach is not prone to generating false anomalies.

Glacially Buried Terrain as in Desert Sediments.

A regional mineral-resource assessment project in the International Falls and Roseau 1°x2° quadrangle of Minnesota was the first large-scale application of the Enzyme leach. The bedrock in most of the region is buried by a minimum of two till sheets, and in most of the area these tills are capped by glaciolacustrine sediments from Glacial Lake Agassie. In the initial phase of that project, a pilot study revealed a relationship between Enzyme-leach anomalies in B-horizon soils and vegetation anomalies at the same sites. In effect, the B-horizon soils apparently have been acting as long-term integrators of vegetation anomalies (Clark, in press). Enzyme leaching of B-horizon soils proved to be the most cost-effective means of conducting a mineral-resource assessment of that region.

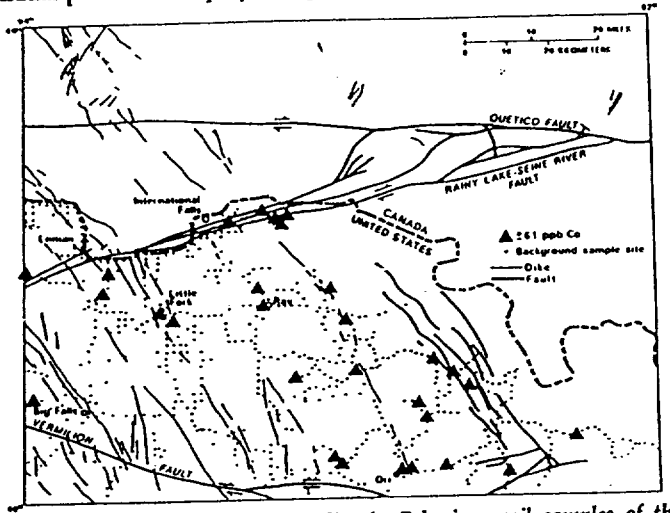

Fig. 1. Enzyme-leach Co anomalies in B-horizon soil samples of the International Fall 1°x2° quadrangle, Minnesota.

This geochemical study of northern Minnesota produced the first recognized evidence of potential for Proterozoic vein deposits in that region. A plot of cobalt anomalies in the International Falls 1°x2° quadrangle revealed an alignment of anomalous-sample sites along what appears to be northwest-striking structural trends (Fig. 1). Some of the trends coincided with diabase dikes, and the Co anomalies tended to occur within a short distance east or west of the termination of dike segments. Other trends appeared to be controlled by faults. Clark et al. (1990) observed that the diabase dikes could not be the sources of the Co, and plots of Ag and Tl revealed anomalous trends that either paralleled or coincided with the Co trends. The anomalous-sample sites tended to cluster in areas where structural trends evidently intersect in the covered basement. Stronger leaching methods did not perform as well as the Enzyme leach. An augmented version of the Enzyme leach (Clark et al. 1990) detected fewer anomalies. In a pilot study, the potassium iodide+ascorbic acid leach (Viets and others, 1984) and the oxalic acid leach (Alminas and Mosier, 1976; Church and others, 1987) failed to detect any of the anomalies along one of the trends southeast of International Falls.

Desert pediments. The first desert pediment study used soil samples collected along two traverses perpendicular to the mineralized structure that hosts the Sleeper ore body, in northwestern Nevada. A plot of Enzyme-leachable Re along traverse two (Fig. 2, 600 meters north of the pit) is one example of trace-element anomalies along that traverse. The overburden along traverse two (Fig. 2, 600 meters north of the pit) is one

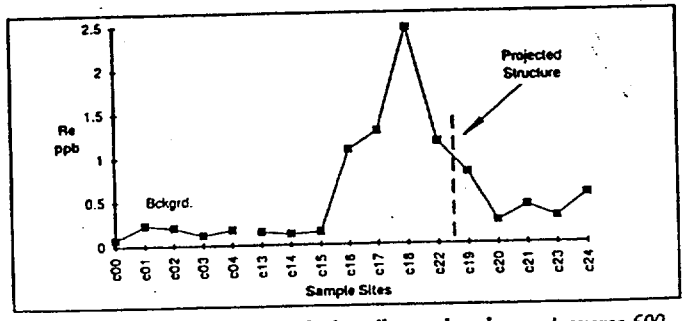

Fig. 2. Enzyme-leach Re anomaly in soil samples along a traverse 600 meters north of the Sleeper pit, Nevada. The vertical dashed line represents the approximate location of a buried mineralized structure. Sample site spacing along traverse 2 varies between 30 and 60 meters.

