LIST OF MAPS

SUMMARY

The Glen Auden Resources property consists of two separate claim groups which lie along strike to the east and west of the Tarzan/Noranda J.V. Joburke Mine Project, all of which are situated in Keith Township (Figure 2). The western group is comprised of 71 claims staked by Glen Auden and 22 claims subject to an option agreement (the Meunier Claim Group). The eastern group consists of 63 claims (Groundhog claims) staked by Glen Auden which border the Groundhog River. The property is situated in the North Swayze metavolcanic-metasedimentary greenstone belt and is located 85 km southwest of Timmins, Ontario (Figure 1).

Detailed geological mapping was carried out on the eastern Groundhog claims from June 17 to June 30 and October 12 to October 17 of 1989. Major rock types found on the property were mapped as mafic and intermediate metavolcanic rocks, felsic metavolcanic rocks with lesser outcroppings of mafic and ultramafic intrusives and sedimentary iron formation.

Fifty rock samples were collected and analyzed for gold and various trace and rare earth elements. Selected samples also underwent whole rock analysis. There were no anomalous gold values to report. Four samples had anomalous copper values between 1160 and 7920 ppm and four samples had anomalous nickel values between 1080 and 1430 ppm. These copper and nickel anomalies came from mafic to ultramafic rocks which straddle the CN railway tracks. A further discussion of assay results can be found on page 13.

Induced polarization and magnetometer surveys were completed on the Groundhog claims from August 8 to September 7, 1989 and from October 14 to October 16 of 1989. The results of these surveys will be discussed later in this report.

Further exploration is recommended in two phases. Phase I begins with examining existing core, stored at the core library in Timmins, from diamond drill programs conducted on the property by previous workers (see section on Previous Work). Detailed relogging and sampling of this core is not possible because only representative samples of core from each hole is stored at the regional core library. Trenching and stripping complete Phase I for a budget of $37,000. Phase II consists of diamond drilling of target areas as outlined in the report and is budgeted at $130,900. The total proposed budget for the Groundhog claims is $167,900.00.

Reconnaissance sampling and induced polarization and magnetometer surveys were also completed on the Meunier claim group in 1989. The sampling program was carried out from June 14 to June 16 of 1989. The purpose of the sampling program was to investigate specific geophysical expressions and to resample weakly anomalous areas of gold tenure found by Garner, 1987 (see Report on the Geology of the Meunier claim group, Don Garner, 1987). Eleven rock samples were collected and analyzed for Au, copper and zinc. One anomalous Au value of 30 ppb came from a banded Fe formation. Weak copper anomalies between 150 and 200 ppm also occurred in the iron formation rocks. Further exploration for the Meunier Claim group is recommended in two phases. Phase I consists of trenching and stripping and a proposed budget of $36,400.00 is recommended. A diamond drilling program will complete Phase II at a cost of $71,500. A total budget of $107,900 is proposed for the Meunier 22 claims and brings the total cost of further exploration on Glen Auden's property to $275,800.

INTRODUCTION

Robert S. Middleton Exploration Services Inc. was contracted by Glen Auden Resources Limited to carry out geological mapping programs on Glen Auden's property in Keith Township, Porcupine Mining Division, approximately eighty-five kilometers southwest of Timmins, Ontario (Figure 1). The geological mapping was carried out from June 14 to June 30 and October 12 to October 17 of 1989, and was completed by traversing cut lines of a controlled grid on both the Meunier and Groundhog claims.

Rock samples were collected and sent to X-Ray Assay Laboratories, Toronto for geochemical analysis. All the samples were analyzed for gold, with selected samples being assayed for copper, nickel, zinc and whole rock analysis. Table 1 gives the method and detection limit for each element.

The purpose of this program was to determine the geology of the property in detail and to study its potential for gold mineralization.

For a list of claim numbers and their respective expiry dates please refer to Table 2.

LOCATION, ACCESS, FACILITIES

The Glen Auden property is situated in Keith Township and is located approximately 85 km southwest of Timmins, Ontario (Figure 1).

The western group Keith 71 and Meunier 22 claims are accessed via the Foleyet Lumber Road which extends southwards from Highway 101. The base line of the Meunier grid was extended 300m to intercept the road at a point 12 km south of the highway. Access to the Groundhog claims is via road 616 south from Highway 101 to the west shore of the Groundhog River.

TOPOGRAPHY AND VEGETATION

There is generally little topographic relief on the Glen Auden property. Several south west trending eskers occur in the northeastern section of the Keith 71 claim group and rise approximately ten to twenty meters above the surrounding terrain. Deposits of sandy boulder till flank the low ridges and form some of the more prominent features on the property.

Vegetation on the property is mainly mixed forest of poplar, birch, balsam and spruce. Low lying areas of cedar and alder swamp occur in all claim groups. The western part of the Keith 71 claim group has been recently clear cut and replanted with pine trees.

PREVIOUS WORK

The following description of previous work has been compiled from reports by Don Garner (1987) and Margaretha Zeeman (1988) on the geology of the Glen Auden property (see references).

The earliest reported work in the area was by W.A. Parks from the Ontario Bureau of Mines in 1899. He mapped the area around Horwood and Ivanhoe Lakes. This area was later remapped by the forerunner agencies of the O.G.S. by W.G. Miller (1902), T.L. Tanton (1916), W.W. Todd (1924) and K.V. Prest in 1947 whose map is the most detailed.

Consolidated Mining and Smelting Company

In 1946, Consolidated Mining and Smelting Company performed geological mapping on four patented claims (52450, 52451, 52452, 52453) adjacent to and west

of the Groundhog claims. The area was mapped as andesite and rhyolite with an east-west trending iron formation 200' wide at the bend of the Groundhog River.

Joburke Mine

In 1946, Joseph Burke and Maynard Bromley staked a gold showing approximately 5 km east of the Meunier claims for Rush Lake Gold Mines. Since the 1970's the Joburke Mines has produced 390,000 tons at 0.107 oz/ton Au and has reserves of 500,000 tons at 0.13 oz/ton Au.

The Hoyle Mining Company

Also in 1946, The Hoyle Mining Company drilled six holes on the present Groundhog claims 1035717, 1071623, 1035724 (see Groundhog Geology Map: South Sheet). Diamond drill hole KG#4 yielded samples which assayed up to 0.005 oz/ton Au. Hole KG#6 intersected a 26 foot wide quartz-carbonate vein hosted by andesite which assayed 0.01 oz/ton Au. Core sections are stored at the Timmins Core Library.

Wejack Gold Mines Ltd.

