MINING LANDS SECTION

Introduction

A horizontal loop electromagnetic (HLEM) survey was carried out on Project 346-Deerfoot Option for Placer Dome Inc. in December 1987. A VLF electromagnetic survey and a total field magnetic survey were also completed on the property in January and February 1988.

The Deerfoot Option consists of 25 unpatented mining claims a list of which is appended to this report. The property is located in the south central portion of Blakelock Township, Ontario. Access to the property was made via helicopter from the town of Cochrane, Ontario which is approximately 90KM S/W of the property. Access was also made via snowmobile along cut trails off of the Detour Lake Mine road.

The purpose of the surveys was to locate subsurface geo-electrical conductors and outline geological structures as revealed by the magnetics which may prove conducive for gold mineralization.

Eight conductors were located by the HLEM survey. Many more conductive horizons were located by the VLF-EM survey. The magnetic survey outlined a well defined rock contact as well as a number of N/S trending dykes.

The accompanying maps show the area surveyed and the results obtained. A technical data sheet is appended to this report.

METHOD AND INTERPRETATION OF RESULTS - ELECTROMAGNETIC SURVEY

Operating Principle: When an electrical conductor is subjected to a primary alternating field, a secondary current is induced in the conductor. This current produces a secondary alternating field which together with the primary field produces a resultant field of different amplitude and phase from the applied primary field. These differences may indicate the presence of a conductor.

Operation: The battery-powered transmitter sets up a primary field while the in-phase and out-of-phase (quadrature) components of the complex secondary vertical field are detected by a receiving coil and measured by means of a compensator-amplifier unit located a fixed distance from the transmitter unit. These parameters are expressed in percentage of the primary field.

Conductor Recognition: The typical curve over a steeply-dipping conductor shows a low (negative - greater than 5%) over the centre of the conductor, flanked by positive readings on both sides of the conductor. Both the in-phase and the out-of-phase components usually produce the same general shape of curve. An asymmetrical curve may indicate one or more of the following conditions: (1) more than one conductor (2) variable conductive overburden (3) a shallow dipping conductor.

Conductivity Determination: The ratio of the amplitudes of the two measured components, in-phase to out-of-phase, is directly proportional to the conductivity of the conductor, in areas of non-conductive overburden.

Conductor Location: For a single conductor, both component readings are normally zero when either the transmitting or receiving coil is directly above the conductor. The location of the conductor is calculated by adding one-half the distance between the transmitting coil and the receiving coil (coil interval) to the co-ordinate at which the readings are zero. A unique solution is generally not possible in the case of multiple conductors spaced less than one coil interval apart. This results in the possibility that an apparently wide conductor may actually consist of two or more narrow conductors.

Depth of Penetration: The maximum depth of penetration for detection of a steeply-dipping conductor in a geo-electrically neutral background is about 0.7 times the coil interval. Over horizontal or flatly-dipping conductors, penetration of up to 1.5 times the coil interval is possible.

Results

Magnetic Survey

The magnetic survey outlines an area with a very disturbed magnetic signature (Maps 88-132-1,-2).

A number of N/S magnetic features are noted and attributed to diabase dykes. These weakly magnetic structures are located along the N/S trending lines on L15+00W, 1+00N to 9+00N and on L7+00W, 3+00N to 9+00N (Map 88-132-2).

The N/W corner of the survey area outlines a non-magnetic, probably granitic, rock unit. The southern edge of this unit delineates the contact between this non-magnetic unit and the more disturbed magnetic unit to the south. The contact follows a NE trend extending from L41+00W, 3+00N to L23+00W, 12+00N (Map 88-131-1). The contact is made up of "highs" and "lows" resulting in a spotted appearance. This is typical of areas which have little overburden cover.

Several smaller features are noted on the contour map. Examples of these are as follows:

1. A NW trending feature is noted extending from L24+00W, 3+75N to L21+00W, 2+00N.
2. A NE trending feature is noted extending from L20+00W, 5+00N to L17+00W, 7+00N.
3. A NE trending feature, parallel to the contact, is noted extending from L25+00W, 7+00N to L27+00W, 6+00N.

HLEM Survey

The HLEM survey was carried out using a 100 metre coil interval with frequencies of 1777 Hz and 444 Hz (Maps 88-130-1,2). The data obtained on the EW crosscutting lines was plotted on a separate map, Map 88-130-1a, for ease of viewing. The conductors plotted on the HLEM map sheets incorporates the information from the surveys run in both line directions.

