## EXECUTIVE SUMMARY

In April 1997, Golden Goose Resources Inc. drilled ten holes totalling 2087.5 m on its Magino Mine property in Finan Township, Ontario. These holes were drilled on three fences of three holes each with one further hole on another section. The fences were aligned along section lines corresponding to the mine grid used by previous operators.

The objectives of the program included:

- Verifying the potential of the mine area to host a large tonnage of low grade gold mineralization amenable to open pit mining.
- Determining the distribution and nature of high grade (multi-gram) gold mineralization relative to more pervasive low grade gold mineralization.
- Twinning of previously drilled surface holes to determine the repeatability of former drill hole results.
- Establishment of sample protocol for future drill programs.

The results of the program confirmed the presence of long intervals of low grade gold mineralization within the host Webb Lake Granodiorite. Within these intervals there are often short intervals of high grade gold mineralization associated with narrow (mm-cm width) quartz stringers. Minor pyrite and sericite is associated with these veins. The nature of these veins is similar to a stockwork with <5% quartz overall. In addition to mineralization within the granodiorite, low grade mineralization also occurs in the host volcanic rocks.

The grain size of the gold particles is quite fine and they often appear in closely-spaced clusters or clouds. There was excellent repeatability between various fractions of sub-samples as determined by check assaying. However, resampling the archived half of split core, and the results of the twin holes demonstrate that there is extreme variability in grade over short distances. Thus, despite the fine grain size of the gold particles, the distribution of the gold is very erratic and local grade estimation is therefore problematic.

The 1997 drill program confirmed the potential of the property to host low grade mineralization that could be mined by means of a large open pit. The fine grain size of gold, even where grades are high, allows fairly good accuracy in the analytical stage. However, the erratic nature of the gold makes local grade estimation somewhat uncertain.

## 1.0 INTRODUCTION

In April 1997, Pearson, Hofman and Associates Ltd. (PHA) supervised a ten hole diamond drill program on behalf of Golden Goose Resources Inc. (GGR) at the Magino Mine property in Finan Township, Ontario. This drill program was a component of a larger overall study managed by PHA to evaluate the potential of the property for a large open pit mining operation centred on the area containing former underground workings.

Over 1,200 surface and underground diamond drill holes had previously tested the mineralization in the vicinity of the mine as part of prior surface exploration and underground definition drilling campaigns. The objective of the April 1997 program was to verify the nature of the overall geology and, more specifically, to evaluate the character of low grade mineralization that might be amenable to a high tonnage open pit operation. This involved both cross-sectional drilling of the primary host rock, the Webb Lake Granodiorite, and twinning of previous surface holes drilled in the mid to late 1980's. A thorough QC/QA protocol was implemented with fire assaying done by an independent laboratory and check assaying done by a second independent laboratory.

All the historic data and mine grid are in imperial units, therefore this report quotes units in imperial measure with metric conversions included where appropriate.

### 1.1 LOCATION, ACCESS AND PHYSIOGRAPHY

The Magino property is located in the southern half of Finan Township about 50 km northeast of the town of Wawa, Ontario (NTS 42 C/8). Access is via an 18 km all-weather gravel road that turns off Highway 519 just west of the town of Dubreuilville (Figure 1). Dubreuilville is on Highway 519, 44 km east of the junction of Highways 17 and 519. That junction is in turn about 40 km north of Wawa on Highway 17.

A 44 kv power line and a gravel road extends from Goudreau about 7 km west of the property, through the minesite, to Lochalsh about 14 km east of the mine. Goudreau is a siding on the Algoma Central Railway and Lochalsh is a siding on the Canadian Pacific Railway.

The topography in the area is characterized by low ridges and hills, of up to 50 metres relief, flanked by generally flat areas of glacial outwash, swamps and numerous lakes.

2 • 1 77 64

## 1.2 LAND STATUS

The property consists of 80 claims all within the south half of Finan Township, Sault Saint Marie Mining district, Province of Ontario (Figure 2). The claims consist of patented, leased and staked claims as listed in Table 1. The claims are contiguous, wholly-owned by Golden Goose Resources Inc. (Ministry of Northern Development and Mines, Client #174165) and at the time of writing are all in good standing.

## 1.3 PROPERTY HISTORY

Gold was discovered on the Magino Mine property by prospecting in 1917. The mine area was staked and in 1925 shares in the McCarthy Webb Company were offered to the public to assist in developing the property. In 1931, a new company Algoma Summit Gold Mines was formed and an inclined shaft was sunk to the 100 foot level. Over 116,000 tons were mined intermittently through the 1930's and 8,700 ounces of gold were recovered by 1939 when mining operations were suspended. In 1940, Magino Gold Mines was formed. Drifting and diamond drilling were completed but work ceased due to a lack of funding and wartime shortages. Other than some surface drilling completed in 1942, no further work was done until 1962 when Mr. C. McNellen completed 6 diamond drill holes that intersected gold values beneath the mine workings. In 1981, Rico Copper (1966) Ltd., which later became McNellen Resources Inc., drilled 16 holes. In 1981, McNellen Resources Inc. and Cavendish Investing Ltd. formed a

joint venture to pump out the old mine workings, and completed underground mapping, sampling and drilling. Muscocho Explorations Ltd. acquired the Cavendish Investing Ltd. interest in the mine in 1985.

In 1985 and early 1986 Muscocho Explorations Ltd., in joint venture with McNellen Resources Inc., drilled 29 surface holes which, along with previous work, indicated a reserve of 1.9 million tons at 0.25 oz/ton Au. A ramp was started in 1986 and developed levels at the 100 and 200 foot elevations (below and adjacent to the old workings). Mining and the construction of a 400 tpd mill started in 1987, and the first gold bar was poured in June 1988. From 1988-1992, the Magino Mine processed 768,678 tons at a recovered grade of 0.137 oz/ton Au to produce 105,543 ounces Au (697,222 tonnes @ 4.71 g/t Au). From 1988 to sometime in 1989, mining was principally accomplished by shrinkage stoping which produced an average grade of ~0.2 oz/ton Au. In 1989 mill throughput was increased to 640 tpd and production was chiefly from longhole stopes at an average grade of 0.12 oz/ton Au. The reduced mining cost for the longhole stopes was offset by substantial dilution with a resultant increase in the cost per ounce mined. In mid 1992, the mine closed due to high operating costs and the underground workings were allowed to flood. The site has been on a care and maintenance footing since then.

In 1996, Golden Goose Resources Inc. obtained the Magino Mine property through an amalgamation of Muscocho Explorations Ltd., Flanagan McAdam Resources Inc. and McNellen Resources Inc.

#### 1.4 GEOLOGY

The property is located in the Michipicoten greenstone belt of the Wawa subprovince within the Superior geologic province. Felsic volcanic rocks occur just to the south of the property and mafic volcanic rocks occur throughout and to the north of the property (Figure 3). A thin but extensive pyrite-rich iron formation, known as the Goudreau Iron Range, occurs close to or on the contact between the felsic and mafic volcanics.

The volcanic rocks trend between 070° and 090° in the immediate property area. Locally they have been tightly folded. Intrusive rocks found on the property include granitic rocks, from tens of metres up to several kilometres in size, and a large stock of nepheline syenite that occupies the north part of the claim block. The principal ore host for the Magino Mine is the Webb Lake Granodiorite (WLG) which occurs near the southern part of the property and appears to intrude along, and partially cut across, the mafic/felsic contact.