In 1947, eight holes were drilled by Wejack Gold Mines Ltd. in a north-south fence pattern in the southeastern part of the Meunier 22 claim group and extend beyond the southern boundary of the claims. 4,000 feet of stratigraphic information was obtained and later summarized by Prest in his 1948 geological compilation of the Keith Township area.

Purdy Mica Mines Ltd.

Purdy Mica Mines drilled ten holes on the present Groundhog claims in 1947. Nine holes were drilled on claims 1087293, 1035694 and 1035695, with the tenth hole being drilled south of the CN tracks on claim 1035701. PM#1, located on the Groundhog Drill Hole Location Map, is the only hole for which assays are reported and included a five foot sample on weakly sheared basic lava assaying 0.005 oz/ton

Au. Between 1947 and 1955, Purdy Mica Mines drilled an additional fifteen holes south of the CN rail tracks on present claims 1087290, 1087291 and 1087292. These holes intersected locally carbonatized andesite with pyrite, pyrrhotite and chalcopyrite mineralization. No gold assays were reported. Drill core logs are available at the Regional Core Library in Timmins.

Algoma Ore Properties

In 1960, Algoma Ore Properties completed a magnetometer survey on the west side of Groundhog River and north of the CN tracks. The company also drilled two holes, one on the west side of the river and on the east side of the river which would place it on present claim 1071623. The eastern drill hole intersected banded iron formation throughout its depth. The core from this hole is stored on patented claim 52450, 200 feet from the river.

Keevil Mining Group

In 1965, the Keevil Mining Group acquired a group of claims in Keith Township which included the northern part of the Meunier property. Ground magnetometer and electromagnetic surveys outlined a strong conductor 2,400 feet long trending N75E in the north-eastern part of the Keevil property. Mapping and trenching revealed graphitic, brecciated sediments with zones of sulphides. No economic mineralization was reported.

Kukatush Mining Corporation Ltd.

Kukatush Mining Corporation Ltd. drilled four holes in 1966, two of which occur on the present Glen Auden Resources Limited Groundhog property. Drill hole KM#7 located on claim 1035740 intersected andesite at the top and rhyolite at the bottom of the hole. No significant mineralization was encountered. Diamond drill hole KM#9 located on claim number 1087293 intersected chloritic diorite at the top of the hole and then volcanic tuff at the lower end. A 22 foot section of tuff,

contained blue quartz and fine pyrite but no assays were reported. The drill core described can be found in the Core Library in Timmins.

Hollinger Mines Ltd.

In 1971, Hollinger Mines Ltd. drilled three holes for a total of 271 meters in the northern half of the Meunier 22 claim group. The company was apparently drill testing EM conductors outlined by the Keevil Group. All three holes encountered graphite but no assay information was available from the government files.

Dome Exploration

In 1980, Dome Exploration conducted a ground magnetometer survey over their property which included the northern part of Glen Auden's Groundhog property. A very strong mag high trending east-northeast was outlined and interpreted to be magnetic iron formation. This conclusion coincides with outcrops of iron formation mapped on Groundhog claims 1035785 and 1035733 (L19W 0+50N).

Glen Auden Resources Limited

Dighem Surveys and Processing was contracted in 1988 to conduct airborne magnetic and VLF-EM surveys over the Keith 71 claim group. Several east-west and south-east trending magnetic high anomalies were interpreted to represent either iron formation or high magnetic mafic volcanic flow sequences.

Also in 1988, Robert S. Middleton Exploration Services Inc. was contracted to conduct a reconnaissance mapping program over Glen Auden's entire property. The basic geology of the area was identified and general areas of alteration and sulphide mineralization were delineated.

Further exploration was recommended in the form of ground magnetic and induced polarization surveys and detailed geological mapping and sampling.

Sangold Project

At the present time the Sangold Project operates a few kilometers west of Glen Auden's Groundhog claims. Extensive stripping and sampling have been carried out and diamond drilling is in progress. Significant gold assays have been obtained from quartz-carbonate veins containing pyrite and chalcopyrite mineralization.

REGIONAL GEOLOGY

The Keith Township area was mapped by V.K. Prest and reported by the Ontario Department of Mines in 1950 (ODM Vol.LIX, Pt. VII). The area is situated on an east-west trending metavolcanic-metasedimentary belt known as the Archean Swayze greenstone belt. The belt is predominantly comprised of Keewatin mafic and intermediate to felsic metavolcanic sequences, and thin associated epiclastic sedimentary rocks, intrusive rocks and iron formation (Prest, 1950)(Figure 3). The local stratigraphy trends east-west with a steep north dip. Oxide and sulphide facies iron formations strike across the region paralleling the trend of the mafic and felsic volcanic sequences (Figure 3). Intruding the mixed complex of volcanic and sedimentary rocks are sill like bodies of dioritic composition. The sill and dyke character of these diorites is readily apparent when associated with magnetically quiet metasediments. Ultramafic intrusive rocks, believed to be younger than the diorites appearing as serpentine, may represent altered diorites and/or peridotites (Prest, 1950). These rocks contain abundant carbonate alteration due to the carbonate being released during metamorphosis of the serpentine (Prest, 1950). Granite plutons occur to the north and south of the greenstone belt. Proterozoic diabase intrudes all of the rocks of the region and generally trend north-northwest.

A series of east-west orientated faults was mapped by Prest (1950) along the margin of a felsic sequence and which extends into the Penhorwood Township. Milne (1972) who mapped the Penhorwood Township area has discussed the possibility that these structures represent the western extension of the Destor-Porcupine Fault.

Pyke (1987) has proposed that the supracrustal sequences of the Swayze greenstone belt are similar, texturally and compositionally, to the volcanic sequences of the Timmins Mining Camp. Based on these interpretations of the geology of the Archean Swayze greenstone belt, it is suggested that the Glen Auden property and the adjoining Joburke Mine lie along the western extension of the Destor-Porcupine Fault or a major splay of it (Garner, 1987).

The following geological time table illustrates the age relations (Prest, 1950);

PROPERTY GEOLOGY

MEUNIER 22 CLAIMS

The geology of the twenty-two Meunier claims was mapped by Garner (1988). The claim group is underlain by a thick sequence of tholeiite mafic metavolcanic rocks with metasedimentary rocks occurring in the south east corner of the property. Oxide iron formation was located in the north-eastern part of the property but the continuity of the unit could not be traced. Rocks encountered during the 1989 sampling program included mafic metavolcanic rocks and the oxide iron formation.

Mafic Metavolcanic Rocks

These volcanic rocks underlie the majority of the Keith 71 claims and Meunier 22 claims property and include massive, pillowed and foliated varieties. Outcrops are dark green to grey-green, fine grained and massive to weakly foliated in texture. Mineral assemblages are comprised of plagioclase and actinolite with minor chlorite. Strong iron carbonatization was seen in several outcrops.

