FINAL REPORT
ON
DIAMOND DRILLING
WODIAN OPTION
ASHMORE TOWNSHIP
FOR
NEW BIDLAMAQUE GOLD MINES LIMITED

Summary

An exploratory drill programme of nine holes totalling 1,247 feet was carried out in two areas on claim TB100195. The work under the main trench located two zones of copper mineralization in porphyries. The values were only one-quarter of one percent. The work on the second area under a magnetic anomaly located a zone in two drill holes with a maximum drill hole width 1.7 feet of 1.78% copper. This zone was located in two additional holes but they lacked width and interesting values.

No further work is recommended in connection with this area of copper mineralization.

PINAL REPORT
ON
DIAMOND DRILLING
WODIAN OPTION
ASHMORE TOWNSHIP
FOR
NEW BIDLAMAQUE GOLD MINES LIMITED

I Introduction

Surface trenching and stripping was carried out by John Wodian on this group of twenty claims in Ashmore and Croll Townships. This work was in two pits, on claim TB100195, just 300 feet south of Highway 11.

Surface sampling in May of 1962 by H. Parliment produced channel samples along the strike that contained interesting values in copper and one narrow sample had an appreciable gold assay.

New Bidlamaque optioned a group of twenty claims, shown on the accompanying claim sketch and in mid-June started a programme to survey and drill the area surrounding the showing.

II Access

The showing is accessible from a point 1,000 feet along the highway west of the gravel pit at the south end of Forrester Lake. A tractor road leads from Highway 11, 300 feet south to the pits.

III General Geology

The rocks in the area of the drilling are diorite, feldspar porphyry and quartz - feldspar porphyry. These rocks form an intrusive series of narrow vertical dipping dykes striking approximately N30°E. This series is cut by a narrow north - south striking quartz diabase dyke.

IV Chalcopyrite - Pyrrhotite Mineralization

Three of these bands of feldspar porphyry appear to be altered and bleached and portions of them are replaced in part by chalcopyrite and pyrrhotite mineralization.

V Magnetic Survey

A small picket line grid 700 feet by 500 feet was cut around the pit showing and a magnetic survey was run over this portion of the property (see map 1 inch = 40 feet). The magnetic survey outlined the diabase and two of the zones where the copper sulphide mineralization occurs.

VI Diamond Drilling Programme

Five holes were drilled under the showing in the main pit. This drilling located two copper mineralized zones and the widths varied from 2 to 10 feet but the best assay was in hole 2; 0.18% Cu. over 5.0 feet.

The last four holes were drilled on the second magnetic anomaly centered at 1 + 80S, line 1 + 00W. All four holes located the zone of alteration and mineralization but only holes 6 and 7 located some copper mineralization. Hole 6 intersected 1.1 feet of 1.00% Cu. and hole 7 under six intersected 1.7 feet of 1.78% Cu.

Following this hole 8 was drilled 71 feet to the west and located the altered porphyry and sulphide but without significant values or widths.

Next, hole 9 was drilled under holes 6 and 7 and the copper values and widths were discouraging.

VII Conclusions and Recommendations

The copper zone in holes 6 and 7 did not have sufficient width nor vertical depth to warrant any further attention.

The copper zones under the main pit were too low in values and discontinuous to warrant further exploration. The gold assays associated with a 0.8 foot quartz - calcite vein on surface were located in drilling but gave only trace assays.

No further work is recommended in connection with this area of copper mineralization.

None of the information obtained concerning the Roche - LongLac workings in the southwest portion of the claim group indicated that any exploration for gold should be carried out in this area.

Respectfully submitted,