The WLG is a felsic, porphyritic intrusive that is elongate in shape with dimensions of about 2,000 metres by 200 metres in plan, with the long axis striking about 070°. It is open to depth and, according to some reports, becomes

wider. Contacts are sharp and dip vertically to steeply to the north. The composition of the intrusive is somewhat variable and was subdivided according to modal mineralogy by Muscocho geologists. Whether that variation is due to primary lithological variations in phases of the intrusion, regional metamorphism, hydrothermal alteration or a combination is not clear. The mineralogy is primarily quartz (40-50%), plagioclase (25-35%), chlorite (10%), and sericite (10%) (Sutherland, 1987). This unit has been variably classified as a quartz-feldspar porphyry, granodiorite and trondhjemite (Heather & Arias, 1992) but the long-standing use of the term granodiorite by property geologists is most convenient. Locally, hydrothermal alteration results in feldspar destruction and the development of pervasive sericite.

Felsic and mafic dykes are found within the WLG and appear to correlate from section to section. They are interpreted to predate the gold mineralization but their temporal and genetic relationship to gold mineralization is not clear. Until this relationship is determined, they cannot be considered "stratigraphic markers" as they have not been shown to relate to either volcanic stratigraphy or to mineralized zones in the granodiorite.

A 15 metre wide diabase dyke trending about 335° (Mine Diabase) cuts the granodiorite and separates the Northeast Zone of the mine from the Main Zone. This dyke is thought to occupy the plane of an earlier fault that has had sinistral displacement along it. However, the horizontal distance between mineralized zones across this structure exceeds that shown for the displacement of the boundaries of the granodiorite on mine plans. This suggests that if the displacement entirely post-dates mineralization, it must be oblique or, alternatively, the zones on either side of the diabase are not related.

Mineralization is found in all lithologies except the diabase. Significant economic mineralization discovered to date is restricted to the eastern end of the WLG. Within this area, the northern and southern margins are host to gold mineralization principally within a sub-unit designated as Unit 2 (Network Granodiorite) which is slightly more sericitic and more altered than the core of the intrusive (designated Unit 2V, Speckled Granodiorite). The mafic minerals in Unit 2 comprise from 7-20% of the rock and form a network texture around the quartz and plagioclase, whereas in Unit 2V, mafic minerals comprise less than 7% of the rock. Other minor phases of granodiorite are also present (Deevy, 1992).

The 2V unit is considered, in most recent reports, to be a separate, poorly mineralized phase of the intrusion but level plans clearly demonstrate that it also hosts gold mineralization.

A detailed geology legend describing rock types, alteration and structural features, established while the mine was operational, is included as Appendix IV. This legend was followed during the course of the current drill program.

## 2.0 APRIL 1997 DRILL PROGRAM

### 2.1 OBJECTIVES

There were several objectives for the April 1997 drill program. First, to confirm the nature and character of the granodiorite and its associated gold mineralization. In particular, an assessment was needed of the distribution of high and low grade mineralization across the width and along the length of the mineralized part of the granodiorite as it might relate to a potential low grade, open pit operation.

Secondly, the new drilling was used to determine sampling and assay protocols for any future work. A component of the program also involved twinning previous surface holes to allow statistical evaluation of current results with those from earlier surface drilling. This component has added significance given the difficulty Muscocho Explorations Ltd. had in reconciling diamond drill results to production.

### 2.2 DRILL PROGRAM

A total of ten holes totalling 2,087.5 metres were drilled during the period April 1 to April 25, 1997 by Chibougamau Diamond Drilling Ltd. of Chibougamau, Quebec. All holes were drilled from north to south (azimuth 180°), on cut grid lines turned off a surveyed base line that was established in late 1996. All core recovered was NQ in diameter. A Van Ruth plug was inserted in bedrock below the bottom of the casing and the top of the hole subsequently cemented. The casing was left in all holes.

A series of three north-south fences consisting of three holes each were drilled on widely-spaced sections. The fences were intended to be drilled such that a continuous section was completed from the volcanics north of the WLG, through the intrusive and out into the volcanics to the south. The fences were separated by 600 foot (183 m) intervals and aligned with the imperial mine grid established by the previous operators. Geologically, the eastern extent of the mineralized granodiorite, the central part of the mine and the west-central part of the mine were tested. A tenth hole was drilled into the west-central part of the mine as one of the fences could not be successfully completed due to mine excavations.

The location of the drilled sections and the drill holes relative to the mine workings is shown on Figure 4. Table 2 lists the location of the holes using the Magino Mine Grid.

**Table 2**

### **2.3 LOGGING, SAMPLING AND ASSAY PROCEDURES**

All drill core was washed and logged on site. The core is stored in wooden trays in permanent steel core racks on the property. Aluminium tags identifying the hole and footage were affixed to each box.

Geological units and features are described on drill logs and the RQD for each box is recorded. When logging, separate columns on the logs were established for each sample interval for Pyrite %, Quartz Vein %, Quartz Vein to Core Axis Angle, Alteration, and Other Mineralization. As the drill contractor used a metric core barrel, all holes were logged and sampled using the metric system with conversion to imperial measure facilitated by computer after input.

Samples were taken at nominal one metre intervals with continuous sampling in the granodiorite and discontinuous sampling in the volcanics. The sample length was modified where a geological contact was crossed or where visible gold was noted.

In cases where visible gold was seen, a 0.5 metre sample length was used. For holes S97-01 to S97-03 inclusive, the entire core was submitted for visible gold samples. For the remainder of the holes, the sample intervals where visible gold was noted was sawn. In these cases, no preference given to which part of the core was submitted for assay. Instead, as with the balance of the samples, the core was oriented and cut using the "V" defined by the foliation in the rock. The half of the core not submitted for assay remains archived in the core boxes and the sample intervals are marked by tags.

All samples were shipped to Swastika Laboratories Ltd. in Swastika, Ontario. At Swastika, the entire sample was crushed to approximately 60% passing 20

mesh. A  $\pm 350$  gram portion of this was then split out and pulverized to approximately 80% passing 150 mesh. From this pulp, a one assay ton aliquot was fire assayed. If the resultant bead was large enough, the grade of the sample was determined gravimetrically. If the bead was fairly small (equivalent to ~1,500 ppb or less), it was dissolved and the grade determined by means of atomic absorption analysis. For those samples with visible gold, the pulp and metallic method of assaying was used.

A check assay of the original pulp was systematically done for every tenth sample. In addition, a second pulp was prepared from the coarse reject fraction for every tenth sample. Blanks of diabase dyke were inserted randomly at the minesite. Internal checks of standards and blanks prepared by Swastika were also reported.

Subsequent to the completion of the program, approximately 5% of the pulps analyzed by Swastika were sent to Chemex for check assaying. Again, a one assay ton fire assay procedure was used by Chemex.

### 3.0 RESULTS

#### 3.1 GEOLOGY

The overall nature and geometry of the major rock types correlated well with that recorded in the Muscocho Explorations Ltd. database. All the principal lithologies were intersected in the 1997 holes and, as part of separate metallurgical testing, representative pieces of granodiorite, carbonate facies iron formation, mafic volcanics, intermediate to mafic tuff and felsite dyke were sent to Lakefield Research Ltd. for specific gravity determinations.