Iron Formation

This rock consists of alternating narrow bands of magnetite rich and quartz rich material. The bands vary in width from two centimeters to less than half of a centimeter. Thin orange, rusty bands occasionally occur at the margin between the magnetite and chert bands. The iron formation is weakly deformed with small local isoclinal folding.

GROUNDHOG CLAIMS

Key geological features on the Groundhog claim group which were determined from geological mapping or interpreted from geophysical data are indicated, along with rock sample locations, on Map 4 (Geology Map: Groundhog Grid).

In general, the geology of the property is comprised of an east-west trending sequence of Keewatin mafic and intermediate to felsic metavolcanic rocks, iron formation and intrusions of granite, diorite and serpentine, quartz-feldspar porphyry and diabase.

ROCK TYPES

Mafic Metavolcanic Rocks

These rocks are dark green to green black, fine to medium grained and include massive, pillowed and foliated varieties. The rocks were mapped as andesite and basalt in composition. Chlorite content was low in the massive rocks but significantly higher in the foliated types. Strong iron carbonate alteration was found in several outcrops of the volcanic rock, usually near the contacts with ultramafic intrusions. The metamorphic grade throughout this volcanic sequence is upper greenschist to locally, amphibolite facies. Mineral assemblages which characterize these rocks are plagioclase, actinolite, and chlorite.

Intermediate Metavolcanic Rocks

These volcanic rocks comprise a minute part of the map area. They are pale green to green, fine grained and massive in texture. Compositionally they range from andesite to dacite. These rocks are relatively unaltered but do exhibit weak chlorite and silica alteration.

Felsic Metavolcanic Rocks

The rocks that comprise this group form a wide east-west trending sequence across the property. They are light pinkish to pale white and are made up of lavas, tuffs and brecciated forms of the latter. Most are rhyolitic in composition but some of these volcanic rocks have been altered to a sericite schist.

Sedimentary Rocks

Banded iron formation is the only sedimentary unit observed on the Groundhog claim group. This iron formation is very similar to the unit seen on the Meunier 22 claims and is possibly an extension of the same iron formation. Narrow bands of magnetite rich and quartz rich material characterize this rock.

Ultramafic Rocks

From field mapping these rocks have been identified as serpentinites and talc chlorite schists. Originally these rocks appear to have been in the range of pyroxene diorite, peridotite-picrite, olivine gabbro and diabasic diorite (Prest, 1950). Characteristically they are strongly foliated, fine grained and have a soft, soapy texture. Color ranges from pale green to green-grey. Major mineral components are pyroxene, olivine, tremolite and talc.

Early Mafic and Intermediate Intrusive Rocks

These rocks consist of medium grained diorite sills and dykes. They resemble coarse grained mafic volcanic rocks and have been misinterpreted as such (Prest, 1950). Mineralogically, major components are plagioclase, hornblende with accessory quartz and biotite. Surface weathers to a light brown color and fresh surface is equally brown.

Early Felsic Intrusive Rocks

These are narrow, elongate granitic bodies that have been mapped as quartz-feldspar porphyry. The rock is composed of coarse grained feldspar and quartz grains in a fine grained ground mass of feldspar, quartz and muscovite. This unit has been traced across the southern part of the claim group, both north and south of the CN rail tracks.

Late Mafic Intrusive Rocks

Diabase dikes intrude all of the above mentioned rock types. These dykes vary from quartz diabase and porphyritic diabase and trend north-northwest. Characteristically the rock is dark grey, medium grained, and has a light red brown weathered surface.

PLEISTOCENE GEOLOGY

Approximately eighty-five percent of the Glen Auden property is covered by a blanket of glacial overburden and lacustrine sediments of variable thickness. Deposits of sandy boulder till occur as low ridges, the clast composition of which is both granitic and volcanic in composition. This boulder till can be observed in the western part of the Meunier 22 claim group where an area has been bulldozed for jack pine re-forestation. Topographic glacial features in Keith Township such as eskers as well as glacial striae suggest an ice movement of approximately north to south (Prest, 1950).

STRUCTURAL GEOLOGY

Measurements of the strike and dip of outcrops on the Groundhog claims shows a predominantly east-west trend in foliation. The mafic volcanic and iron formation rocks to the north were massive with some outcrops showing weak foliation. The degree of foliation increases southward where very strong foliation is noted in the mafic to ultramafic rocks situated in claims 1087290, 1087291, 1087292, 1035695. Strong slatey cleavage was observed in sericite schists interpreted to represent felsic volcanic rocks. This sericitized zone of felsic volcanic rock is located north of the mafic to ultramafic rocks on claim 1087293. Several sets of quartz veins infill, tension fractures were mapped in the mafic

volcanic rocks in the southern part of the grid. Quartz vein occurrences at L0W-1600S, L5W-1850S and L8W-1925S have similar strikes and dips of Az 030°-040°/40-45N and all fall along a coincident strike plane. These quartz veins may represent intermittent outcrops of a continuous vein system crosscutting the host mafic volcanic rocks.

Prest (1950) mapped a series of north-south and east-west trending faults which would be located on the present Groundhog claims 1087290, 1087291 and 1071623. These faults were not observed during the 1989 mapping program.

ALTERATION AND MINERALIZATION

The 1989 mapping program of the Groundhog claims confirmed reports by Zeeman (1988) that significant hydrothermal alteration and high strain deformation is confined to the mafic volcanic and ultramafic rocks located in the south-central part of the property which straddles the CN rail tracks. These rocks have been altered to talc-chlorite schists. Moderate to strong iron carbonatization and minor amounts of green chromium mica (fuchsite) occur in these talcose mafic to ultramafic rocks. Pyrite, pyrrhotite and chalcopyrite are the major sulphides present in the mafic to ultramafic rocks. Occurrences vary as 2-3% fine grained disseminated sulfides, thin stringers and localized 10-20% massive pyrite, with minor chalcopyrite and pyrrhotite in gossanized rock. Within this altered mafic to ultramafic zone occurs minor outcrops of diabase, magnetic diorite and a quartz-feldspar porphyry dyke that has been traced east-west for over 1500 meters.

The quartz-feldspar porphyry dyke intrudes the altered mafic and ultramafic rocks and parallels the east-west strike of the volcanic host rocks. The dyke is weakly to moderately carbonatized and contains up to 2% disseminated pyrite. Iron

sulfides also occur as massive clots and elongate pods up to 1 cm long at the margin of the dyke.

