1 INTRODUCTION

Scott Hogg & Associates were contracted in July, 2001 to carry out an interpretation of ground magnetic survey data collected over the MacFadyen 1 and 2 kimberlite pipes, located south of the Attawapiskat River in the James Bay Lowlands of Northern Ontario. This report describes the work done, results obtained and recommendations for further investigation.

2 LOCATION

The location of the mining claims, near the Attawapiskat River, is presented on the map below (figure 1).

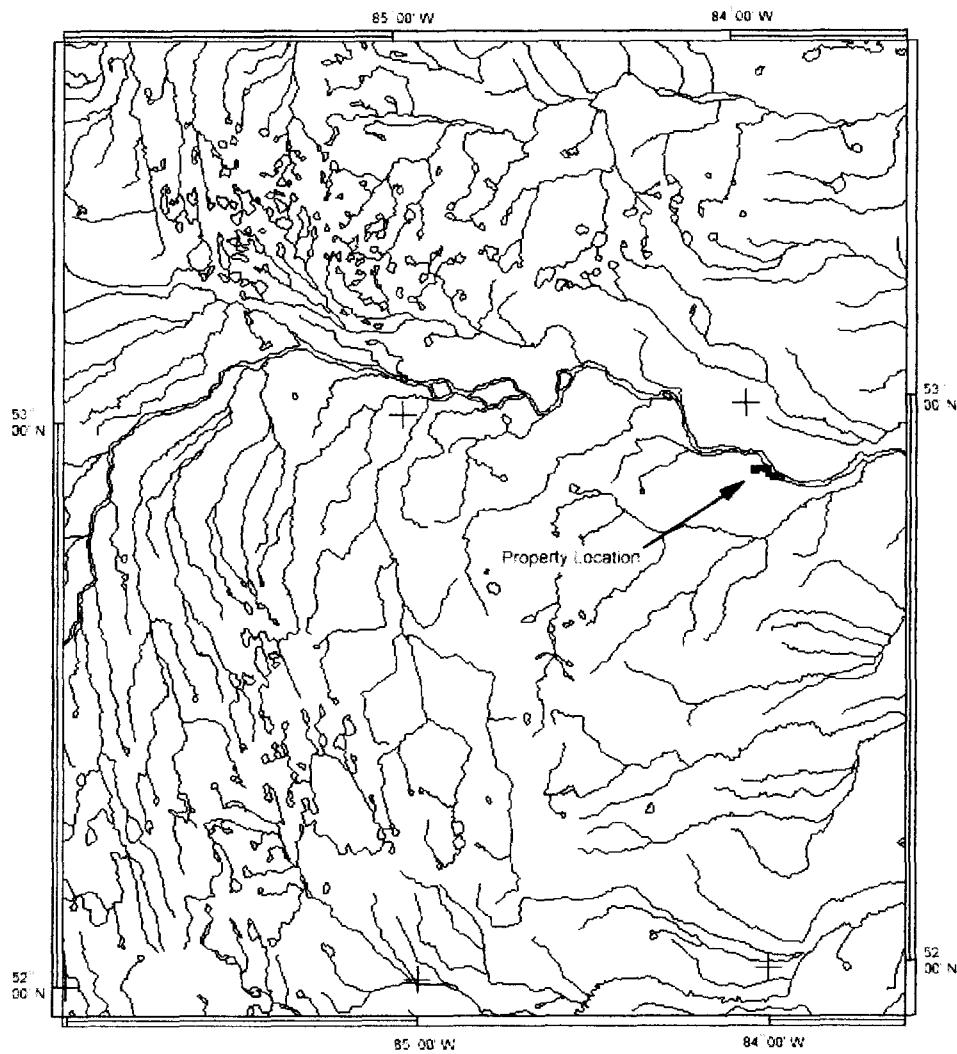

Figure 1 - Property Location Map

A map of the claim group and the ground magnetic survey grid is presented below as Figure 2.