It is apparent that the current rock code subdivides the granodiorite according to a combination of primary mineralogical features (i.e. per cent chlorite), structural features (intensity of foliation), and alteration (sericite, carbonatization, etc.). In fact, an argument might be made that there is a correlation between colour index (chlorite content), the amount of sericite and the degree of apparent foliation. Nevertheless, the large number of past drill holes logged in this manner makes a modification of the code for a few new holes unrealistic. The inclusion of individual columns for alteration, intensity of foliation and lithology, on an individual sample basis, as was done with the April 1997 drilling, appears to be the best way to document the various parameters while still using the existing rock code for longer intervals. The contacts between these longer intervals are typically gradational and arbitrary.

The variation in sulphide mineralogy associated with gold between the holes east and west of the diabase dyke, as noted by Deevy (1992), was verified in the 1997 drilling. The presence of molybdenite and chalcopyrite with the gold mineralization suggests that:

- the eastern part of the granodiorite appears to have mineralization more typical of a porphyry-style hydrothermal system with molybdenite and chalcopyrite common in quartz veins;
- this moly-cpy-gold mineralization may have formed at different (likely deeper) P-T conditions. If in fact this association represents a deeper mineralized environment, then the likelihood of similar mineralization existing below the main part of the mine is good. Also the prospect of finding mineralization along lateral conduits from the deeper environment should be assessed.

The best way to determine the exact variation, and hence genetic differences, between the two styles of mineralization would be through thin section and fluid inclusion studies. In terms of alteration, lithological textures or vein character, there does not seem to be much difference between the mineralized intervals in the eastern part of the granodiorite and the mineralized granodiorite seen elsewhere.

### 3.2 ASSAY RESULTS

#### ***Overall Distribution of Gold Mineralization***

All the 1997 drill holes intercepted high grade gold mineralization over narrow widths, typically as visible gold associated with narrow (5 mm to 10 cm) quartz veins and minor amounts of accessory pyrite and sericite. There are often fine bands of tourmaline associated with the auriferous veins and, in the holes on Section 40E, occasionally chalcopyrite and/or molybdenite. Some auriferous quartz veins do not have any significant amounts of tourmaline or accessory sulphide minerals with them.

Not only was gold mineralization present in all holes and on all the sections drilled, there were several occurrences of mineralization in most holes. A total of 1971 samples were submitted for assay. Of these, 53 returned values greater than 5.0 g/t Au.

#### ***Gold Distribution by Rock Type***

Table 3 lists the distribution of assays by grade range for all rock types and for granodiorite alone. Gold mineralization at Magino is documented in most reports as being better within the granodiorite than in other rock types. The data from Table 3 implies that the distribution of gold in other rock types may not be that much different than that of the granodiorite.

**Table 3**  
**FREQUENCY OF GOLD INTERCEPTS BY ROCK TYPE**

CLASS Assays in g/t	FREQUENCY Granodiorite	FREQUENCY All Rock Types	FREQUENCY as % Granodiorite/All Rocks
All Assays	1658	1971	84%
> 0.1	892	990	90%
> 0.5	331	373	89%
> 1.0	171	196	87%
> 5.0	49	53	92%
> 10.0	23	26	88%
> 30.0	5	6	83%

### ***Spatial Variation of Gold Mineralization***

The length-weighted average grade of the granodiorite varies on a section by section basis as outlined in Table 4. Also presented in Table 4 is the length-weighted grade of each rock type. This data demonstrates that there is a spatial variation in the grade of the granodiorite as well as providing evidence that other rock types host low grade gold mineralization. The variation in grade on an individual section basis reflects the overall trend of the central part of the granodiorite (Sections 20E to 36E) to be somewhat better mineralized than the peripheral areas.

**Table 4**  
**VARIATION OF GOLD GRADE BY SECTION**

<b>Length-Weighted Average Grades</b>	<b>Length (m)</b>	<b>Grade Au g/t</b>
<b><i>Granodiorite Only</i></b>		
Section 40E	555.6	<b>0.38</b>

### **Association of Gold with Foliation, Alteration, Quartz or Pyrite**

Pyrite content, quartz vein percentage and an alteration/structural code were explicitly recorded for each sample taken. The alteration/structural code is described under the geology section of this report and listed in Appendix IV.

On a hand specimen scale, veins with visible gold often can be seen to have somewhat more sericitic vein margins with pyrite developed both along the vein margin and disseminated in the wall rock adjacent to the vein. Table 6 lists the arithmetic average grade of each class of alteration as recorded in this drill program. In many instances, more than one alteration code was listed for an individual sample. For these samples the first code listed was used.

**Table 6**  
**ASSOCIATION OF GOLD WITH ALTERATION**

ALTERATION CODE	CODE DESCRIPTION	AVERAGE GRADE g/t (ARITHMETIC)	FREQUENCY
A*	Weakly Foliated	<b>1.04</b>	607
B*	Strongly Foliated	0.11	27
C*	Moderately Foliated	0.31	137

K	Chlorite	<b>0.62</b>	149

\*Structural Codes

The structural features or alteration assemblages for which the gold grade averages are above the mean grade of the granodiorite (0.58 g/t Au) are weakly-foliated rock, and those with either hematite, silica, carbonate, sericite or chlorite alteration. The association of lower than average grade material with moderately or strongly foliated rock suggests that the brittle fracturing needed for the emplacement of auriferous veins may not necessarily be accompanied by intense ductile deformation.

#### ***Association of Gold with Pyrite and Quartz***

On the scale of sampling (one metre intervals), there is almost no correlation of gold with pyrite content (coefficient of correlation = 0.07) and only a very poor correlation with quartz vein content (coefficient of correlation = 0.17). For pyrite, this is attributed to the very low overall pyrite content, particularly in cases where elevated pyrite related to a narrow stringer is averaged over one metre.

There is a weak positive correlation between gold mineralization and percentage quartz. The presence of visible gold in stringers that are typically from 0.5 to 5 cm in width results in the correlation that occurs on a small scale being lost on the metre scale. The presence of low grade or entirely non-mineralized quartz veins also influences this relationship. It appears as if, on the scale of drill core logging and for drillhole analysis, both pyrite and quartz content are only approximate indicators of gold tenor. Specifically, while gold is generally found in association with pyrite and quartz, there are many instances of elevated pyrite content and/or quartz veining with no associated gold mineralization.

### **Coarse Gold and the Nugget Effect**

Where visible gold was noted, the samples were analysed using the pulp and metallic method. Analysis of the amount of gold in the pulp fraction (-100 mesh), versus the amount of gold in the metallic fraction (+100 mesh), indicates that for the *majority* of visible gold occurrences in this program, the gold occurred as fine particles distributed almost entirely in the pulp fraction with only a few samples having any gold in the coarse or metallic fraction. Consequently, the variation in gold grade introduced by subsampling within a finely pulverized pulp should not be significant. Thus the nugget effect, *defined as coarse gold particles greater than 1.0 mm in size*, is not as great a factor for the Magino property as it is for many other Archean gold deposits.

