1.0 INTRODUCTION

A geological and geophysical survey has been completed on the Kabi Lake grid. The purpose of this program was to delineate the extent of known mineralized zones as well as find new targets. Both magnetics and IP surveys were conducted with several anomalous zones being delineated. Extensive sampling has previously been performed on the property and has yielded values up to 621 gpt Au. Many of these assays appear to be associated with quartz veins.

2.0 LOCATION AND ACCESS

Kabi Lake is located approximately 50 miles northeast of White River. The grid itself is located on the western portion of Kabi Lake along the Bear Creek inlet. (Figure 1)

Access to the property is gained via float plane out of either White River or Wawa, or by helicopter. A logging road comes within 3 km of the grid.

3.0 CLAIMS

The property consists of 18 contiguous claims, staked in September, 1986 and held by D. McKinnon and 11 claims comprising 92 units staked in October and November 1992 and held by Hemlo Gold Mines (Figure 2).

The claims are :

4.0 PREVIOUS WORK

In the 1930's, a small scale mining operation was initiated (Hiawatha Mine). It ran for a few years before being shut down.

Between 1987-1988, prospecting and mapping was conducted on the claims with significant amounts of sampling done. Soil sampling was conducted along with whole rock sampling. Lines were cut previous to work being conducted.

In the summer of 1993, a mapping program was conducted to get a better feel for felsic units within the mafics. It was uncertain as to the extensive or intrusive nature of these units. At some time a geophysical program consisting of both Mag and IP surveys were initiated to help delineate possible drill targets.

5.0 REGIONAL GEOLOGY

The Kabi Lake property lies within the Kabi lake Greenstone Belt, a northeast trending belt of supracrustal lithologies which have been regionally metamorphosed to a mid-to-upper amphibolite facies. These lithologies have been intruded by felsic synvolcanic porphyries which appear to be parallel to stratigraphy.

The Kabi Lake Greenstone Belt is believed to represent the eastern extension of the Hemlo syncline.

6.0 PROPERTY GEOLOGY

The property is underlain primarily by a northeasterly trending sequence of mafic volcanics intruded by high level QFP sills. These units are steeply dipping and appear to be moderately foliated, range from S₁ to S₂ with S₃, being intensely sheared.

The youngest rock appear to be mafic intrusives (gabbro), found predominantly along the north shore of Bear Creek, but can also be found intruding the mafic volcanics south of Bear Creek.

The mafic volcanics range from pillow basalts to tuffs, they are typically fine grained and are commonly chloritized. Quartz stringers are common. North of Bear Creek, the mafics are moderately metamorphosed up to amphibolite facies. It appears some coarse grained flows can be found.

Most of the QFP sills appear to be syngenetic with the mafic volcanics. They are medium grained and commonly contain blue quartz eyes. Quite often they are silicified and contain abundant quartz stringers and quartz veins. These units are what appear to be carrying the gold. The sills range anywhere from 2m to 75m in width and are commonly mineralized with both pyrite and chalcopyrite. Molybdenite is also present in trace amounts. Silicification of this unit appears to be the key in obtaining any kind of gold values.

Ultramafic units also appear to be present as shown by previous wholerock sampling. This is especially evident along the northshore of Bear Creek where silica values are as low as 42%.

Sampling done in the summer of 1993 failed to yield any significant gold values. This could be attributed to the erratic nature of most quartz vein when gold is involved.

7.0 GEOPHYSICAL SURVEY METHOD

7.1 Magnetics

A magnetic survey measures alterations in the earth's naturally occurring magnetic field caused by changes in the magnetization of the rocks in the earth. These changes are due mainly to the presence of the magnetic minerals: magnetite and to a lesser extent pyrrhotite and ilmenite. Mapping these minerals can be an aid to geologic mapping.

The magnetic data were collected with a proton precession magnetometer, which measures the absolute value of the total magnetic field of the earth to an accuracy of ± 0.1 nTesla. Readings are normally taken at 12.5m intervals. Correction for diurnal drift was by reference to a base station magnetometer.

The magnetometer used was a GEM GSM-19.

7.2 Induced Polarization

Induced polarization (IP) and resistivity exploration methods are used to measure the electrical characteristics of the local geology.