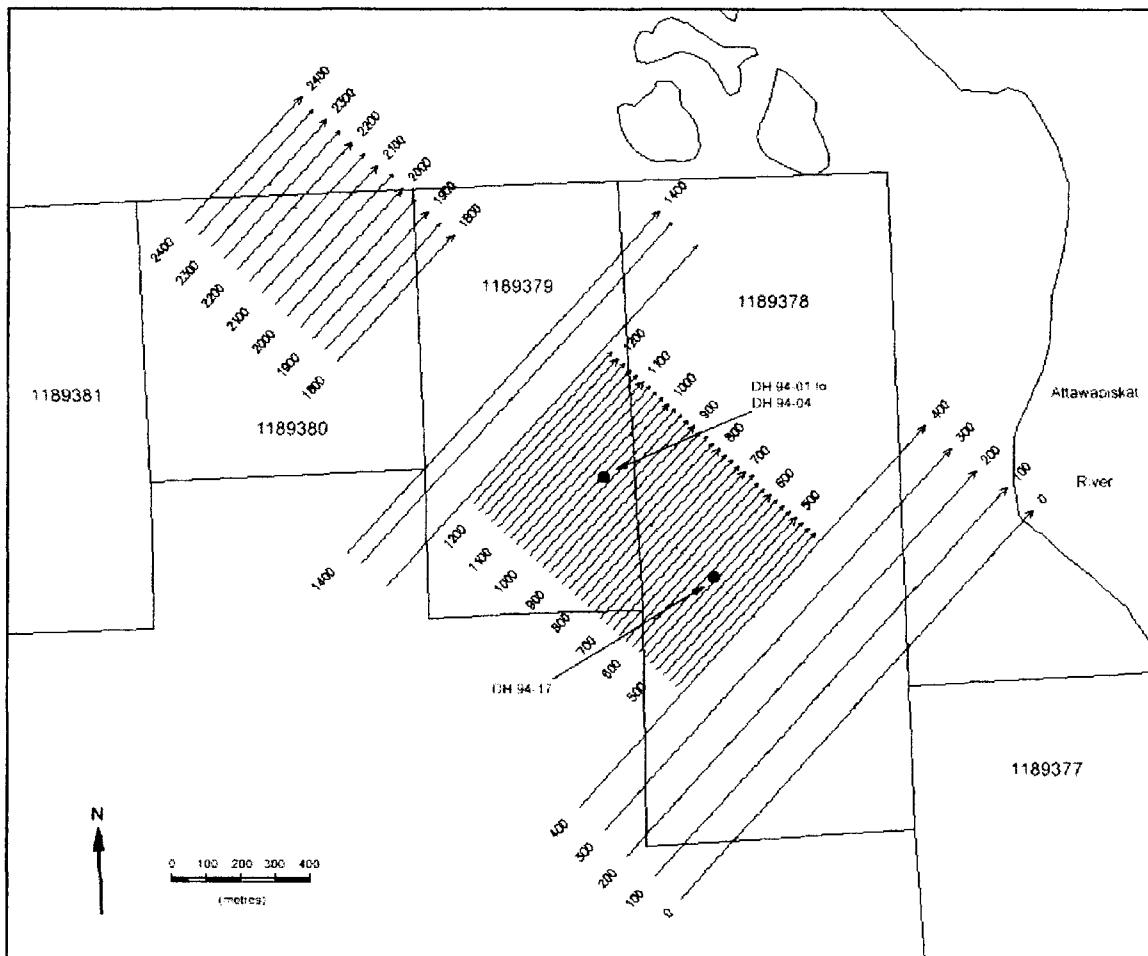

Figure 2 - Claim Map and Survey Grid

3 ANALYSIS PROCEDURE APPLIED

The magnetic data was available in digital profile format, corrected for diurnal variation. The profile data was interpolated using the SI-GRID process, a gridding technique developed by Scott Hogg & Associates Ltd. A total field magnetic map was produced with a 2nT contour interval as presented in figure 3.