Alteration and mineralization of rocks on the Meunier 22 claim group consists of carbonatization of tholeiitic basalts. Pyrite and pyrrhotite occur as 2-3% disseminated sulfides in the mafic volcanic rocks and up to 5% as massive stringers and clots in the iron formation located in the north of the property.

DISCUSSION OF ASSAY RESULTS

During the mapping of the Groundhog claims, fifty samples were collected for assay for gold with selected samples assayed for copper, zinc, nickel and whole rock analysis. All samples are located on "Geology Map: Groundhog Grid."

Four samples (0435, 0440, 0451, 5846) had anomalous nickel values of 1100, 1280, 1080 and 1430 ppm respectively. All four of the anomalous samples were taken from hydrothermally altered mafic volcanic and ultramafic rock which contained 2-3% disseminated and massive pyrite and pyrrhotite. These samples occurred on claim numbers 1087290, 1087291, 1087292 and 1035695.

Four samples (0444, 0445, 0458, 0468) had anomalous copper values of 1390, 7920, 1160 and 4140 ppm respectively. The host rock for these anomalies is the mafic volcanic and ultramafic rocks as was the case for the nickel anomalies. The rocks are altered to carbonatized talc chlorite and chlorite schists, which contain trace to >5% disseminated and massive pyrite, chalcopyrite and pyrrhotite. These samples were located on claims 1087290 and 1087291.

The eleven samples taken from the Meunier 22 claim group were assayed for gold, copper and zinc. The assay values were low and only two samples were designated as having anomalous gold and copper values. Sample 5838 was taken from a strongly gossaned and hematite stained banded iron formation and recorded

gold and copper assays of 30 ppb and 150 ppm. Sample 5841 was also taken from an outcrop of oxide iron formation rock with blue-black quartz veins which contained trace disseminated pyrite. This sample assayed 200 ppm copper and weak zinc of 450 ppm.

These two samples were taken from banded oxide iron formation located in the south-east part of the property on claim 946201. An area between L13+50E 2+80S and L14+20E 2+60S of the Meunier Grid has been targeted for a trenching and stripping program to enable detailed sampling of the bedrock.

GEOPHYSICAL SURVEYS AND INTERPRETATION

Introduction

From August 8, 1989 to September 7, 1989, and from October 14 to October 16, 1989, a program of geophysical surveying was conducted on the Keith Township Property for Glen Auden Resources Limited of 301-121 Richmond Street West, Toronto, Ontario.

The geophysical survey consisted of total field magnetics and time-domain induced polarization.

The survey was conducted as a follow-up to an airborne electromagnetic survey done by DIGHEM (McConnell, 1988), and a geological report (Zeeman, 1988) which delineated structures and anomalies which might be indicative or associated with possible economic mineral deposits.

Induced Polarization

Theory

The induced polarization (IP) and resistivity exploration methods are electrical methods based on measuring the response of the earth to an applied direct current.

The principle is to apply a known electric current to the earth, and measure the electric potential created by it at the survey location. The resistivity, a bulk property of the rock itself, is calculated from the difference between the applied current and the measured potential, corrected for the geometry of the current and potential electrode configuration.

The induced polarization measurement is based on the "over-voltage" effect. Most of the electric current carried by the earth is conducted by the flow of ions in the solutions filling the pore spaces in the rock. At the surface of any metallic particle in the path of current low, the ionic flow in the solution is changed to an electronic flow in the metal. In the process of the change, an electric charge of trapped ions is built up at the surface of the metal, storing a small voltage. If the voltage increases, the apparent resistance of the rock also increases. If the applied current flow is decreased or stopped, the voltage will create a potential in the opposite direction to the original applied current, and start a current flowing in the opposite direction.

In time domain induced polarization the applied current is abruptly stopped, and the reverse potential created by the over-voltage effect is measured over time as it quickly decays. The definition of chargeability is:

$$M = \frac{V\ (t = \infty)\ -\ V\ (t = 0)}{V(t = \infty)}$$

where $V(t = 0)$ is the voltage at turnoff, and $V(t = \infty)$ is the late-time voltage. This is usually measured over a certain time period after turn-off as an integral of voltage over time, corrected for the length of the time period, and normalised to the voltage at time 0. It is usually expressed in millivolts per volt (mV/V).

The over-voltage charge taken time to build-up or decay, so that if the applied current is caused to oscillate more and more frequently, the apparent

resistance will decrease, as the over-voltage does not have time to build at higher frequencies. This effect is used to measure the IP effect in frequency domain IP surveys, wherein the current is applied at two or more frequencies, and the "percent frequency effect" (PFE) is calculated from the change in resistivities (P) between the different frequencies.

$$PFE = \frac{P\ (low\ freq) - P\ (high\ freq)}{P\ (high\ freq)} \times 100\%$$

Although not identical, for most purposes the PFE is approximately equal to the chargeability.

Because the IP effect responds to effects on small metallic particles, it is particularly useful for detecting disseminated metallic minerals. Also because of this, it will respond strongly to the "membrane polarization" created by the electric charges resident on clay particles or layered or fibrous minerals.

Field Method

The survey was conducted using a pole-dipole array with a dipole length of 50m and array spacings of n = 1,2,3,4 dipole. This array configuration involves having a dipole for the receiver measuring Vp, the potential and a single current transmitter electrode on the grid, separated from the receiver dipole by each 'n' interval in turn. The other current electrode, 'the infinity' is situated 2 kilometers or more from the grid.

For this survey the measurements were taken in the time domain, so the transmitted current was a bipolar on-off square wave with each on or off lasting two seconds. Measurements of resistivity and chargeability were taken.

Magnetics

Theory

The magnetic method is based on measuring alteration in the shape and magnitude of the earth's naturally occurring magnetic field caused by changes in the magnetization of the rocks in the earth.

These changes in magnetization are due mainly to the presence of the magnetic minerals, of which the most common is magnetite, and to a lesser extent ilmenite, pyrrhotite, and some less common minerals.

Magnetic anomalies in the earth's field are caused by changes in two types of magnetization: induced and remanent (permanent). Induced magnetization is caused by the magnetic field being altered and enhanced by increases in the magnetic susceptibility of the rocks, which is a function of the concentration of the magnetic minerals.

Remanent magnetism is independent of the earth's magnetic field, and is the permanent magnetization of the magnetic particles (magnetite, etc.) in the rocks. This is created when these particles orient themselves parallel to the ambient field when cooling. This magnetization may not be in the same direction as the present earth's field, due to changes in the orientation of the rock or the field.

