Lamport-Lumbers Property (2, 6)

One of the first gold showings discovered in the map-area is located within a group of five patented claims, P4803 to P4805, P4807 to P4810, situated on the western boundary of Sewell Township, about 3,000 feet south of Highway 101. These claims were owned, in 1967, by N.W. Lamport and J. Lumbers.

The claims are part of a group of six known originally as the Gosselin Claims and described by E.W. Todd (1924, p.14-15) as follows:

... They were originally staked by ... [D.] Arkell. Gold was found in a quartz vein on one of these claims in 1916 by T.L. Tanton, who reports an assay of 0.02 ounces per ton from a sample taken across the vein.

The rocks in this neighbourhood are chlorite carbonate schists resulting from the alteration of Keewatin volcanic and intrusive rocks, principally basalt, andesite, and diabase. A prominent ridge of fresh diabase intrudes the schists on claim 4808.

Extending north and south across claims 4810, 4807, and 4805 is a well-defined faulted zone which is largely filled with irregular masses of quartz. The vein material mixed with country rock in places reaches a width of fifty feet. Associated with the quartz are pyrite, pyrrhotite, chalcopyrite, calcite, tourmaline, and mariposite, a chrome mica.

The rocks enclosing the quartz are liberally impregnated with sulphides, resulting in the development of much iron oxide in proximity to the fault. No porphyry is observed in the area shown on the sketch map, but one-half mile to the south a number of dikes of fresh feldspar porphyry intrude the Keewatin rocks. These dikes are probably of Algomian age. [These dikes were not found by Milne.]

Some surface work has been done on the deposits: the vein has been cleared and stripped for a distance of half a mile, and three pits have been sunk to a depth of about eight feet. [Pits were not found by Milne.]

The rocks within the claim area are pillowed mafic flows intruded by a 150-foot wide diabase dike. Strong shearing has converted the flow rocks to dark green, rusty weathering, chlorite-carbonate schist. Much of the rusty iron oxide weathering is due to alteration of the carbonate, which is sideritic, and this ferruginous carbonate usually occurs as brown, 1/8 inch, rhombohedral porphyroblasts in the dark green chlorite schist.

There is no record of any further work on these claims and the stripping and trenching is now overgrown.

Dear Sir or Madam

Subject: Deemed Approval of Assessment Work

We have approved your Assessment Work Submission with the above noted Transaction Number(s) as per 6(7) of the Assessment Work Regulation. Only eligible assessment work is deemed approved for assessment work credit. The attached Work Report Summary indicates the results of the approval.

NOTE: The report has not been reviewed for technical deficiencies and reported expenses were not evaluated based on the Industry Standard.

At the discretion of the Ministry, the assessment work performed on the mining lands noted in this work report may be subject to inspection and/or investigation at any time.

If you have any question regarding this correspondence, please contact BRUCE GATES by email at bruce.gates@ndm.gov.on.ca or by phone at (705) 670-5856.

Yours Sincerely,

Ron Gashinski