### **Check Assays**

A further measure of variation in gold grade introduced by sampling is the difference in grade between the original assay and that of either check assays of the same pulp (inter-pulp), or, check assays done on another pulp made from the coarse reject fraction of that sample (intra-pulp). For the April 1997 drill program, 5% of the original pulps were systematically checked by Swastika Laboratory while being assayed, and 5% of the coarse rejects were similarly checked.

The inter-pulp checks have a coefficient of correlation of 0.997 (Figure 5). Except for those close to the lower detection limit, all the checks ( $n=290$ ) fall within  $\pm 20\%$  of the original assay value.

The coefficient of correlation is 0.943 for the intra-pulp checks ( $n=203$ , Figure 6), with 5 of the original samples above 2.5 g/t falling outside the  $\pm 20\%$  limit. For one of these, the original pulp assayed 18.86 g/t and the reject fraction assayed 3.94 g/t. This sample, at 210 m in hole S97-05, had minor quartz and tourmaline plus 2% pyrite noted but no visible gold. It seems probable that there was in fact some coarse gold in the sample and that the gold was not distributed evenly between the coarse reject and pulp fraction when the original pulp was split out.

### **Independent Check of Laboratory**

A total of 87 pulps were sent to Chemex Labs Ltd. of Mississauga for comparison with Swastika's results, including 11 blanks. The coefficient of correlation between the 76 matching samples is 0.995. Figures 7a and 7b show this comparison as a scatter plot. None of the blanks returned detectable gold when assayed by Chemex.

### 3.3 RECONCILIATION BETWEEN SPLIT CORE AND TWINNED HOLES

#### *Split Core*

The archived half of the sawn core from hole S-97-08 was sent for assay to determine the variation in gold distribution caused by splitting the core. The length-weighted grade of the original half is 0.26 g/t, and the length-weighted grade of the archived half is 0.28 g/t. The coefficient of correlation between these two halves is 0.85. While the mean grade is close, the conclusion to be drawn is that subsampling, even on the scale of NQ core, introduces a certain amount of variation to results (Figure 8).

The archived half of hole S-87-043 was also resampled. This hole is also a twin to S-97-08 (see below). The original length-weighted grade for this hole, on the basis of Muscocho assays, was 0.61 g/t over 497 feet. The resampled core, as analyzed by GGR, returned 0.49 g/t over the same interval. The coefficient of correlation is 0.55 (Figure 9). The lower correlation might be attributable to core size, this hole being BQ rather than NQ. While these results may suggest that further check assaying of archived Muscocho core is warranted, the discrepancy is not too significant.

#### *Twin Holes*

Comparisons between holes in this program, to previously drilled surface holes that were plotted as being collared in approximately the same location, are shown in Table 7. The collars for the 1987 holes were not located in the field. Holes S-87-001 and S-97-07 were both collared near 34+00 N, 28+00 E. The average grade for these two holes is close (0.38 g/t and 0.32 g/t respectively).

Holes S-87-043 and S-97-08 were both collared near 32+00 N, 28+00 E. There is considerable variation between the grade of the original hole and the 1997 hole (0.61 and 0.23 g/t respectively). Although the grade of the 1997 twin averages less than half that of the 1987 hole, check assaying of the archived halves of both holes indicates that the difference is not caused by sampling or analytical error. Instead, the difference is attributed to the erratic nature of the gold distribution over short distances.

## 4.0 CONCLUSIONS

The 1997 drill program confirmed the nature of the mineralization at Magino and demonstrated that low grade (0.5 g/t and higher) mineralization, that might be exploited by means of an open pit, occurs throughout the previously mined areas. Narrow quartz stringers with minor pyrite host higher grade gold mineralization. About 50% of the sampled core returned assays >0.1 g/t and 10% averaged 1.0 g/t or better. Although most of the drilling was in granodiorite, significant gold mineralization was found in all rock types. The length-weighted grade of all the granodiorite drilled was 0.58 g/t. Selected continuous intervals of 10 m or more, within the granodiorite, averaged 1.85 g/t (1.69 g/t cut to 34.2 g/t) over a cumulative length-weighted interval of 370 m. Many of these better grade intervals are comprised of a few high grade sections of several g/t over short lengths within much wider low grade intervals.

The fineness of gold particles encountered in most core samples at Magino, coupled with fairly fine grinding during the preparation of samples for assaying, resulted in there being relatively few, and generally small, variations in grade introduced by subsampling. With one exception, no significant problems due to coarse gold particles were encountered during the sample splitting or processing stages of the April 1997 drill program.

Reassaying of archived core suggests there may be some analytical or sampling errors in early surface holes drilled by Muscocho. Check assaying by GGR of the archived split core for Hole S-87-043 returned a length-weighted grade of 80% of the original value. Insufficient data is available to determine the extent and cause of this difference and whether the variation in grade is systematic or random. This discrepancy between resampled core is not as significant as the variation in grade between closely-spaced holes.

Two holes in the 1997 program were drilled close to the coordinates listed for the 1987 holes. The variation in grade between relatively closely-spaced drill holes can be substantial, and therefore, even if the gold particle size is not very coarse, the gold distribution over short distances is quite erratic.

## 5.0 RECOMMENDATIONS

- Continuous sampling of all core ought to be undertaken given that there seems to be only a slight variation in grade between the granodiorite and other rock types. The division of the granodiorite into sub-units seems to cause confusion rather than assist in the identification of mineralized rock. However, given the amount of historical data using this classification scheme, the lithology code is best left as is with structural and alteration modifiers appended to rock type.
- The fine particle size of the gold, even in instances where gold was seen, does not require that pulp and metallic assay procedures be used. However, as the additional cost of this procedure is small, it is probably worthwhile for future exploration programs. Sample preparation procedures should continue to use very fine crushing and pulverising steps to ensure the maximum homogeneity possible for subsamples.
- While the variation in grade between assays reported by Muscocho and those obtained by GGR for archived core is not great, this topic warrants additional study. In the event that the historical data forms the basis of an economic study, at least 5% of the archived surface and underground drill core should be resampled.
- There is a significant difference in grade between one of the 1987 drill holes and its 1997 twin. This is presumed to be due to the highly erratic distribution of gold. It is unlikely that drilling very large diameter holes will address this problem. However, core of at least NQ diameter should be used for all future drill programs.
- A geostatistical study should be undertaken to determine the most representative sample weight needed to ensure reproducibility of assay values. Existing sample rejects could be used for this purpose.
- If studies using the existing data show the open pit scenario to be feasible, drilling to identify additional low grade mineralization is warranted along strike of the known mineralization in the granodiorite. Step-out drilling on 100-200 foot (30-60 m) centres is recommended where low grade mineralization similar to that identified in the mine area is encountered. Closer spaced drilling would be required to delineate high grade shoots.