Technical Notes

Continued from Page 8

example of trace element anomalies along that traverse. The overburden along traverse 2 (sample sites c13-c24) consisted of from 20 meters to 40 meters of basin fill. The background-soil sample sites (c00-c04) were collected on basin fill up slope from the mineralized structure.

Anomaly/background ratios show the dramatic contrast of the Enzyme-leach soil anomalies found near the Sleeper mine (Fig. 3). The elements with the highest anomaly contrasts are those that characteristically occur as anions in the surficial environment. By comparison, the stronger partial leaching methods, potassium iodide+ascorbic acid (Viets and others, 1984) and oxalic acid (Alminas and Mosier, 1976; Church and others 1987), produced much lower anomaly contrasts than the Enzyme leach (Fig. 3). Even higher anomaly contrasts were obtained by using the Enzyme leach on soil samples

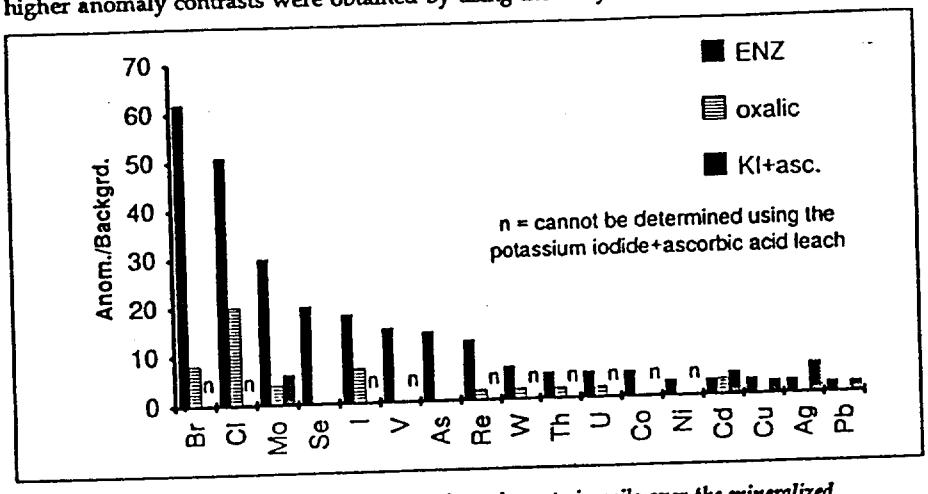

Fig. 3. Anomaly/background ratios for anomalous elements in soils over the mineralized structure at the Sleeper deposit, Nevada. The three analytical methods used were the Enzyme leach, the oxalic acid leach, and the potassium iodide + ascorbic acid leach.

collected over the Rabbit Creek deposit, in north central Nevada.

Enzyme leach analyses of soil samples from desert pediments at several localities have revealed strong correlations between anomalous concentrations of one or more halogens and other trace elements. The leachable concentrations of arsenic and iodine in the samples collected near the Sleeper mine show a nearly linear relationship (Fig. 4). Scatter plots of Mo and Cl and Re and Br also reveal similar relationships in the leach