An electric voltage is applied to the earth in the form of an on off on-negative off wave. The voltage measured while the current is on is used to calculate the resistivity (resistance to electric current), and the decaying voltage during the off time measures the amount of electric charge that the earth can hold. This charge is held by metallic minerals, and also by clay-like minerals.

Because IP responds to effects on small metallic particles, it is particularly useful for detecting disseminated metallic minerals.

The survey was conducted using a pole-dipole array with a dipole length of 25m and array spacings of $n = 1, 2, 3, 4$ dipoles. This array uses a single transmitter electrode on the grid, and a series of pairs of receiver electrodes spaced at each 'n' interval. The other current electrode is situated 1 kilometre or more from the grid, for this survey along the shore of the lake.

The receiver used was a Scintrex IPR-8, accurate to about 1mV/V chargeability. The transmitter used was a Phoenix IPT-1 3.0kW system with a two second on-time.

8.0 SURVEY STATISTICS

Approximately 12.0km of IP surveying was completed in two phases. A crew from Rayan Exploration of Timmins, Ontario started the project in March 1993, but were forced to quit after 1.7km of surveying due to break-up. A Noranda Exploration crew started work again in June and completed the survey. The Rayan crew was supervised by Ray Meikle of Rayan, Hollinger Bldg, Timmins, and the Noranda crew by Rod Swire of Noranda Exploration, 960 Alloy Dr., Thunder Bay. Overall supervision was by Greg Hodges, Noranda Exploration, Thunder Bay.

The Noranda crew also surveyed 8.7km of magnetics at 12.5km stations.

9.0 INTERPRETATION

The magnetic data showed a strong feature on the north end of most of the lines, reflecting the presence of the mafic-ultramafic volcanics there. Other smaller highs probably reflect diabase dikes, such as have been mapped on the grid.

The induced polarisation data showed a continuous, strong chargeability anomaly across the north end of all the lines, at the edge of the strong magnetic anomaly. Another moderate to strong anomaly lies on the south edge of the two local highs which seem to extend south of the broader high, at 9800N on 10400E to 10800E, and at 9900N on 11800E to 12000E.

A narrow, but still moderate to strong anomaly crosses from 11000E to 11800E at 9300N, and another at 9200N on 11200E and 11400E. Both of these are cut off on their east ends by the grid edge. Another moderate to strong anomaly is at 9300N on 10400E.

10.0 CONCLUSIONS AND RECOMMENDATIONS

The geology mapping in the area of the IP zones detected some sulphide (1-3%) in the area of the anomalies. The strengths of 20 to 30mV/V suggests that there is considerably more sulphide there. Such sulphide is usually part of an alteration zone which is softer than the surrounding rock, and hence lies in the topographic lows.

If the geology in the area is favourable, extension of these lines to the north is recommended to complete the anomalies and look for adjacent zones. At this stage they are detailed enough for a drill hole to be targeted on most lines.

Respectfully submitted,

STATEMENT OF QUALIFICATIONS

I, D. Greg Hedges, of 960 Alloy Drive, in the city of Thunder Bay, Province of Ontario, certify as follows concerning my report on the Kabinikagami Lake in Lizar Township, Province of Ontario and dated November 11, 1993.

1. I am a graduate of Queen's University at Kingston, Ontario with a B.Sc. (Hons.) Geological Sciences with Physics, obtained in 1980.
2. I have been practicing in Canada, and occasionally in the United States, Europe, and Australia for the past fourteen years.
3. The attached report is a product of:
 - a) Examination of data included in the report which was collected on the property concerned.

Dated this 12 day of November, 1993.
Thunder Bay, Ontario

Dear Sir/Madam:

**Subject: APPROVAL OF ASSESSMENT WORK CREDITS ON MINING CLAIMS
P934242 ET AL IN LAZAR TOWNSHIP**

The assessment work credits for Geophysics filed under Section 14 of the Mining Act Regulations have been approved as outlined in the original submission.

The approval date is January 31, 1994.

If you have any questions regarding this correspondence, please contact Lucille Jerome at (705) 670-5855.

Yours sincerely,

Ron C. Gashinski
Senior Manager, Mining Lands Section