## 7.0 STATEMENTS OF QUALIFICATIONS

### 7.1 FREDERICK WILLIAM NIELSEN

I, Frederick William Nielsen of Lot 5 Concession 5, Erin Township, 9129, R.R. #2 Acton, Ontario, Canada L7J 2L6 do hereby certify that:

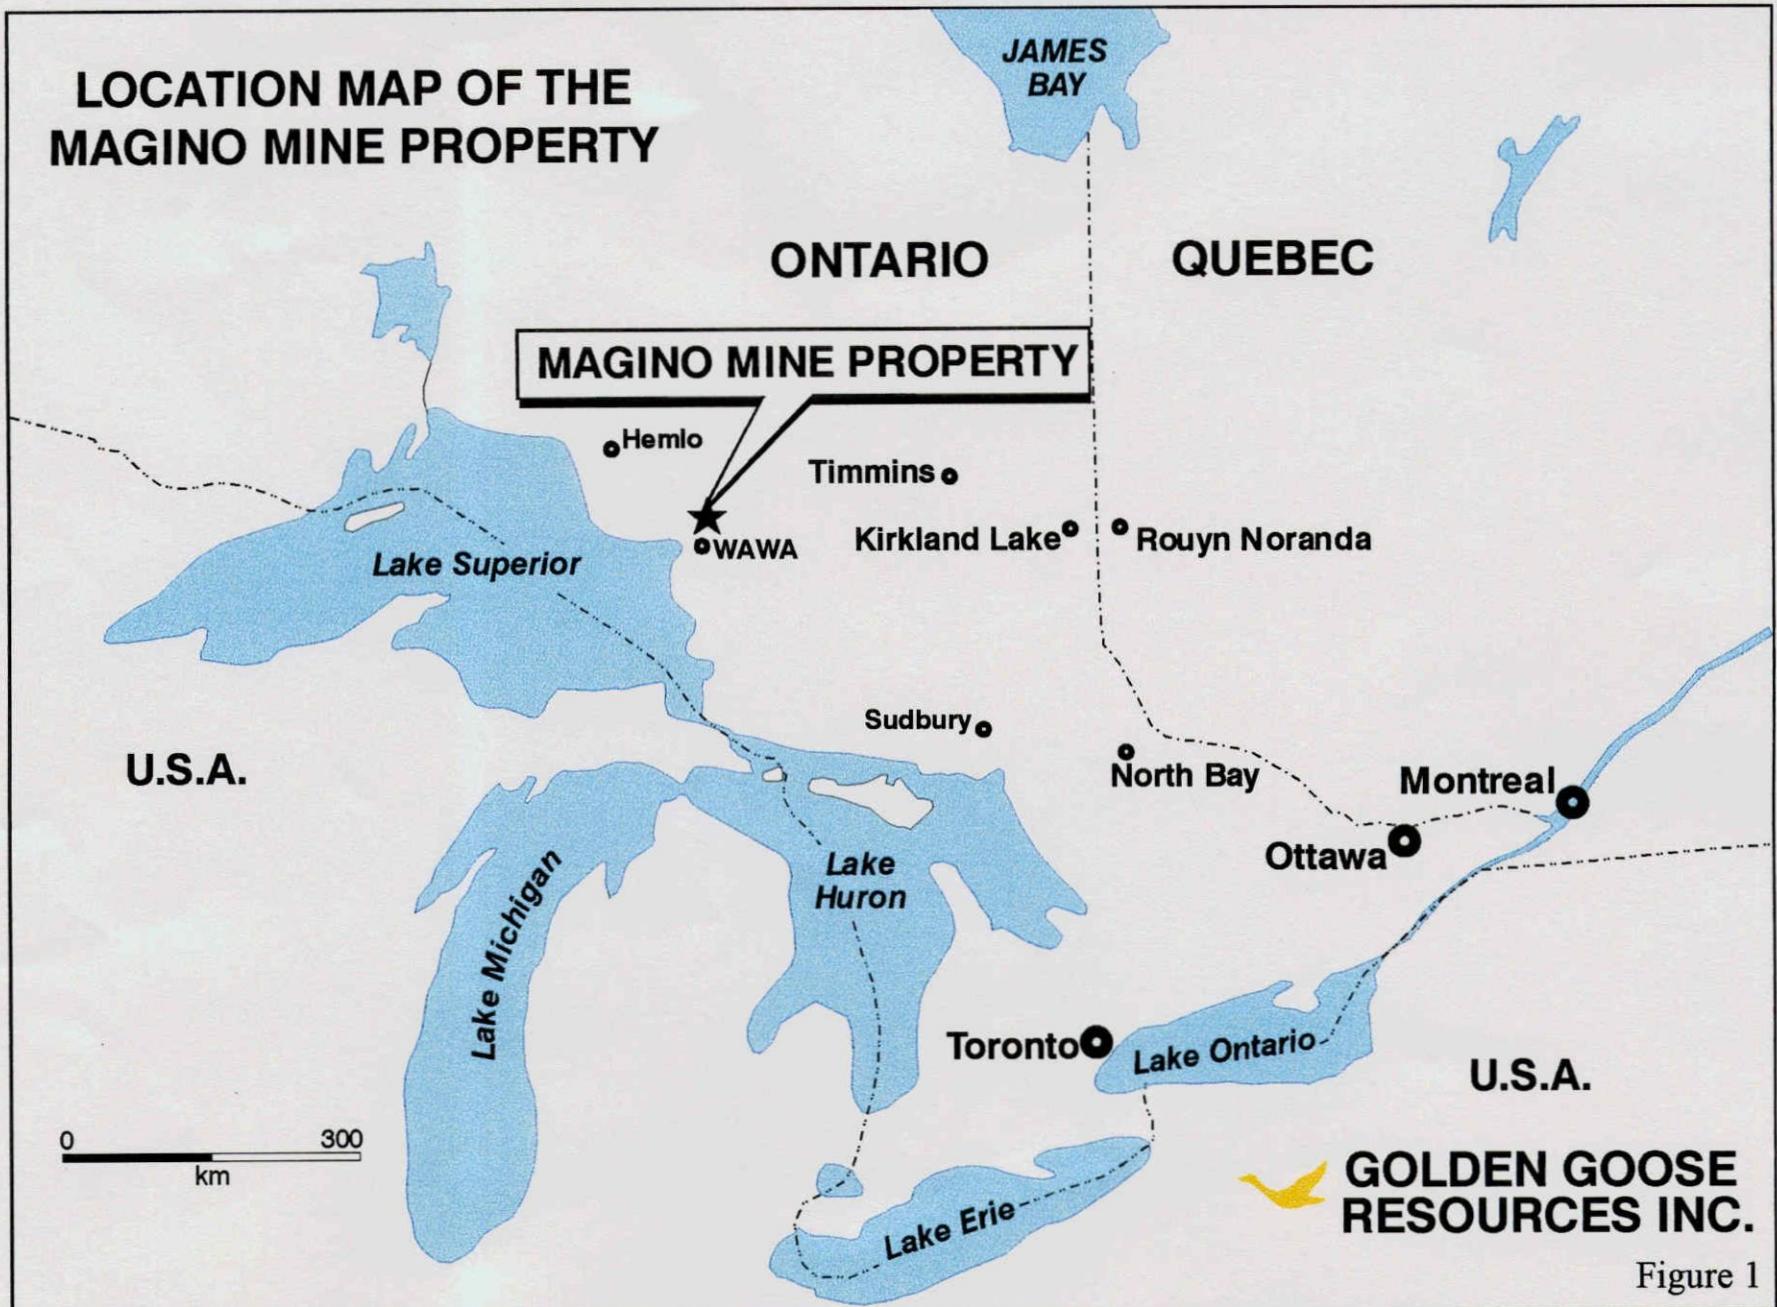

1. I am a consulting geologist retained by Pearson, Hofman and Associates Ltd.
2. I received a BASc degree in Geology from the University of Western Ontario, London, Ontario in 1973.
3. I am a Fellow of the Geological Association of Canada.
4. I have been practising my profession for over 23 years.
5. I have not received, nor do I expect to receive any interest, directly or indirectly, in Golden Goose Resources Inc. or any of its affiliates.
6. This report, as well as its conclusions and recommendations are based on the examination of available data.