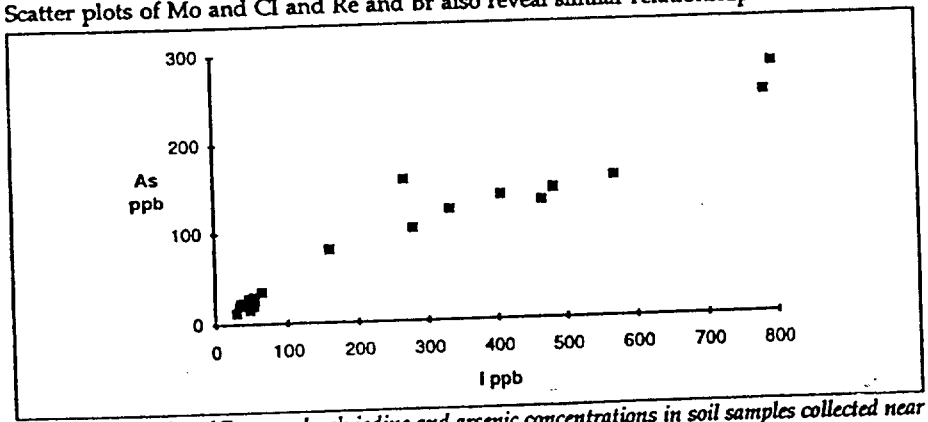

Fig. 4. Scatter plot of Enzyme-leach iodine and arsenic concentrations in soil samples collected near the Sleeper mine, Nevada.

data from the Sleeper samples. Figure 5 shows the nearly linear relationship between Sb and Br produced by Enzyme leaching of soils from another property in Nevada. The strong linear relationships between pairs of elements would seem to indicate that each pair is migrating together at that given location. Trace elements that correlate strongly with the halogens at various localities are those that tend to volatilize as halides under acid/oxidizing conditions used for chemical digestion of geological samples. Although the boiling points of halides and oxyhalides of these metals are 100°C to 300°C above

Continued on Page 10

Technical Notes

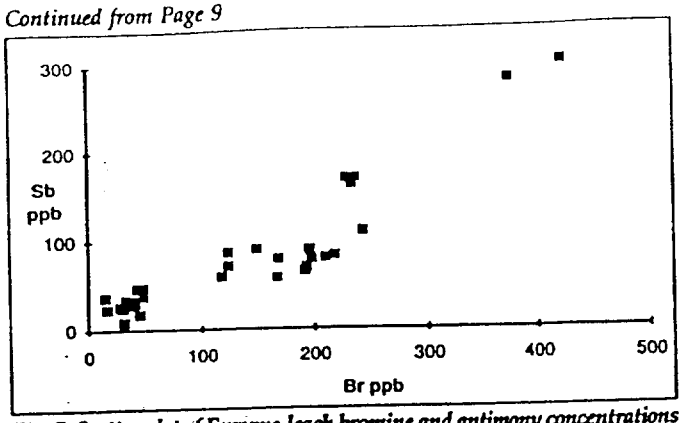

Fig. 5. Scatter plot of Enzyme-leach bromine and antimony concentrations in soil samples collected over a property in Nevada.

the ambient temperature, they would have moderate vapor pressure in localities where sulfide-rich bodies of rock were being oxidized. It seems that these halogen compounds are migrating very slowly through the overburden over extended periods of time and are being trapped by amorphous MnO_2 near the surface.

Limitations. The development of this new leaching technology does not diminish the need for performing pilot studies. In northern Minnesota it was essential to sample the B-horizon (Clark, in press). With desert soils, evidence suggests that the depth of collection can be of major importance. Where the overburden is generally less than 3 meters thick, stronger partial leaches usually produce greater anomaly contrasts. As an experiment, identical sample sets were sieved to minus 60 mesh in one case and pulverized in the other. The pulverized samples either failed to show any anomalies or the anomaly contrast was drastically reduced when compared to the sieved samples. Grinding may have caused this, because amorphous MnO_2 is a soft material that is readily reduced to a fine powder, which in turn may be dissipated by the air movement in and around the grinding apparatus. Alternatively, volatile compounds trapped in MnO_2 coatings could easily be lost due to the heat generated by the grinding process. Although the Enzyme leach performs extremely well for detecting currently active dispersal processes, in cases where barren oxide coatings have had time to accumulate on the surfaces of mineral grains, stronger leaching techniques produce more useful results.