The following table lists the eight conductors located.

Conduct	Map Sheet	Line	Station	Apparent Max. Width	IP/OP Ratio		Magnetic Correlation	Magnetic Value	Depth Estimate		σ_t HF	LF

Conductor #1 is a strong conductor becoming less conductive towards its eastern extremity. It coincides with the rock contact observed from the magnetic data.

Conductor #2 is an indefinite conductor.

Conductors #3, #4, and #5 are in close proximity and are associated with a disturbed magnetic pattern. Conductor #3 is quite wide and extremely conductive yet has a limited strike length. Conductor #5 may be along a rock contact.

Conductor #6 is a long weak conductor with a depth estimate of approximately 33 metres. It does not coincide with any magnetic structure yet appears quite long and continuous. At its northern extremity where it is close to conductors #3 and #4, the profiles become quite disturbed. This coupled with the observance of a long positive shoulder of condutor #4 on L25+00W, at approximately 6+00N, suggests there may be a N/S striking conductor located between lines 26+00W and 25+00W at approximately 6+00N.

Conductor #7 has poor conductivity and is classified as indefinite. It may reflect surficial conductivity.

Conductor #8 is a one line conductor with a depth estimate of 44 to 50 metres. Its strike direction is uncertain due to its short strike length.

VLF Electromagnetic Survey

The North-south lines were read using the transmitting station at Cutler, Maine. The survey data was posted and profiled (Maps 88-132-1,2). The inphase data was "fraser filtered" to produce a contour map of the conductive horizons (Maps 88-133-1,2). The east west cross lines were read using the transmitting station at Annapolis, Maryland. This data was posted and profiled (Map 88-132-1a) however, due to the wide line spacing was not "fraser filtered".

The strongest anomalies are listed below.

<u>VLF Conductor #</u>	<u>Western Extremity</u>	<u>Eastern Extremity</u>
1	L38+00W, 4+00N	L31+00W, 7+25N
2	L36+00W, 4+50N	L30+00W, 7+00N
3	L27+00W, 7+75N	L25+00W, 7+50N
4	L37+00W, 3+00N	L36+00W, 3+00N
5	L25+00W, 3+00N	L20+00W, 1+00N
6	L19+00W, 11+50N	L10+00W, 10+50N
7	L12+00W, 11+50N	L7+00W, 5+50N
8	L2+00N, 27+30W	L4+00N, 26+33W

VLF conductors #1 and #2 coincide with the wide HLEM conductor #1.

VLF conductor #3 coincides with HLEM #5, however the VLF response is stronger.

VLF conductor #4 coincides with HLEM #2, however, the VLF response is stronger.

VLF conductor #5 follows a NW magnetic trend with no apparent coincident HLEM conductor.

VLF conductor #6 follows HLEM #7 but extends beyond the limits of the HLEM conductor.

VLF conductor #7 is a long conductor which coincides with HLEM #8 which has a very short strike length.

VLF conductor #8, located on the EW trending lines concides with HLEM #6.

Conclusions and Recommendations

With a few exceptions, the conductors follow an east-west trend perpendicular to the line direction. Most of the VLF conductors located, which were also located by the HLEM system, appear to be stronger and have a greater strike length with the VLF survey. This is due to the ability of the VLF system to locate very weakly conductive features which have a long strike extent. The horizontal loop system is designed to locate more conductive, and discreet conductors. The VLF system, however, is affected by resistivity contrasts, conductive overburden, and steep topographical changes. Therefore caution must be used when interpreting VLF anomalies.

The conductive zones which require additional investigation are:

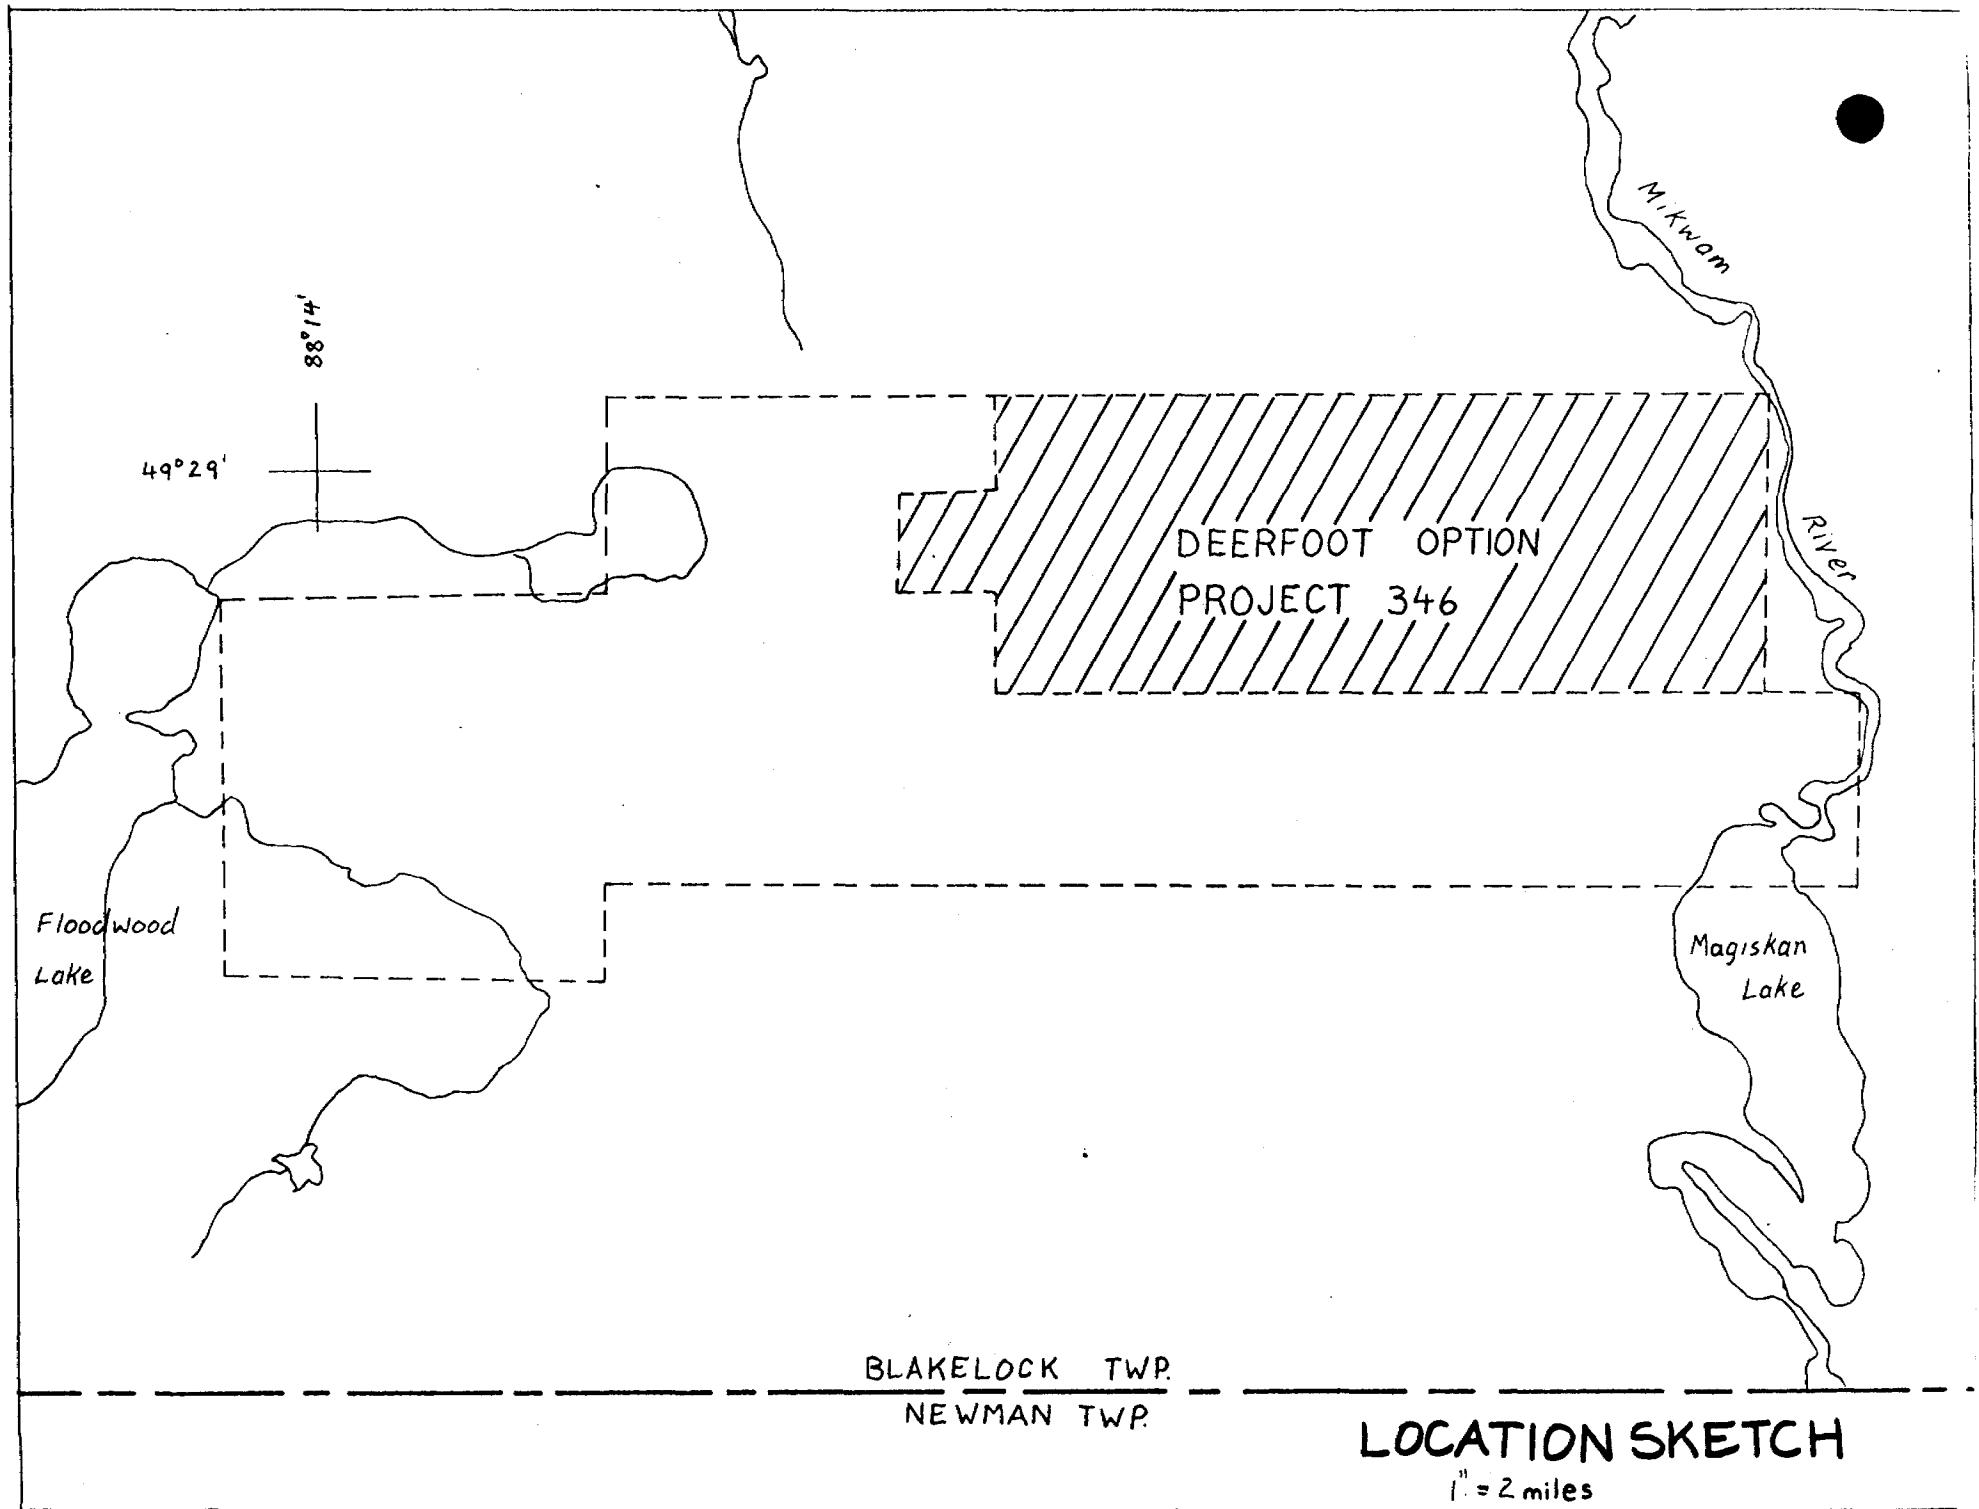

- HLEM Conductors # 1 - which lies along the rock contact
3 - which has a short strike extend yet is quite wide
6 - which appears to follow no magnetic trend
8 - which is a one line conductor

Further work should be planned after correlation of the data presented with the known geology.