Dated this 25 day of Sept, 1997.

  
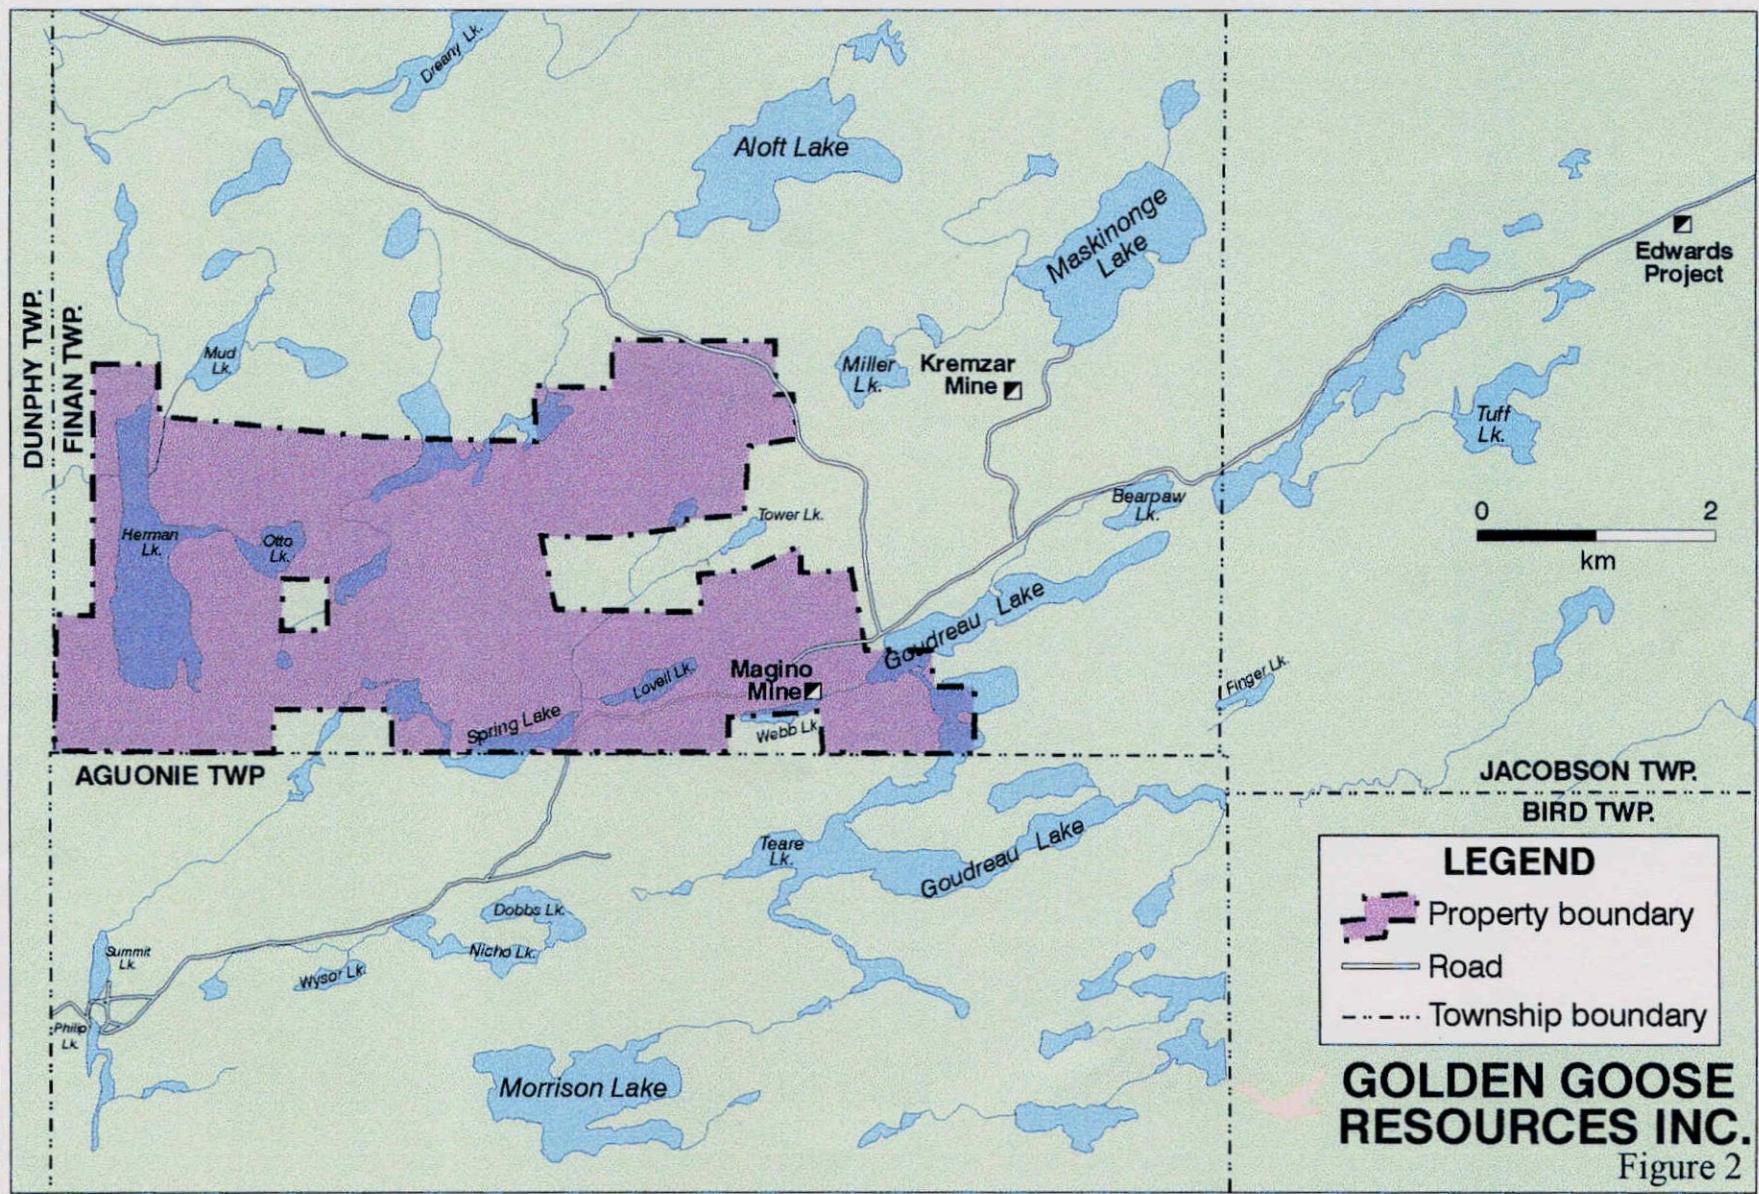

F. William Nielsen

578.63	605.64	2	<p><b>NETWORK GRANODIORITE</b>  Medium gray/green, massive, weak fol, composed of qtz-plaq-amph crystals gen 1-3mm size, anhedral blue qtz crystals common, minor &lt;0.5m zones of light granodiorite (2T) and sericite alteration up to 30% locally.  NOTE: GRANODIORITE: lithological differences are related primarily to grain size and sericite alteration eg 2P, 2, 2V, 2T are large grained/little ser alteration to fgr/intense ser alteration respectively. Foliation is then imprinted thus 2P-2A-2V-2T-2C-2B indicates a massive med grained granodiorite to a well foliated sericite schist progression. Thus supposed lithological changes are due to alteration then structure.  578.63 579.13 Qtz vein with Po and tourmaline.  589.56 589.89 Qtz vein, assimilative contacts, 55 degrees TCA.  600.71 610.23 Blocky core.  604.00 605.64 Light granodiorite-sericitized granodiorite.</p>	7141	580.70	583.98	3.28	.03		.03	.001

Mr. John Reddick  
Pearson, Hofman & Associates  
Box 579  
Porcupine, Ontario P0N 1C0

February 20, 1997

Dear Mr. Reddick;

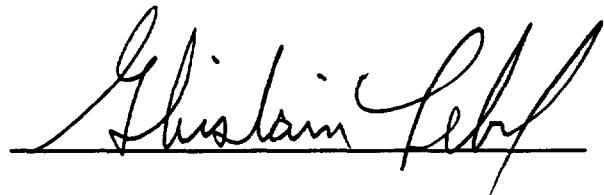

The following is a description of methods used to prepare and assay samples from your Magino GGR-8155 project.

- Sample preparation:** See "Routine Sample Preparation". The following steps are specific to your project.
- a maximum batch size of approximately 70 samples when entered onto the computer
  - dry and crush to 50% - 20 mesh
  - screen test on every 5<sup>th</sup>, 35<sup>th</sup> and 65<sup>th</sup> samples using 20 mesh screen and results are reported
  - riffle a 350g portion, pulverize and screen test every 5<sup>th</sup>, 35<sup>th</sup> and 65<sup>th</sup> samples using 150 mesh and results are reported
  - a second 350g pulp is prepared from every 10<sup>th</sup> sample as requested
  - remaining rejects are stored in plastic bags with the sample ticket showing, these are stored in large plastic sacks with a list of the contents showing through

- Gold Assay:** See "Gold by Fire Assay" for a general description. The following steps are specific to your project.
- a one assay ton sub-sample is used
  - one blank and two standards are included after every 27 samples, results are reported on these (control charts for standards are available)
  - 10% of the samples are assayed twice as part of our normal quality control, all values are reported

Results are faxed out as they become available with an original mailed to you upon completion of each group. The results are also available to you in electronic form, either by calling our Bulletin Board System or via a floppy disk with the contents formatted to your specifications.

Thank you,

A handwritten signature in black ink, appearing to read "Ghislain Lebel". The signature is fluid and cursive, with a horizontal line underneath it.

Ghislain Lebel

Assaying - Consulting - Representation

## ROUTINE SAMPLE PREPARATION

- 1) Dry samples if required.
- 2) Crush total sample to 1/2 inch (Jaw Crusher)
- 3) Crush total sample to 10 mesh (Rolls Crusher)
- 4) Split Approximately 350 grams using a Jones riffle.
- 5) The remaining reject is placed in a plastic bag, and packed in cartons with sample numbers listed on the outside.
- 6) Pulverize the 350g sample using a disc pulverizer. Ring mill pulverization is optional.
- 7) Homogenize the pulp, it is then ready for assay.

Sample preparation quality is assured by regular inspection, maintenance of crushing equipment, training and supervision of our staff to ensure that proper technique is utilized.