Enzyme leaching of surficial geochemical samples is a relatively inexpensive technique that can be used to define overburden drilling targets. This new technology opens the door for cost-effective geochemical exploration for mineral deposits in many geographic areas where the bedrock is buried by overburden.

Sample Media

Applied geochemistry and, therefore, plans for geochemical mapping, are being driven increasingly by environmental considerations.

In 1991 it became clear from papers and discussions that the preferred sampling media for the IGM project are stream sediment, soil, and water, as and when analytical problems relating to low concentrations can be overcome. Support for overbank sampling seemed to weaken. Evidence presented by John Ridgway et al. in Uppsala seemed to confirm the opinions of others that for reliable interpretation they require, in general, more detailed site investigations than are practical for regional reconnaissance purposes.

The Uppsala Symposium on Environmental Geochemistry helped to clarify a number of issues. Water is becoming the most sought-after natural commodity and for obvious reasons attracts the greatest public interest. The Symposium underlined the need for baseline data on soils (sensu latu), as the almost-universal surface sampling media of general environmental significance. Stream sediments are complementary in providing enhanced sensitivity for some elements of economic importance, but this medium is of lesser interest to most scientists concerned with non-geological environmental questions. Lake sediments substitute for stream sediments in wet Shield areas with poorly developed drainage, and have the advantage that, with suitable sampling, long-term changes can be detected.

An important consideration in the selection of methods is that sample spacing for soil surveys, and to a lesser degree water, stream and lake sediment surveys, can be increased beyond that required for initial reconnaissance coverage to permit more detailed investigations for specific purposes. Since most countries have undertaken geochemical surveys and based their data on

GEOCHEMICAL MAPPING

Update on the International Geochemical Mapping Project

The International Geochemical Mapping (IGM) project, sponsored through UNESCO/IUGS as IGCP Project 259, distributes a newsletter in January each year to its 350 listed participants in 80 countries. The following is taken from the editorial in the latest edition, with updates from recent project meetings held in Keyworth U.K. April 22-24, and Reston, Virginia, May 8-10, 1992. For more background information about the project see Vol. 39 (1990) of the Journal of Geochemical Exploration.

Instructions: - For work performed on Crown Lands before recording a claim, use form 0240.
- Please type or print in ink.

2.17658

1. Recorded holder(s) (Attach a list if necessary)

Name	Client Number
FALCONBRIDGE LTD.	130679
Address	Telephone Number
P.O. BOX 1140, 571 MONETA AVE.	(705) 267-1188
TIMMINS, ONTARIO P4N 7H9	Fax Number (705) 264-6080
Name	Client Number
Address	Telephone Number
	Fax Number

2. Type of work performed: Check (✓) and report on only ONE of the following groups for this declaration.

☒ Geotechnical: prospecting, surveys, assays and work under section 18 (regs) ☐ Physical: drilling, stripping, trenching and associated assays ☐ Rehabilitation

Work Type	Office Use
GEOCHEMICAL SOIL SAMPLING	Commodity
	Total $ Value of Work Claimed $16,522
Dates Work Performed From 08 Day / 07 Month / 96 Year To 25 Day / 11 Month / 96 Year	NTS Reference
Global Positioning System Data (if available) — Township/Area: AURORA, CALVERT, DUFF	Mining Division: Porcupine
M or G-Plan Number	Resident Geologist District: Timmins

Please remember to: - obtain a work permit from the Ministry of Natural Resources as required;
- provide proper notice to surface rights holders before starting work;
- complete and attach a Statement of Costs, form 0212;
- provide a map showing contiguous mining lands that are linked for assigning work;
- include two copies of your technical report.

3. Person or companies who prepared the technical report (Attach a list if necessary)

RECEIVED SEP 19 1997 11:30 GEOSCIENCE ASSESSMENT OFFICE

RECEIVED SEP 18 1997 9:45 AM PORCUPINE MINING DIVISION

4. Certification by Recorded Holder or Agent

I, CHRISTINE PETCH (Print Name), do hereby certify that I have personal knowledge of the facts set forth in this Declaration of Assessment Work having caused the work to be performed or witnessed the same during or after its completion and, to the best of my knowledge, the annexed report is true.