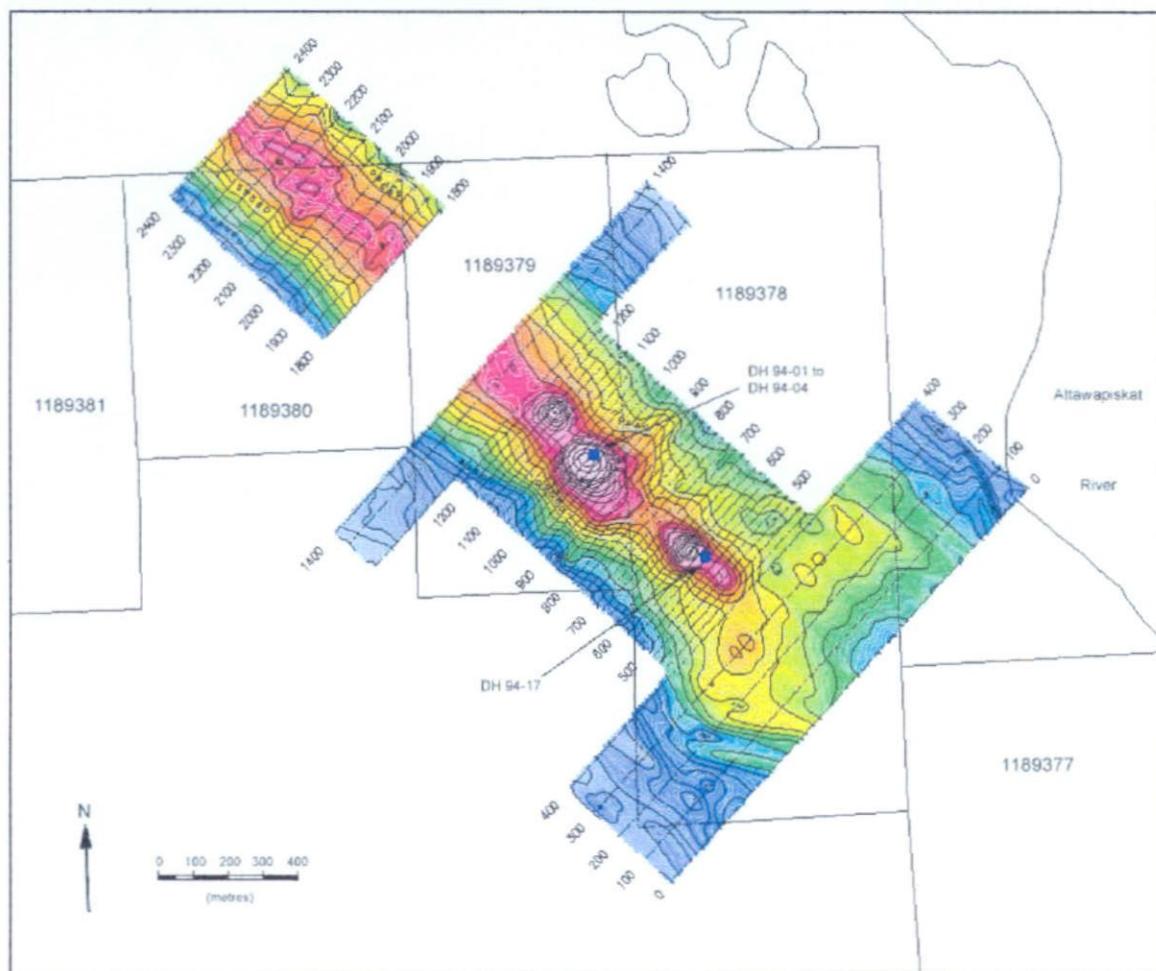

Figure 3 - Total Magnetic Field with 2, 10 and 50 nT Contours

The dominant feature of the map is a magnetic linear trending NW-SE upon which are superimposed several stronger ovoid anomalies. The MacFadyen 1 kimberlite pipe is associated with one of these features centered on line 1000 and drill tested by holes 94-01 to 94-04 as indicated. The MacFadyen 2 kimberlite pipe, at line 600, was tested by the indicated drill hole 94-17.

One objective of the interpretation was to improve the delineation of the MacFadyen pipes and possibly identify other shallow kimberlites. A second objective was to analyze

the underlying linear magnetic feature and determine its relationship to the kimberlite pipes.