The most common method of measuring the total magnetic field in ground exploration is with a proton precession magnetometer. This device measures the effect of the magnetic field on the magnetic dipole of hydrogen protons. This dipole is caused by the "spin" of the proton, and in a magnetometer these dipoles in a sample of hydrogen-rich fluid are oriented parallel to a magnetic field applied by an electric coil surrounding the sample. After this magnetic field is removed, the dipoles begin to precess (wobble) around their orientation under the influence

of the ambient earth's magnetic field. The frequency of this precession is proportional to the earth's magnetic field intensity.

Field Method

The magnetics data was collected with an EDA PPM 350 proton procession magnetometer, which measures the absolute value of the earth's magnetic field to an accuracy of ± 1 gammas. The magnetometer was carried down the survey line by a single operator, with the sensor mounted on an aluminum pole to remove it from any surface geologic noise. Readings were normally taken at 25m intervals, and at 12.5m intervals where a high gradient or anomaly was observed by the operator.

The readings were corrected for changes in the earth's total field (diurnal drift) with an EDA PPM 400 base station magnetometer, which recorded readings every 20 seconds as the survey was being conducted. The data from both magnetometers was then dumped with a computer and base corrected values were computed.

Personnel and Equipment

The following personnel from Middleton Exploration Services Inc. conducted the geophysical surveys:

Richard Lachapelle, Geophysicist
Brad Malpage, Technician
Tom V. Cardinal, Technician
Paul Edwards, Labourer
Melvin Booth, Labourer
Rodney Booth, Labourer
Tom Bolton, Technician

The equipment used were a Scintrex IPR-11 time-domain induced polarization receiver, a Scintrex TSQ-3, 3 kw transmitter, a Huntec 7.5 kw transmitter, an EDA Instruments PPM 350 field magnetometer and an EDA Instruments PPM 400 base

station magnetometer. Specifications for these instruments are included in Appendix A.

GROUNDHOG CLAIMS

Survey Statistics

The line cutting totalled 55.0 km on which 25.95 line km of time-domain induced polarization and 35.32 line km of total field magnetics were surveyed.

The surveys required 29 days to complete, of which 3 days were lost due to inclement weather and 2.5 days were used for mobilization/demobilization.

Interpretation
North Part (Map 1)
Magnetic Survey

The magnetic survey delineated three domains of distinct magnetic signature, denoted M1, M2 and M3 respectively.

Magnetic domain M1 is characterized by a very high and disturbed magnetic signature ranging from approximately 2000 Gammas above base level to 13000 Gammas above base level. This domain is intersected by a northwesterly to westerly trending interpreted fault extending from approximately station 4+50N on line 19+00W to station 3+00N on line 9+00W. This domain is interpreted to possibly represent an oxide-facies iron formation with magnetic horizons.

Magnetic domains M2 are oblong to spheric-shaped and are characterized by a medium magnetic signature of approximately 800 to 1200 Gammas above base level. These domains are interpreted to possibly represent mafic to ultramafic intrusive rocks.

Magnetic domain M3 is characterized by a quiet magnetic signature ranging from approximately 200 Gammas below base level to 600 Gammas above base level. This domain is intersected by an extensive northeasterly to easterly trending

interpreted fault, extending from approximately station 2+75S on line 18+00W to station 3+00N on line 0+00. Domain M3 is also intersected by the previously discussed northwesterly to westerly trending interpreted fault. Domain M3 is interpreted to possibly represent mafic volcanic units.

Induced Polarization Survey

The induced polarization survey delineated several chargeability axes as well as a few isolated chargeability anomalies. The former are denoted CIII, CIV, CVA and CVB.

CIII is a weak to strong chargeability anomaly axis extending from approximately station 1+00N on line 20+00W to station 1+25N on line 17+00W. This anomaly axis is located within domain M1 and is therefore interpreted to possibly represent sulfide and/or magnetite horizons within the oxide-facies iron formation.

CIV is a weak chargeability anomaly axis located within domain M3, and extends from approximately station 2+75S on line 19+00W to station 1+50S on line 13+00W, and is also sub-parallel to the major northeasterly to easterly trending interpreted fault discussed earlier.

Anomaly axis CV consists of two splays, denoted CVa and CVb, that are weak chargeability anomaly axes extending respectively from approximately station 2+25N on line 19+00W to station 3+75N on line 15+00W and from approximately station 4+00N on line 19+00W to station 3+75N on line 15+00W. Both splays are located within domain M3. Axis CVb is sub-parallel to the major northwesterly to westerly trending interpreted fault discussed earlier.

Axes CIV and CV are interpreted to possibly represent sulfide horizons within mafic volcanic rocks.

Several isolated anomalies worth mentioning are:

- *at station 5+75N on line 3+00W*
- *at stations 2+50S and 4+50S on line 11+00W.*

These anomalies are interpreted to be of the same nature as CIV and CV.

South Part (Map 2)
Magnetic Survey

The magnetic survey delineated three domains of distinct magnetic signature denoted M4, M5 and M6. Domain M4 is characterized by a quiet magnetic signature ranging from approximately 1500 to 2000 gammas above base level. Domain M5 is characterized by a very quiet magnetic signature of approximately 1000 gammas above base level. Both of these domains are interpreted to possibly represent mafic volcanic units.

Domain M6 is characterized by a very disturbed magnetic signature ranging from approximately 1500 to 3000 gammas above base level. This domain is interpreted to possibly represent a series of easterly trending intercalated mafic and ultramafic units.

Induced Polarization Survey

The induced polarization survey delineated two chargeability anomaly axes denoted CI and CII within domain M6.

CI is a weak to strong chargeability anomaly axis extending from approximately station 20+25S on line 15+00W to station 20+25S on line 1+00W. CII is a weak chargeability anomaly axis extending from approximately station 21+00S on line 7+00W to station 20+50S on line 5+00W. These axes are interpreted to represent sulfide units within the intercalated mafic and ultramafic units. Ground geological investigation by Burton revealed that "sulfide stringers within a quartz feldspar porphyry" were observed in the immediate vicinity of CI and CII.

CONCLUSIONS AND RECOMMENDATIONS

Groundhog Claims

Two zones of interest have been delineated by detailed geological mapping and geophysical data. The first zone occurs in the northern part of the claim group and consists of banded iron formation in a mafic volcanic sequence. This iron formation was sampled and assayed the highest gold value of 38 ppb. The scarcity of outcrop prevented the iron formation from being traced but was delineated by the magnetometer survey and found to extend from L19W 50N to L7W 300N. Induced polarization chargeability anomalies over the iron formation suggest the possible presence of localized sulfide facies.