Signature of Recorded Holder or Agent	Date
C. Petch	SEPT. 17, 1997
Agent's Address	Telephone Number / Fax Number
P.O. BOX 1140, 571 MONETA AVE, TIMMINS, ONT. P4N 7H9	(705) 267-1188 / (705) 264-6080

0241 (02/96)

Approved December 17/97.

5. **Work to be recorded and distributed.** Work can only be assigned to claims that are contiguous (adjoining) to the mining land where work was performed, at the time work was performed. A map showing the contiguous link must accompany this form.

	Mining Claim Number. Or if work was done on other eligible mining land, show in this column the location number indicated on the claim map.	Number of Claim Units. For other mining land, list hectares.	Value of work performed on this claim or other mining land.	Value of work applied to this claim.	Value of work assigned to other mining claims.	Bank. Value of work to be distributed at a future date.

I, CHRISTINE PETCH (Print Full Name), do hereby certify that the above work credits are eligible under subsection 7 (1) of the Assessment Work Regulation 6/96 for assignment to contiguous claims or for application to the claim where the work was done.

Signature of Recorded Holder or Agent (Authorized in Writing) C. Petch — Date SEPT. 17, 1997

6. **Instructions for cutting back credits that are not approved.**

Some of the credits claimed in this declaration may be cut back. Please check (✓) in the boxes below to show how you wish to prioritize the deletion of credits:

- ☐ 1. Credits are to be cut back from the Bank first, followed by option 2 or 3 or 4 as indicated.
- ☐ 2. Credits are to be cut back starting with the claims listed last, working backwards; or
- ☐ 3. Credits are to be cut back equally over all claims listed in this declaration; or
- ☒ 4. Credits are to be cut back as prioritized on the attached appendix or as follows (describe):

P1200983 (banked)

Note: If you have not indicated how your credits are to be deleted, credits will be cut back from the Bank first, followed by option number 2 if necessary.

Ontario Ministry of Northern Development and Mines

Statement of Costs for Assessment Credit

Transaction Number (office use): W9760.00350

Personal information collected on this form is obtained under the authority of subsection 6(1) of the Assessment Work Regulation 6/96. Under section 8 of the Mining Act, the information is a public record. This information will be used to review the assessment work and correspond with the mining land holder. Questions about this collection should be directed to the Chief Mining Recorder, Ministry of Northern Development and Mines, 6th Floor, 933 Ramsey Lake Road, Sudbury, Ontario, P3E 6B5.

2.17658

Work Type	Units of Work Depending on the type of work, list the number of hours/days worked, metres of drilling, kilometres of grid line, number of samples, etc.	Cost Per Unit of work	Total Cost
SOIL SAMPLING	28 PERSON DAYS WORKED	$100	2,800
LAB ANALYSES	516 SAMPLES	$22.50	11,610
Associated Costs (e.g. supplies, mobilization and demobilization).			
SAMPLE BAGS (516 ~~SAMPLES~~ SAMPLES)		0.41	212
Transportation Costs			
TRUCK RENTAL (1 MONTH)			500
Food and Lodging Costs			
FOOD ($800) + HOTEL ($600)			1,400
		Total Value of Assessment Work	16,522

RECEIVED
SEP 18 1997
PORCUPINE MINING DIVISION

Calculations of Filing Discounts:

1. Work filed within two years of performance is claimed at 100% of the above Total Value of Assessment Work.
2. If work is filed after two years and up to five years after performance, it can only be claimed at 50% of the Total Value of Assessment Work. If this situation applies to your claims, use the calculation below:

TOTAL VALUE OF ASSESSMENT WORK × 0.50 = Total $ value of worked claimed.

Note:
- Work older than 5 years is not eligible for credit.
- A recorded holder may be required to verify expenditures claimed in this statement of costs within 45 days of a request for verification and/or correction/clarification. If verification and/or correction/clarification is not made, the Minister may reject all or part of the assessment work submitted.