To facilitate profile data analysis of the superimposed pipe anomalies, a "stripping" process was adopted to separate the two anomalies. The objective was to divide the observed profile response into two components; one representing the linear feature and the other representing the shallower detail which included the kimberlite pipes. A profile or grid filter approach could not adequately separate the anomalies and the method adopted was to fit a low order spline to the deeper linear anomaly, profile by profile. The control points for the spline were located away from the shallow anomalies in order to optimize anomaly separation. The spline profiles, representing the magnetic response attributed to the deeper linear source were then modeled using the Geosoft Magmod program. The physical model was a finite strike length prism of variable dip, depth, width, thickness and susceptibility parameters. Each profile was individually fit and the body parameters as well as the associated theoretical profile were saved.

The theoretical magnetic profiles, stemming from the interpretation of the deeper linear magnetic anomaly, were subtracted from the total field profile to create a residual magnetic profile. This residual magnetic component represents the near surface magnetic response that includes the kimberlite anomalies. Maps of the deeper linear anomaly, based on the theoretical profiles are presented in figure 4 and 5, and a map of the residual response; total field minus the deeper theoretical response, is presented in figure 6. These shallow anomalies were modeled, line by line, using the same prism model as applied to the underlying linear magnetic trend. The modeling results for both the deeper linear anomaly and the shallower residual anomalies are presented in Appendix 1.

4 INTERPRETATION AND DISCUSSION

4.1 Linear Magnetic Anomaly

On most of the profiles the full lateral extent of the anomaly was not covered by the survey. Without definition of the flanks, the modeling process can become highly variable if a reference base line is not fixed. The full profile definition of the linear magnetic anomaly was best presented on the longer survey lines 1250, 1350 and 1400. These lines were modeled first and a magnetic base level and slope, that was most compatible with the three profiles, was identified and adopted for all profiles. The variable model parameters were position, dip, depth, width, thickness and susceptibility.

The model results are presented in Table 1 and the tops of the modeled prisms are shown on a total field magnetic background in Figure 4.

Line Number	Depth (m)	Half Width (m)	Dip	Thickness (m)	Susceptibility (emu)
0	172	529	90	24.5	0.00427

Table 1 - Model Results of Deep Linear Feature - First Pass
(note: dip is measured from the northeast horizon, 90=vertical)

A change in the nature of the total field representation as well as the first pass model results was evident between line 400 and line 700. Between lines 0 and 400 the anomaly is a broad zone without the linear characteristics evident to the northwest. The implied width is about 1 kilometre, implied depth 200 to 250 metres with a vertical

thickness of 25 to 50 metres.. These magnetic modeling results for lines 0 to 400 suggest a flat lying magnetic source that could be a sill or a local basement uplift.