We prepare and analyze second pulps from stored rejects. The resulting data is compared with original results to verify sample sequence and also that repeatability is within acceptable limits.

To ensure that there is no dilution or concentration of various minerals, dust loss is kept at a minimum. For the critical pulverizing step, we have equipped our pulverizers with automatic draft shut off damper to eliminate sample pulp loss.

To prevent cross contamination, we use compressed air jets to clean the equipment between samples. The rolls crusher is cleaned using a wire brush combined with air jets. This system does a thorough cleaning. Also barren abrasive material is crushed between batches as an extra precaution.

## GOLD BY FIRE ASSAY ( General Description )

Both gold assay and geochemical gold analysis begin with a fusion using a flux mixture of litharge ( $PbO_2$ ), sodium carbonate, borax, silica, fluorspar with further oxidants (nitre) or reductants (flour) added as required. The relative concentrations of the fluxing materials are adjusted to suit the type of sample being analyzed. An aliquot of silver is added as a final collection agent. The resultant lead button containing the precious metals is reduced to  $PbO$ , and absorbed into a cupel in a cupellation furnace. The precious metals collected in the silver aliquot are now ready for either geochemical analysis using an atomic absorption spectrometer or a gravimetric assay finish. The geochemical method involves dissolving the precious metal and analyzing by atomic absorption. Gravimetric assays are completed by dissolving the silver of the dore bead in nitric acid and leaving the gold to be weighed on a micro balance.

If geochem beads are visually estimated to be 1500 ppb or more, we have the option of retrieving and weighing it. This option has been quite useful in getting the best of both methods.

Quality control consists of using inhouse or Canmet standards, blanks and by repeating at least 10% of the samples. All data is evaluated by the fire assay supervisor and additional checks may be run on anomalous values.

## **APPENDIX IV**

## **GEOLOGY LEGEND**

## MAGINO MINE COMPANY DESCRIPTIVE LEGEND

---

### **1 - Mafics**

Dark green in color, fine to medium grained, can be massive but usually foliated, composed of mainly plagioclase and chlorite. In foliated areas Qtz-Carbonate stringers are common.

### **1P - Porphyritic Mafics**

Compositionally and texturally similar to 1, except for 1/8" porphyritic plagioclase laths equally distributed throughout with no specific orientation.

### **2 - Network Granodiorite**

Medium green-grey color, uniform medium grained, composed of quartz, plagioclase and mafic minerals. The mafic minerals, amount to between 7% - 20% volume, are finer grained and create a network texture as they surround the medium grained Qtz and Feldspars. The Qtz is present as rounded eyes, usually white to clear in color, but blue eyes are common.

### **2V - Speckled Granodiorite**

Off white to medium grey sometimes slightly greenish in uniform medium grained but generally finer grained and fresher looking than '2' with speckled dark green mafic minerals. Plagioclase is more plentiful than quartz and these minerals account for most of the rock's composition. The mafic minerals speckle the rock and amount to 2-7% of overall composition. Where their percentage is higher they very often form rounded clusters.

### **2T - Light Granodiorite (Trondhjemite - Tonalite)**

Cream to beige colored rock, uniform to medium grained, composed of plagioclase and Qtz in a ratio of approximately 2:1. Mafic minerals can be present in an amount of 2% and somewhat speckle the rock. Quartz - Carbonate - Tourmaline veins are commonly present within this rock type.