RECEIVED
SEP 19 1997 11:30
GEOSCIENCE ASSESSMENT OFFICE

Certification verifying costs:

I, CHRISTINE PETCH (please print full name), do hereby certify, that the amounts shown are as accurate as may reasonably be determined and the costs were incurred while conducting assessment work on the lands indicated on the accompanying Declaration of Work form as SR. FIELD GEOLOGIST (recorded holder, agent, or state company position with signing authority) I am authorized to make this certification.

Dear Sir or Madam:

Submission Number: 2.17658

Subject: Transaction Number(s):		**Status**
	W9760.00350	Approval

We have reviewed your Assessment Work submission with the above noted Transaction Number(s). The attached summary page(s) indicate the results of the review. WE RECOMMEND YOU READ THIS SUMMARY FOR THE DETAILS PERTAINING TO YOUR ASSESSMENT WORK.

If the status for a transaction is a 45 Day Notice, the summary will outline the reasons for the notice, and any steps you can take to remedy deficiencies. The 90-day deemed approval provision, subsection 6(7) of the Assessment Work Regulation, will no longer be in effect for assessment work which has received a 45 Day Notice.

Please note any revisions must be submitted in DUPLICATE to the Geoscience Assessment Office, by the response date on the summary.

If you have any questions regarding this correspondence, please contact Steve Beneteau by e-mail at benetest@epo.ndm.gov.on.ca or by telephone at (705) 670-5855.

Yours sincerely,

Symbols

CONTACTS
- Outcrop (small, observed, inferred, boulder/float)
- Geological Boundary (observed, approximate, assumed)
- Geological Boundary (gradational, gradationally inferred)
- Fault Contact (defined, approximate)

MEASUREMENTS
- Bedding with tops known (horizontal, inclined, vertical, overturned, dip unknown)
- Bedding with tops unknown (inclined, vertical, dip unknown)
- Plane top (horizontal, inclined, vertical, overturned, dip unknown)
- Syncline top
- Antiformally, gradationally, stoss-up or culmination (horizontal, inclined, vertical, dip unknown)
- Lineation (No. of trials = observation – S1, S2, S3)
- Jointing (horizontal, inclined, vertical, dip unknown)
- Lineation (horizontal, inclined, vertical)
- Folding – defined folds: S fold, Z fold, multiple S, multiple Z)
- Folding – undetermined type
- Fault (defined, approximate, assumed) (inclined, vertical, movement w/(stoss on downthrown side)
- Fault (Geophysically inferred, Lineament Inferred)
- Thrust Fault (defined, approximate, assumed) (teeth indicate upthrust side)
- Shear zone
- Dyke, vein (defined, approximate, assumed)
- Anticline, Antiform (with or without plunge, overturned)
- Syncline, Synform (with or without plunge, overturned)
- Stoss vector (Direction known, unknown) (numbers indicate relative age)
- Unit of Geological Mapping
- Layering, Direction

PHYSICAL WORK
- Mineral Occurrence
- Trench (1:250,000 =, 1:5,000 –)
- Diamond Drill Hole (vertical, inclined, collar located, collar unlocated)
- Overburden Drill Hole
- Mine, quarry or glory hole (active, abandoned)
- Shaft (vertical, inclined, raise, winze)
- Adit, Ramp
- Rock Dump, Tailings
- Gravel Pit (active, abandoned)

CULTURAL AND PHYSIOGRAPHIC FEATURES
- All weather road (paved, gravel)
- Road (fair, poor)
- Trail
- Buildings
- Campsite
- Power Line (major line, regular line)
- Telephone Line (landline, wireless)
- Railroad Track
- Tunnel
- Bridge
- River (open, rapids)
- Intermittent Stream
- Lake
- Swamp
- Esker
- Claim Post (OLS surveyed, Inspected survey, located, unlocated, witness, in holes)
- Grids (current grid, old grid)
- Survey Pin (located, unlocated)
- Lot/Concession Corner Pin (located, government defined)
