1. INTRODUCTION

This report describes the specifications and results of a geophysical survey carried out for Casau Exploration Ltd. of 1458 Rupert Street, North Vancouver, B.C., V7J 1E9 by Terraquest Ltd., 905 - 121 Richmond Street West, Toronto, Canada. The field work was performed on December 15, 1986 and the data processing, interpretation and reporting from December 16, 1986 to February 27, 1987.

- 1 -

The purpose of a survey of this type is two-fold. One is to prospect directly for anomalously conductive and magnetic areas in the earth's crust which may be caused by, or at least related to, mineral deposits. A second is to use the magnetic and conductivity patterns derived from the survey results to assist in mapping geology, and to indicate the presence of faults, shear zones, folding, alteration zones and other structures potentially favourable to the presence of gold and base-metal concentration. To achieve this purpose the survey area was systematically traversed by an aircraft carrying geophysical instruments along parallel flight lines spaced at even intervals, 100 metres above the terrain surface, and aligned so as to intersect the regional geology in a way to provide the optimum contour patterns of geophysical data.

2. THE PROPERTY

The property is located in the northeast corner of Bragg township and in the northwest corner of Newman township, in the Larder Lake Mining Division of Ontario about 70 kilometres northeast of the town of Cochrane. The claims can be approached by bush roads which come to the western side of Bragg township.

The latitude and longitude are 49 degrees 26 minutes, and 80 degrees 12 minutes respectively, and the N.T.S. reference is 42H/8.

The claim numbers are shown in figure 2 and listed below:

Bragg To	ownship L	882642-882657	(16)	
	\mathbf{L}	882667-882670	(4)	
Newman 1	Fownship L	832803-832809	(7)	
	L	877941-877953	(13)total 4	40 claims

and the second

2. Map 2410: Twopeak Lake. scale 1:31,680. O.G.S. 1978

There are no mapped outcrops within the survey area; the geology is extrapolated from adjacent outcrops. The western half of the claim block is thought to be underlain by mafic metavolcanics. The eastern half is underlain by a tongue of felsic intrusives surrounded by clastic metasediments. Iron formations, pyrrhotite, pyrite and chalcopyrite occur in both the metasediments and metavolcanics. North trending diabase dykes cut through the region.

-2-

This geology is not entirely consistent with the regional aeromagnetic maps which indicate an east-west trending, strong anomaly that extends across the entire northern part of the survey area.

The survey was carried out using a Cessna 182 aircraft, registration C-FAKK, which carries a magnetometer and a VLF electromagnetic detector.

The magnetometer is a proton precession type based on the Overhauser effect. The Overhauser effect allows for polarization of a proton rich liquid of the sensor by adding a "free radical" to it and irradiating it by RF magnetic field. Strong precession signals are generated with modest RF power. The sensor element is mounted in an extension of the right wing tip. It's specifications are as follows:

	\cdots
Resolution:	0.5 gamma
Accuracy:	0.5 gamma
Cycle time:	0.5 second
Range:	20,000 - 100,000 gammas in 23 overlapping steps
Gradient tolerance:	Up to 5000 gammas per metre
Model:	GSM-9BA
Manufacturer:	GEM Systems Inc., 105 Scarsdale Rd.,
	DON MILLS, UNCALLO, MOD ZKO

The VLF-EM unit uses three orthoganol detector coils to measure (a) the total field strength of the time-varying EM field and (b) the phase relationship between the vertical coil and both the "along line" coil (LINE) and the "cross-line" coil (ORTHO). The LINE coil is tuned to a transmitter station that is ideally positioned at right angles to the flight lines, while the ORTHO coil transmitter should be in line with the flight lines. It's specifications are:

Accuracy:	18
Reading interval:	1/2 second
Model:	TOTEM 2A
Manufacturer:	Herz Industries, Toronto

The VLF sensor is mounted in the left wing tip extension.