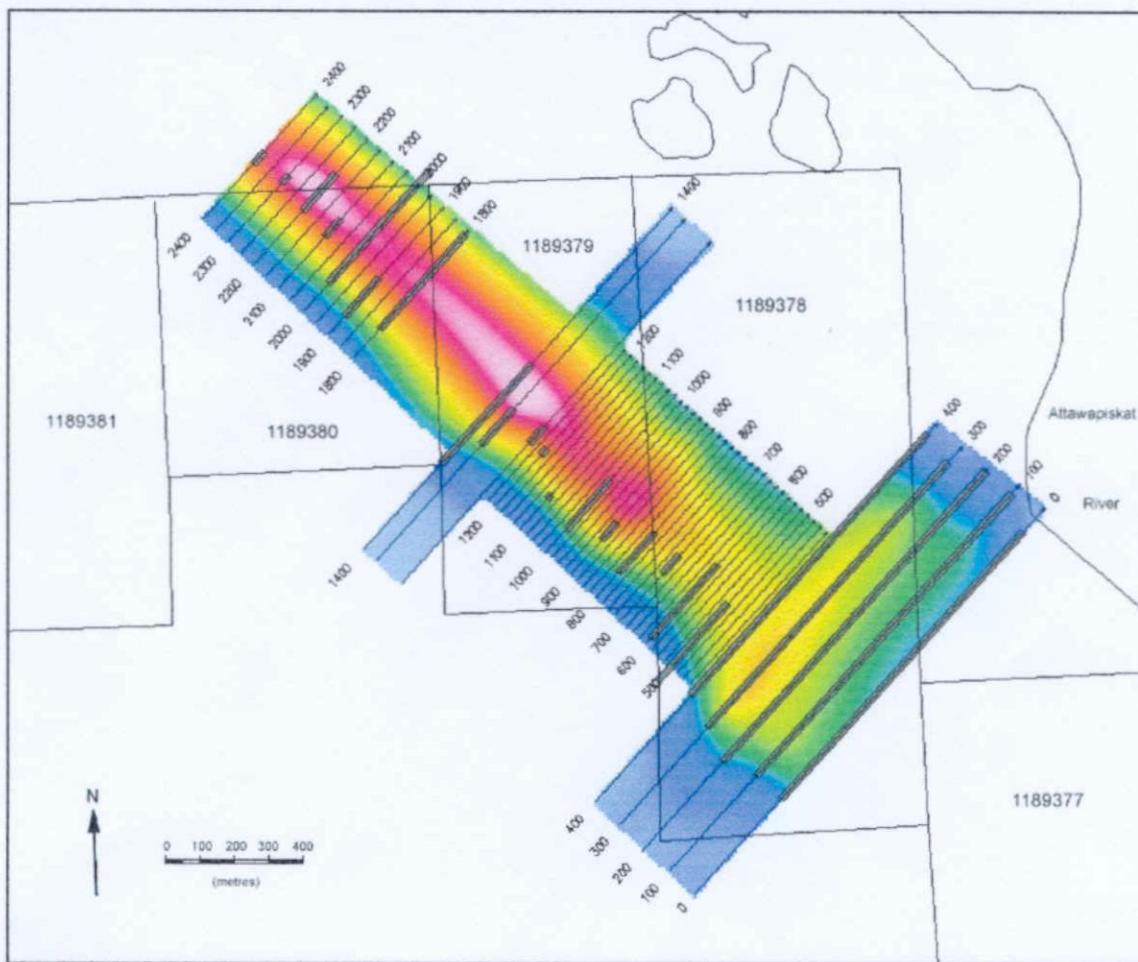

Figure 4 - Deep Linear Feature, First Pass Model
(Showing Tops of Modeled Bodies)

The linear feature starts to become well defined about Line 700 and continues to the northwest margin of the survey area. The modeled depth is generally in the range of 300 to 330 metres and the vertical thickness sufficiently large to imply a source of significant depth extent. The estimated horizontal width ranges between 20 and 400 metres and this variability is attributed to the width being a poorly determined and hence unstable model parameter, not geological variation. The same instability is evident in the susceptibility estimates that range from 0.002 to 0.03 emu. A transition of modeled dip, from about 60 degrees in the northwest to about 30 degrees to the southeast may reflect a real geological change.

A second pass modeling operation was carried out with a reduced number of variables. The width of the body was fixed at 100 metres and the vertical thickness (depth extent) was set to 2000 metres. The modeling of intermediate lines profiles ($xx+50$ NW) was carried out using the same magnetic base line as above. The results are presented in

2.24050

table 2 and figure 5. From line 650 to line 2350 the values for susceptibility, depth and dip are quite stable. The modeled susceptibility is 0.005 emu plus or minus about 20 percent. If the width of the feature were increased, these susceptibility values would decrease or if the width were decreased these values would increase such that the product of susceptibility and width remain near constant. Discounting the calculated depths on lines 450 to 650 near the end of the linear, the results consistently imply a source depth of about 280 metres below surface. As in the first modeling pass, there is a suggestion that the dip decreases from about 60 degrees in the northwest to perhaps 40 degrees towards to southeast end of the linear. The results on lines 450 and 550 reflect the transition towards the flat lying characteristics, evident on lines 0 to 400.