The most significant alteration and deformation occurs in the south-central portion of the claim group on claims 1087290, 1087291, 1087292 and 1035695 within an east-west trending zone of mafic volcanic to ultramafic rocks. These rocks are commonly talcose, chloritic and show varying degrees of carbonatization. This sequence of rocks as well as the felsic volcanic rocks to the north may be stratigraphically related to a similar sequence of rocks found at the Joburke Mine, located a few kilometers to the west of the Groundhog claim group. Included in this zone of mafic and ultramafic rocks is a north-east trending series of fracture fill quartz veins and the quartz feldspar dyke which warrants further investigation due to its varying degrees of carbonatization and local pyritic zones.

This southern zone of hydrothermal alteration and strong deformation is recommended to be further investigated by mechanical trenching and diamond drilling.

The induced polarization surveys delineated several chargeability anomaly axes coincident with magnetic highs and isolated chargeability anomalies worthy of further work. The anomalies of particular interest are the weak to moderate

anomalies located in the interpreted mafic volcanic rocks. Anomaly axes CIV and CV should be investigated by means of diamond drilling in order to determine their cause and possible economic mineral potential. Selected areas of axis CI and CII should be stripped since a shallow overburden cover was observed in the western part of CI and parts of CII. The isolated chargeability anomalies located at station 5+75N on line 3+00W and at stations 2+50S and 4+50S on line 11+00W should be investigated by means of diamond drilling and/or trenching if possible.

Existing diamond drill core from previous work on the Groundhog claims should be examined as this information may be vital to the targeting of future drill hole sites. However, it should be noted that such information may be of limited value as only representative samples of core from most of the previous drilling have been retained. The core is stored at the regional core library in Timmins, Ontario.

Meunier 22 claims

The cursory sampling and prospecting of the Meunier 22 claim group confirmed the presence of a banded iron formation to the north of the property. Assay of the iron formation showed weakly anomalous gold and copper values and should therefore be investigated further by means of stripping and trenching to effectively sample the bedrock. A program of diamond drilling is recommended contingent upon the results of the stripping and trenching. Further investigation of the carbonatized tholeiitic basalts in the southeast portion of the claim group is warranted, since this form of hydrothermal alteration is found in the tholeiitic basalts of the Timmins camp and is typical of Archean Lode gold deposits.

The following are budgets proposed for further exploration on the Groundhog claims and the Meunier 22 claims.

GROUNDHOG CLAIMS

BUDGET

Phase I

Examination of existing core	
1 Geologist - 2 days @ $300./day	$ 600.00
Trenching - backhoe-dozer	
14 days @ $1,200./day	16,800.00
1 Geologist	
14 days @ $300./day	4,200.00
1 Assistant	
10 days @ $200./day	2,000.00
Rock saw and sampling	3,000.00
Assaying	6,000.00
Subsistence: 14 days @ $100./day	1,400.00
Report	3,000.00
Subtotal	$ 37,000.00

Phase II

Diamond drilling	
4,000 feet @ $25./foot	100,000.00
Supervision	
1 geologist - 30 days @ $300./day	9,000.00
Assaying	4,000.00
Reports	3,000.00
Subsistence: 30 days @ $100./day	3,000.00
Contingency (10%)	11,900.00
TOTAL PHASES I & II	$167,900.00

MEUNIER 22 CLAIMS

BUDGET

Phase I

Trenching - Backhoe-dozer	
14 days @ $1,200./day	$ 16,800.00
1 Geologist	
14 days @ $300./day	4,200.00
1 Assistant	
10 days @ $200./day	2,000.00

CERTIFICATION

I, John A. Burton, B.Sc., of 38 Fourth Avenue, in the town of Schumacher, Province of Ontario, certify as follows concerning my report on the Keith Township, Ontario property of Glen Auden Resources Limited and dated January 15, 1990.

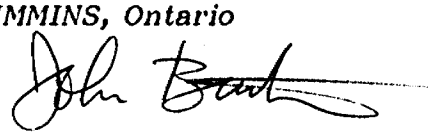
1. *I am a graduate of Mount Allison University, Sackville, New Brunswick, with a B.Sc. degree specializing in geology obtained in 1987.*

2. *I have been practising my profession in Canada for the past 3 years.*

3. *I have no direct or indirect interest in the properties, leases or securities of Glen Auden Resources Limited, nor do I expect to receive any.*

4. *The attached report is a product of:*
   a) *Data listed in the references;*
   b) *Previous work files at the Offices of the Ontario Ministry of Natural Resources;*
   c) *A personal visit to the property to conduct geological mapping.*

Dated this January 15, 1990
TIMMINS, Ontario



John A. Burton, B.Sc.

CERTIFICATION

I, Richard Lachapelle, of 136 Cedar Street South, in the City of Timmins, Province of Ontario, certify as follows concerning my report on the Glen Auden Resources Limited property in Keith Township, Province of Ontario and dated January 15, 1990:

1. *I am a junior member in good standing of l'Ordre des Ingenieurs du Quebec.*

2. *I am a graduate of l'Universite de Sherbrooke, Sherbrooke, Quebec with a B.Sc. degree in Physics, obtained in 1984.*

3. *I am a graduate of l'Ecole Polytechnique de Montreal, Montreal, Quebec with a B.Ing degree in Geological Engineering obtained in 1987.*

4. *I have been practising in Canada since 1987.*

5. *I have no direct interest in the properties, leases, or securities of Glen Auden Resources Limited, nor do I expect to receive any.*

6. *The attached report is a product of:*
   a) *Examination of data included in the report which was collected on the property concerned.*