Other instruments are:

King KRA-10A Radar altimeter

. UDAS-100 data processor with Digidata nine track tape recorder, manufactured by Urtec Ltd., Markham, Ontario.

Geocam video camera and recorder for flight path recovery, manufactured by Geotech Ltd., Markham, Ontario.

4.2 Lines and Data

a)	Line spacing:	200 metres
b)	Line direction:	360 & 090 degrees
c)	Terrain clearance:	100 metres
d)	Average ground speed:	156 km/hr.
e)	Data point interval:	,
	- Magnetic:	27 metres
	VLF-EM:	27 metres
f)	Tie Line interval:	not applicable in bidirectional survey
g)	Channel 1 (LINE):	E-W Grid: NAA Cutler, 24.0 kHz
-		N-S Grid: NLK Seattle, 24.8 kHz
h)	Channel 2 (ORTHO):	E-W Grid: NLK Seattle, 24.8 kHz
		N-S Grid: NSS Annapolis. 21.4 kHz
i)	Line km over total survey	v area including overrun: 105 line km
j)	Line km over claim groups	: Magnetic survey totals 83 line km
	_	VLF-EM survey totals 83 line km

4.3 Tolerances

a) Line spacing: Any gaps wider than twice the line spacing and longer than 10 times the line spacing were filled in by a new line.
b) Terrain clearance: Portions of line which were flown above 125 metres for more than one km were reflown if safety considerations were acceptable.

c) Diurnal magnetic variation: Less than twenty gammas deviation from a smooth background over a period of two minutes or less as seen on the base station analogue record.

d) Manoeuvre noise: Approximately +/-5 gammas.

4.4 Photomosaics

For navigating the aircraft and recovering the flight path, mosaics of aerial photographs were made from existing air photos.

5. DATA PROCESSING

- - Harrison

Flight path recovery was carried out in the field using a video tape viewer to observe the flight path as recorded by the Geocam video camera system. The flight path recovery was completed daily to enable reflights to be selected where needed for the following day.

-4-

The magnetic data was levelled in the standard manner by tying survey lines to the tie lines. The IGRF has not been removed. The total field was contoured by computer using a program provided by Dataplotting Services Inc. To do this the final levelled data set is gridded at a grid cell spacing of 1/10th of an inch at map scale.

The vertical magnetic gradient is computed from the total field data using a method of transforming the data set into the frequency domain, applying a transfer function to calculate the gradient, and then transforming back into the spatial domain. The method is described by a number of authors including Grant, 1972 and Spector, 1968. The computer program for this purpose is provided by Paterson, Grant and Watson Ltd. of Toronto

The VLF data was treated automatically so as to normalize the non conductive background areas to 100 (total field strength) and zero (quadrature). The algorithms to do this were developed by Terraquest and will be provided to anyone interested by application to the company.

All of these dataprocessing calculations and map contouring were carried out by Dataplotting Services Inc. of Toronto.

INTERPRETATION

6.1 General Approach

To satisfy the purpose of the survey as stated in the introduction, the interpretation procedure was carried out on both the magnetic and VLF data. On a local scale the magnetic gradient contour patterns were used to outline geological units which have different

Grant, F.S. and Spector A., 1970: Statistical Models for Interpreting Aeromagnetic Data; Geophysics, Vol 35

-5-

magnetic intensity and patterns or "signatures". Where possible these are related to existing geology to provide a geological identity to the units. On a regional scale the total field contour patterns were used in the same way.

Faults and shear zones are interpreted mainly from lateral displacements of otherwise linear magnetic anomalies but also from long narrow "lows". The direction of regional faulting in the general area is taken into account when selecting faults. Folding is usually seen as curved regional patterns. Alteration zones can show up as anomalously quiet areas, often adjacent to strong, circular anomalies that represent intrusives. Magnetic anomalies that are caused by iron deposits of ore quality are usually obvious owing to their high amplitude, often in tens of thousands of gammas.