Line Number	Depth (m)	Half Width (m)	Dip	Thickness (m)	Susceptibility (emu)

(Showing Tops of Modeled Bodies)

4.2 Shallow Magnetic Anomalies

The shallow residual magnetic response, calculated by subtraction of the linear anomaly from the total field profile, was modeled line by line. A map of the residual magnetic response, together with the tops of the modeled bodies, is presented in Figure 6. It is apparent from the model results that the MacFadyen 1 pipe has two satellite features that have been designated MF1-N and MF1-S. These anomalies are almost certainly kimberlite and may be side-lobes to an irregularly shaped MacFadyen 1 pipe or discrete separate intrusives. Also apparent is a satellite to the MacFadyen 2 pipe, designated MF2-S, which also may be a side-lobe or a discrete and separate pipe.

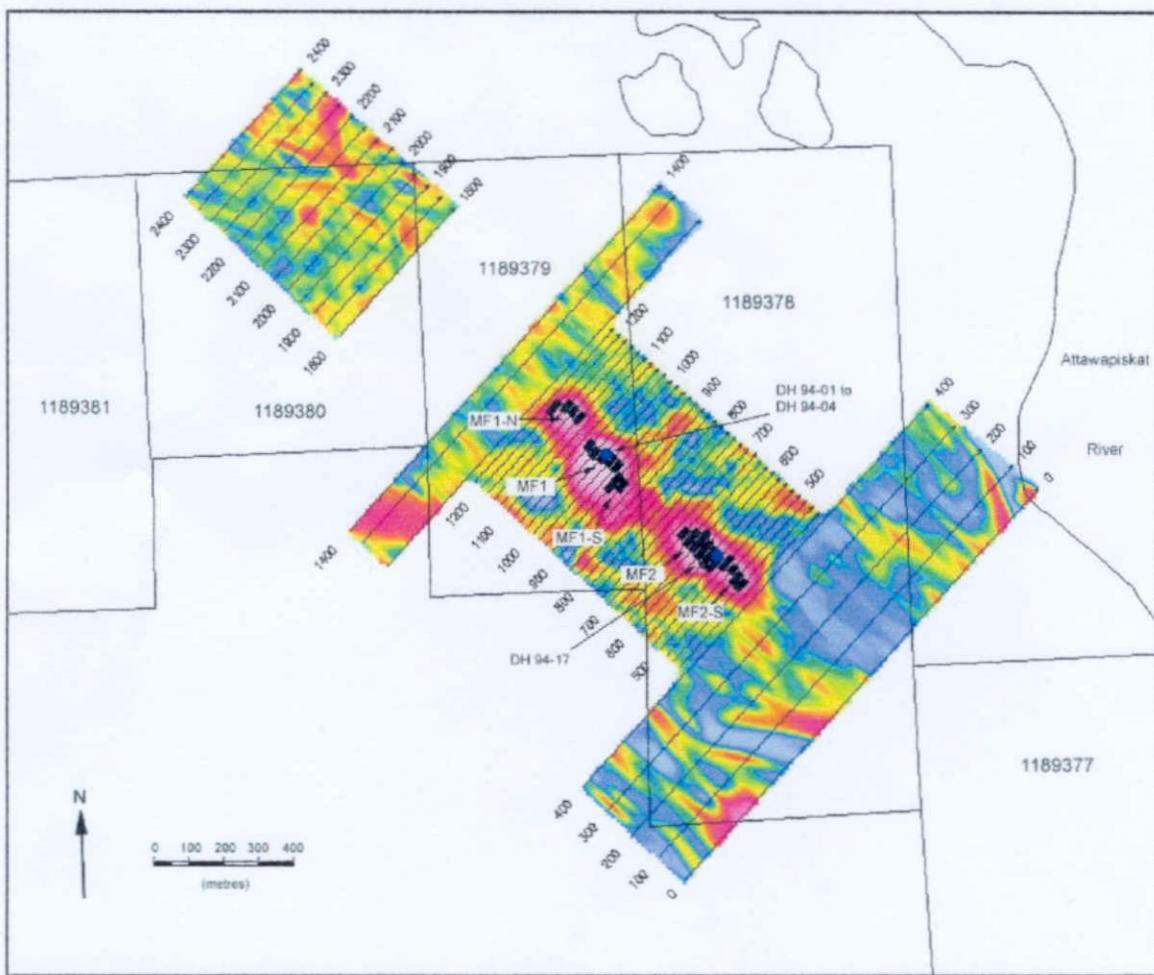

Figure 6 - Residual Magnetic Component

MacFadyen 1

The survey lines 975 to 1025 indicate a consistent depth of about 43 metres and are interpreted as passing over the pipe. The slight increase in depth on line 950 and 1050 is attributed to end-effect, an increase in modeled depth that occurs when a line is adjacent to but not over the causative body. The drilled depth of the pipe was 32 metres and the slightly greater modeled depth might be attributed to a more weathered and less magnetic upper layer or simply a reflection of the limitations of the magnetic method. The width of the body is reasonably indicated as about 40 metres and the dip at 110 degrees is near vertical but inclined slightly to the southwest. The susceptibility is about 0.0043 emu.

The principal profiles of the MF1-n body are lines 1150 and 1175 that provide an indicated depth of about 45 metres, similar to MF1. The increased depth of flanking lines, 1125 and 1175 is attributed to end-effect as noted above. The body displays a near vertical but slight southwest dip of about 105 degrees. For the two principal profiles the modeled results imply a limited depth extent of about 150 metres and lower susceptibility of 0.0022 emu. Experimentally the depth extent was substantially increased and little change in the susceptibility or quality of fit resulted. It is thus likely that the susceptibility of the body is less than for the MacFadyen 1 pipe and possible that the body tapers more rapidly with depth.