Dated this 15th day of January, 1990
TIMMINS, Ontario

Richard Lachapelle, B.Sc.Ing.Jr.
Geophysicist

APPENDIX A

Technical Description of the IPR-11 Broadband Time Domain IP Receiver

Input Potential Dipoles	1 to 6 simultaneously.
Input Impedance	4 megohms.
Input Voltage (Vp) Range	100 microvolts to 6 volts for measurement. Zener diode protection up to 50V.
Automatic SP Bucking Range	± 1.5 V.
Chargeability (M) Range	0 to 300 mV/V (mils or 0/00)
Absolute Accuracy of Vp, SP and M	Vp; ± 3% of reading for Vp > 100 microvolts. SP; ± 3% of SP bucking range. M; ± 3% of reading or minimum ± 0.5m V/V.
IP Transient Program	Ten transient windows per input dipole. After a delay from current off of t, first four windows each have a width of t, next three windows each have a width of 6t and last three windows each have a width of 12t. The total measuring time is therefore 58t. t can be set at 3, 15, 30 or 60 milliseconds for nominal total receive times of 0.2, 1, 2 and 4 seconds.
VP Integration Time	In 0.2 and 1second receive time modes; 0.51sec. In 2 second mode; 1.02sec. In 4 second mode; 2.04 sec.
Transmitter Timing	Equal on and off times with polarity change each half cycle. On/off times of 1, 2, 4 or 8 seconds with ± 2.5% accuracy are required.
Header Capacity	Up to 17 four digit headers can be stored with each observation.
Data Memory Capacity	Depends on how many dipoles are recorded with each header. If four header items are used with 6 dipoles of SP, Vp and 10 M windows each, then about 200 dipole measurements can be stored. Up to three Optional Data Memory Expansion Blocks are available, each with a capacity of about 200 dipoles.
External Circuit Check	Checks up to six dipoles simultaneously using a 31Hz square wave and readout on front panel meters, in range of 0 to 200k ohms.
Filtering	RF filter, spheric spike removal; switchable 50 or 60Hz notch filters, low pass filters which are automatically removed from the circuit in the 0.2 sec receive time.
Internal Calibrator	1000 mV of SP, 200 mV of Vp and 2.43 mV/V of M provided in 2 sec pulses.

Technical Description of the IPR-11 Broadband Time Domain IP Receiver

Digital Display	Two, 4 digit LCD displays. One presents data, either measured or manually entered by the operator. The second display: 1) indicates codes identifying the data shown on the first display, and 2) shows alarm codes indicating errors.
Analog Meters	Six meters for: 1) checking external circuit resistance, and 2) monitoring input signals.
Digital Data Output	RS-232C compatible, 7 bit ASCII, no parity, serial data output for communication with a computer, digital printer, digital storage device or modem.
Standard Rechargeable Power Supply	Eight rechargeable NiCad D cells provide approximately 15 hours of continuous operation at 25°C. Supplied with a battery charger, suitable for 110/230V, 50 to 400 Hz, 10W.
Disposable Battery Power Supply	At 25°C, about 40 hours of continuous operation are obtained from 8 Eveready E95 or equivalent alkaline D cells. At 25°C, about 16 hours of continuous operation are obtained from 8 Eveready 1150 or equivalent carbon-zinc D cells.
Dimensions	345 mm x 250 mm x 300 mm, including lid.
Weight	10.5 kg, including batteries.
Operating Temperature Range	-20 to + 55°C, limited by display.
Storage Temperature Range	-40 to + 60°C.
Standard Items	Console with lid and set of rechargeable batteries, RS-232C cable and adapter, 2 copies of manual, battery charger.
Optional Items	Multidipole Potential Cables, Data Memory Expansion Blocks, Crystal Clock, SOFT II Programs, Printer, Cassette Tape Recorder, Disk Drive or Modem.
Shipping Weight	25 kg includes reusable wooden shipping case.

At Scintrex we are continually working to improve our line of products and beneficial innovations may result in changes to our specifications without prior notice.

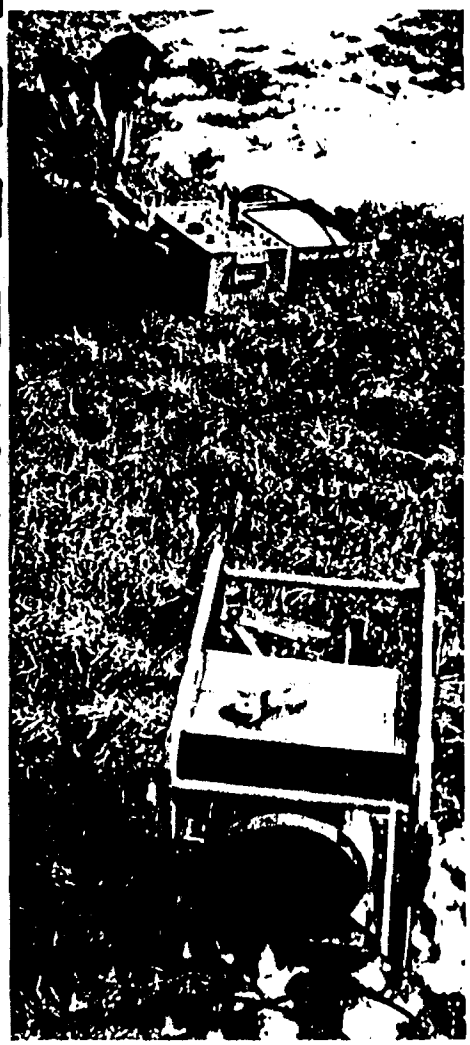
Technical Description of TSQ-3000W Time and Frequency Domain IP and Resistivity Transmitter



TSQ-3 transmitter with portable motor generator unit

Transmitter Console	
Output Power	3000 VA maximum
Output Voltages	300, 400, 500, 600, 750, 900, 1050, 1200, 1350 and 1500 volts, switch selectable
Output Current	10 amperes maximum
Output Current Stability	Automatically controlled to within ±0.1% for up to 50% external load variation or up to ±10% input voltage variation
Digital Display	Light emitting diodes permit display up to 1999 with variable decimal point; switch selectable to read input voltage, output current, external circuit resistance. Dual current range, switch selectable
Absolute Accuracy	± 3% of full range
Current Reading Resolution	10 mA on coarse range (0-10A) 1 mA on fine range (0-2A)
Frequency Domain Waveform	Square wave, continuous with approximately 6% off time at polarity change
Frequency Domain Frequencies	Standard: 0.033, 0.1, 0.3, 1.0 and 3.0 Hz, switch selectable Optional: any number of frequencies in range 0 to 5 Hz.
Time Domain Cycle Timing	t:t:t:t,on:off:on:off;automatic
Time Domain Polarity Change	each 2t; automatic
Time Domain Pulse Durations	Standard: t = 1, 2, 4, 8, 16 or 32 seconds Optional: any other timings
Period Time Stability	Crystal controlled to better than .01%. An optional high stability clock provides stabilization to better than 1 ppm over -20/ + 50° C.
Efficiency	.78
Operating Temperature Range	-30° C to + 50° C
Overload Protection	Automatic shut-off at 3300 VA
Underload Protection	Automatic shut-off at current below 100 mA
Thermal Protection	Automatic shut-off at internal temperature of + 85° C
Dimensions	350 mm x 530 mm x 320 mm
Weight	25.0 kg.
Power Source	
Type	Motor flexibly coupled to alternator and installed on a frame with carrying handles.
Motor	Briggs and Stratton, four stroke, 8 H.P.
Alternator	Permanent magnet type, 800 Hz, three phase 230 V AC.
Output Power	3500 VA maximum
Dimensions	520 mm x 715 mm x 560 mm
Weight	72.5 kg.
Total System	
Shipping Weight	150 kg includes transmitter console, motor generator, connecting cables and re-usable wooden crates.