VLF anomalies are categorized according to whether the phase response is normal, reverse, or no phase at all. The significance of the differing phase responses is not completely understood although in general reverse phase indicates either overburden as the source or a conductor with considerable depth extent, or both. Normal phase response is theoretically caused by surface conductors with limited depth extent.

Areas showing a smooth response somewhat above background (ie. 110 or so) are likely caused by overburden which is thick enough and conductive enough to saturate at these frequencies. In this case no response from bedrock is seen.

The VLF-EM conductor axes have been identified and evaluated according to the Terraquest classification system (Figure 4). This system correlates the nature and orientation of the conductor axes with stratigraphic, structural and topographic features to obtain an association from which one or more origins may be selected. Alternate associations are indicated in parentheses.

6.2 Interpretation

The magnetic and VLF-EM data are shown in contoured format on maps in the back pocket. A first pass interpretation map is also provided. The following notes are intended to supplement these maps.

The total magnetic field has a relief of approximately 415 gammas and shows the general trend of the lithology. It is consistent with the regional aeromagnetic survey but shows considerably more detail. The vertical magnetic gradient provides further resolution of minor stratigraphic trends and dykes.

The weakest magnetic responses to the southeast are interpreted to represent the felsic intrusives (Unit 4). It is difficult to determine

-6-

the contacts of weakly magnetic units. However, the lack of a definite fold nose suggests that this intrusive may be a conformable feature rather than a structural fold.

The strongest magnetic responses are interpreted to be iron formation. These may be broad lean iron formations or narrow, strongly magnetic horizons, possibly as multiple horizons. The responses from strongly magnetic rocks generally overwhelm the magnetic fields from adjacent lithologies, hence the magnetically interpreted widths of iron formations are often exaggerated.

Alternatively these strongly magnetic horizons may represent alteration zones associated with the felsic intrusive. These may occur at or beyond the intrusive contact and are often characterized by alteration of nonmagnetic iron minerals to their magnetic forms. Such a model is hypothetical at this stage and would require ground verification.

The intermediate to low magnetic responses are interpreted to represent the clastic metasediments (Unit 2). This is a subjective interpretation as they occur next to and are overwhelmed by the iron formations. Horizons of higher magnetic activity (Unit 2m) may be related to increased concentrations of pyrrhotite or magnetite, or possibly to mafic volcanic intercalations.

The moderate to strong magnetic responses to the north are interpreted to be mafic metavolcanics (Unit 1). The more magnetic areas (Unit 1m) probably represent more mafic metavolcanics or mafic intrusives, or possibly horizons with increased concentrations of pyrrhotite or magnetite.

The crosscutting moderate to strong anomaly to the east is interpreted to be a diabase dyke (Unit 5). It does not appear to cut the felsic intrusives.

Magnetically interpreted faults trend to the north northwest parallel to the diabase dyke.

The VLF-EM responses are weak to moderate and in general possess poor definition. The lack of good responses may be related to masking by conductive overburden.

The north trending conductor axes have been interpreted as faults, suggesting that there may be more faulting than detected by magnetic methods. Conductivity in faults may be related to (a) mineralogical sources such as gouge, graphite or sulphides, or to (b) ionic sources such as porosity within the fault or clay in a topographic depression over the fault. Faults identified by magnetic or VLF-EM methods may provide the primary structural for epithernal mineralization.

TERRAQUEST LTD.

and the second

学生を書き

しためとなり、「ないない」

Ð,

Several weak conductor axes coincide with or parallel the magnetic stratigraphy. These possess potential for stratabound, mineralogic sources and should be followed up on the ground using EM or IP techniques.

-7-

7. SUMMARY

An airborne combined magnetic and VLF-EM survey has been done on the property at line intervals of 200 metres in two directions. The total field and vertical gradient magnetic data, VLF-EM data and interpretation maps are produced at a scale of 1:10,000.

The magnetic data has been used to modify and update the existing geology and has shown a number of new contacts and faults. A number of VLF-EM conductor axes were found of which some are believed to have potential sulphide origins and have been recommended for additional investigation.