### **2P - Porphyritic Granodiorite**

Dark to medium grey green rock, composed of Qtz and plagioclase and mafic minerals. The quartz is porphyritic with blue and white eyes 1/8" in size. Similar to 2, however network texture is lacking.

### **3R - Grey Felsite (Tectonized Granodiorite?)**

Grey color aphanitic (Very fine grained), hard and appears siliceous. A strong foliation is present with no noticeable phenocrysts. The contacts are also sharp. (Possibly tectonic rather than intrusive.)

### **3P - Pink Felsite (Qtz - Feldspar Porphyry)**

Pink to flesh tone color, aphanitic, hard and siliceous, occasional phenocrysts of Qtz and plagioclase. More distinctive is the apparent foliation which is actually flow

banding. The rock is composed of Qtz, plagioclase and some sericite. It is massive and the contacts are sharp. Chill margins are usually present.

#### **3Q - Brown Felsite (Qtz - Feldspar Porphyry)**

Light brown to reddish brown color, similar to 3P, aphanitic, hard and siliceous, 1/8" phenocrysts of quartz and plagioclase are common to abundant. Generally unfoliated. Composed of Qtz and plagioclase with sericite. The contacts are generally sharp and occasionally chill margins are present.

#### **4R - Diorite**

Medium pea leaf green, fine grained with small (1 mm) pheno-crysts of white plagioclase. Contacts are sharp and irregular.

#### **4T - Intermediate Tuff**

Medium grey color, often with a green tint; fine grained, medium hard, occasional small pyroclastic material distinguishable from the ash; banding apparent.

#### **4X - Intermediate Crystal Tuff**

Medium grey to medium green color, 1/8" rounded crystals of Qtz and plagioclase surrounded by matrix of fine grained material occasionally chloritic green in color. Contacts are usually sharp but are sometimes gradational into the mafics.

#### **5 - Diabase**

Dark green to black equigranular, fine grained rock composed mainly of plagioclase laths and acicular pyroxene crystals. A chill margin is usually present which is sometimes brecciated.

#### **60 - Oxide Facies Iron Formation**

Consists of bands up to an inch thick white chert and massive fine grained black magnetite/hematite.

#### **6S - Sulphide Facies Iron Formation**

Consists of massive to semi-massive amounts of Pyrite and pyrrhotite (occasionally chalcopyrite) along with varying amounts of the host rock (Volcanic mafics). Occasionally white cherty material or quartz is associated.

#### **6X - Carbonate Iron Formation**

Bands of off white to grey ankerite, siderite sometimes disseminated magnetite.

#### **7 - Sediments**

Generally grey to green grey thinly bedded generally fine grained greywacke.

#### **7Y - Carbonate Rock**

White to pale green thinly banded fine grained rock composed almost completely of fine grained calcite.

Personal information collected on this form is obtained under the authority of subsection 6(1) of the Assessment Work Regulation 6/96. Under section 8 of the Mining Act, the information is a public record. This information will be used to review the assessment work and correspond with the mining land holder. Questions about this collection should be directed to the Chief Mining Recorder, Ministry of Northern Development and Mines, 6th Floor, 833 Ramsey Lake Road, Sudbury, Ontario, P3E 6B5

Work Type	Units of Work	Cost Per Unit of Work	Total Cost
Depending on the type of work list the number of hours/days worked, metres of drilling, kilometres of grid line, number of samples, etc.			
NQ Diamond Drilling	2087.5 m. (6849.91 ft)		\$132,469
Sampling/ Assaying	1971 Samples		\$46,590
Labour/ Supervision (PHA)	1.5 months		\$49,933
Report Prod/ Drafting	0.5 months		\$14,929
Associated Costs (e.g. supplies, mobilization and demobilization).			
Office Supplies			\$1,468
NQ core racks			\$2,385
Transportation Costs			
Travel/ food/ accomm	2.17564		\$5,730
Food and Lodging Costs			
Total Value of Assessment Work			\$253,504

**Calculations of Filing Discounts:**

1. Work filed within two years of performance is claimed at 100% of the above Total Value of Assessment Work.
2. If work is filed after two years and up to five years after performance, it can only be claimed at 50% of the Total Value of Assessment Work. If this situation applies to your claims, use the calculation below:

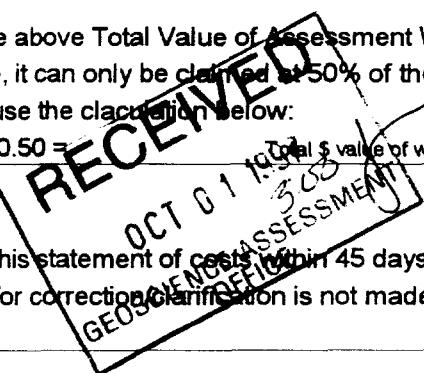

TOTAL VALUE OF ASSESSMENT WORK

x 0.50 =

Total \$ value of worked claimed.

**Note:**

- work older than 5 years is not eligible for credit.
- A recorded holder may be required to verify expenditures claimed in this statement of costs within 45 days of a request for verification and/or correction/clarification. If verification and/or correction/clarification is not made, the Minister may reject all or part of the assessment work submitted.

**Certification verifying costs:**

I, Michael J. Perkins \_\_\_\_\_, do hereby certify, that the amounts shown are as accurate as may  
(please print full name)

reasonably be determined and the costs were incurred while conducting assessment work on the lands indicated on  
the accompanying Declaration of Work form as AGENT

I am authorized

(Recorded holder, agent, or state company position with signing authority)

to make this certification.

## 6. Instructions for cutting back credits that are not approved.

Some of the credits claimed in this declaration may be cut back. Please check (X) in the boxes below to show how you wish to prioritize the deletion of credits.

- 1. Credits are to be cut back from the bank first, followed by option 2 or 3 or 4 as indicated.
- 2. Credits are to be cut back started with the claims listed last, working backwards; or
- 3. Credits are to be cut back equally over all claims listed in this declaration; or
- 4. Credits are to be cut back as prioritized on the attached appendix or as follows (describe):

in following priority 68, 69, 67

Note: If you have not indicated how your credits are to be deleted, credits will be cut back from the bank first, followed by option number 2 if necessary.

---

We have reviewed your Assessment Work submission with the above noted Transaction Number(s). The attached summary page(s) indicate the results of the review. **WE RECOMMEND YOU READ THIS SUMMARY FOR THE DETAILS PERTAINING TO YOUR ASSESSMENT WORK.**

If the status for a transaction is a 45 Day Notice, the summary will outline the reasons for the notice, and any steps you can take to remedy deficiencies. The 90-day deemed approval provision, subsection 6(7) of the Assessment Work Regulation, will no longer be in effect for assessment work which has received a 45 Day Notice.

Please note any revisions must be submitted in DUPLICATE to the Geoscience Assessment Office, by the response date on the summary.

If you have any questions regarding this correspondence, please contact Bruce Gates by e-mail at [gatesb2@epo.gov.on.ca](mailto:gatesb2@epo.gov.on.ca) or by telephone at (705) 670-5856.

Yours sincerely,

A handwritten signature in black ink, appearing to read "Blair Kite".