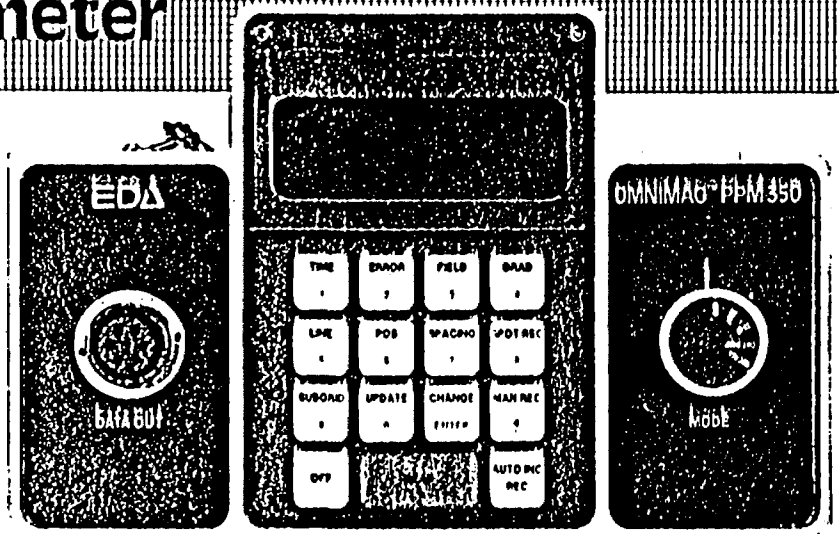
OMNIMAG PPM-350
Total Field Magnetometer

EDA



The PPM-350 is the latest addition to EDA's OMNIMAG*™ series of magnetometers and gradiometers. It is engineered to provide users with the latest state-of-the-art advances in microprocessor technology, including many features that are unique in the field.

Major benefits and features include:

- Significant increase in productivity
- Lowered survey costs
- Automatic diurnal correction
- Programmable grid coordinates
- Highly reproduceable data
- Ergonomic design
- Simplified fieldwork
- Computer-compatible

EDA

Specifications

Dynamic Range	18,000 to 93,000 gammas
Sensitivity	±0.02 gamma
Statistical Error Resolution	0.01 gamma
Standard Memory Capacity	1383 data blocks or readings
Absolute Accuracy	±15 ppm at 23°C, 50 ppm over the operating temperature range
Display Resolution	0.1 gamma
Capture Range	±25% relative to ambient field strength of last stored value
Display	Custom-designed, ruggedized liquid crystal display with an operating temperature range from −35°C to +55°C
Gradient Tolerance	5,000 gammas per meter
Sensor	Optimized miniature design. Magnetic cleanliness is consistent with the specified absolute accuracy
Sensor Cable	Remains flexible in temperature range; includes low strain connector
Operating Environmental Range	−35°C to +55°C; 0–100% relative humidity; weather-proof
Power Supply	Non-magnetic rechargeable sealed lead acid battery cartridge or belt; or, Disposable "C" cell battery cartridge or belt
Battery Cartridge Life	2,000 to 5,000 readings, depending upon ambient temperature and rate of readings
Weight and Dimensions	
Instrument Console only	3.4 kg, 238 x 150 x 250 mm
Lead Acid Battery Cartridge	1.9 kg
Sensor	1.2 kg, 56 mm diameter x 200 mm
System Complement	Electronics console; sensor with 3-meter cable; sensor staff; power supply; harness assembly; operation manual.

EDA is a pioneer in the development of advanced geophysical systems and has created many innovations that increase field productivity and lower survey costs.

EDA's OMNIMAG series consists of the PPM-350 Total Field Magnetometer, PPM-400 Base Station Magnetometer, and the PPM-500 Vertical Gradiometer. Contact us *now* for details.

Dear Sir/Madam:

Re: Notice of Intent dated June 21, 1990 for Magnetometer Survey submitted on Mining Claims P 1035690 et al in Keith Township.

No assessment work credits will be approved for this report as of the above date.

Please inform the recorded holder of these mining claims and so indicate on your records.

Yours sincerely,

W. R. Cowan

LATE INTRUSIVE ROCKS

8 [8] Proterozoic diabase

7 [7] EARLY FELSIC INTRUSIVE ROCKS

- 7a granitic rocks
- 7b quartz-feldspar porhyry

6 [6] EARLY MAFIC AND INTERMEDIATE INTRUSIVE ROCKS

- 6a gabbro
- 6b pyroxene porphyritic rock
- 6c diorite
- 6d feldspar porphyry

5 [5] ULTRAMAFIC ROCKS

- 5a peridotite
- 5b serpentinized peridotite
- 5c komatiite rock
- 5d carbonatized ultramafic rock

4 [4] SEDIMENTARY ROCKS

- 4a argillite
- 4b wacke (siltstone, sandstone)
- 4c conglomerate
- 4d chert
- 4e iron formation
- 4f graphitic rock

3 [3] FELSIC VOLCANIC ROCKS

- 3a massive flow or undifferentiated
- 3b flow breccia
- 3c porphyritic flow
- 3d tuff, crystal tuff
- 3e lapilli tuff

2 [2] INTERMEDIATE VOLCANIC ROCKS

- 2a massive flow or undifferentiated
- 2b pillow flow
- 2c pillow or flow breccia
- 2d amygdaloidal
- 2e porphyritic
- 2f tuff, crystal tuff
- 2g lapilli tuff
- 2h agglomerate
- 2j reworked tuff (tuffacous sedimentary rock)

1 [1] MAFIC VOLCANIC ROCKS

- 1a massive pillow or undifferentiated
- 1b pillowed flow
- 1c pillow or flow breccia
- 1d amygdaloidal
- 1e variolitic
- 1f porphyritic
- 1g pyroclastic

Rock Types as per Whole Rock Analysis (XRAL)

- FT Iron Rich Basalt
- AT Tholeiitic Andesite
- MT High Magnesium Basalt
- BT Tholeiitic Basalt
- BC Calc-Alkaline Basalt

SYMBOLS

- float
- drill hole
- sample location
- trench
- foliation with dip
- cleavage with dip
- lineation with plunge
- jointing with dip
- drag fold
- brecciation
- bedding with dip and tops direction
- pillow tops direction
- shearing
- x rock outcrops
- scarp
- vegetation boundary
- wet lowland
- creek.
- esker
- gravel road
- trail
- claim post and lines
- assumed post
- ▼ samples taken in 1989