The MF1-s pipe has a susceptibility of 0.004 emu, similar to the MF1 pipe but a significantly greater depth of about 95 metres below surface. Again the dip is near vertical.

Body	Line No.	Depth (m)	Half Width (m)	Dip (deg)	Thickness (m)	Susceptibility (emu)
MF1-s	900	97.2	20	106	1000	0.00406
MF1-s	925	93.7	32	72.6	1000	0.00345
MF1	950	54.7	20	127	2699	0.00359
MF1	975	45.7	20	123	1000	0.0043
MF1	1000	42.7	20	109	2873	0.00466
MF1	1025	42.4	17.9	92.1	3310	0.00429
MF1	1050	54.6	18	117	152	0.00339
MF1-n	1125	54.4	20	109	1000	0.0016
MF1-n	1150	43.8	15.3	107	170	0.00222
MF1-n	1175	51.3	20	104	141	0.00221
MF1-n	1200	65.1	25	67.2	2377	0.00143

Table 3 - Model Results for MacFadyen 1

MacFadyen 2

The model results over the MacFadyen 2 pipe indicate a depth of about 40 metres below surface on the three principal profiles; 575, 600 and 625. The deeper depths on lines 550, 650 and 675 may be attributed to end-effect. The drilled depth of MacFadyen 2 was 96m, but as seen in Figure 6, the hole was not centered on the body and may have entered the side of the pipe at depth. The indicated dip is near vertical and the susceptibility is about 0.0013 emu, about 25 percent of that estimated for MacFadyen 1.

The MF2-s body appears to be somewhat deeper with indicated depths of 50 metres on the principal lines 475 and 500. The apparent dip is near vertical but inclined slightly to the northeast. The susceptibility of 0.0018 emu is slightly higher than that of MF2.

Body	Line No.	Depth (m)	Half Width (m)	Dip (deg)	Thickness (m)	Susceptibility (emu)
MF2-s	425	85.8	28.7	67.8	2558	0.0023
MF2-s	450	64.9	20	60	2934	0.0023
MF2-s	475	50.8	21.7	68.1	2876	0.00153
MF2-s	500	49.8	15	83.7	2602	0.00189
MF2-s	525	66.9	25	94.8	2000	0.00193
MF2	550	56.5	24	44.4	2622	0.00201
MF2	575	42.4	34	72.9	1000	0.00144
MF2	600	37.9	33.7	92.3	2623	0.00146
MF2	625	40.3	38.8	108	1574	0.00114
MF2	650	50.4	32	93.4	2434	0.00122
MF2	675	52.5	17.9	83.2	2255	0.00176

Table 4 - Model Results for MacFadyen 2

5 CONCLUSIONS AND RECOMMENDATIONS

The interpretive map presented in figure 7 presents an interpretation of the model results presented and discussed above.

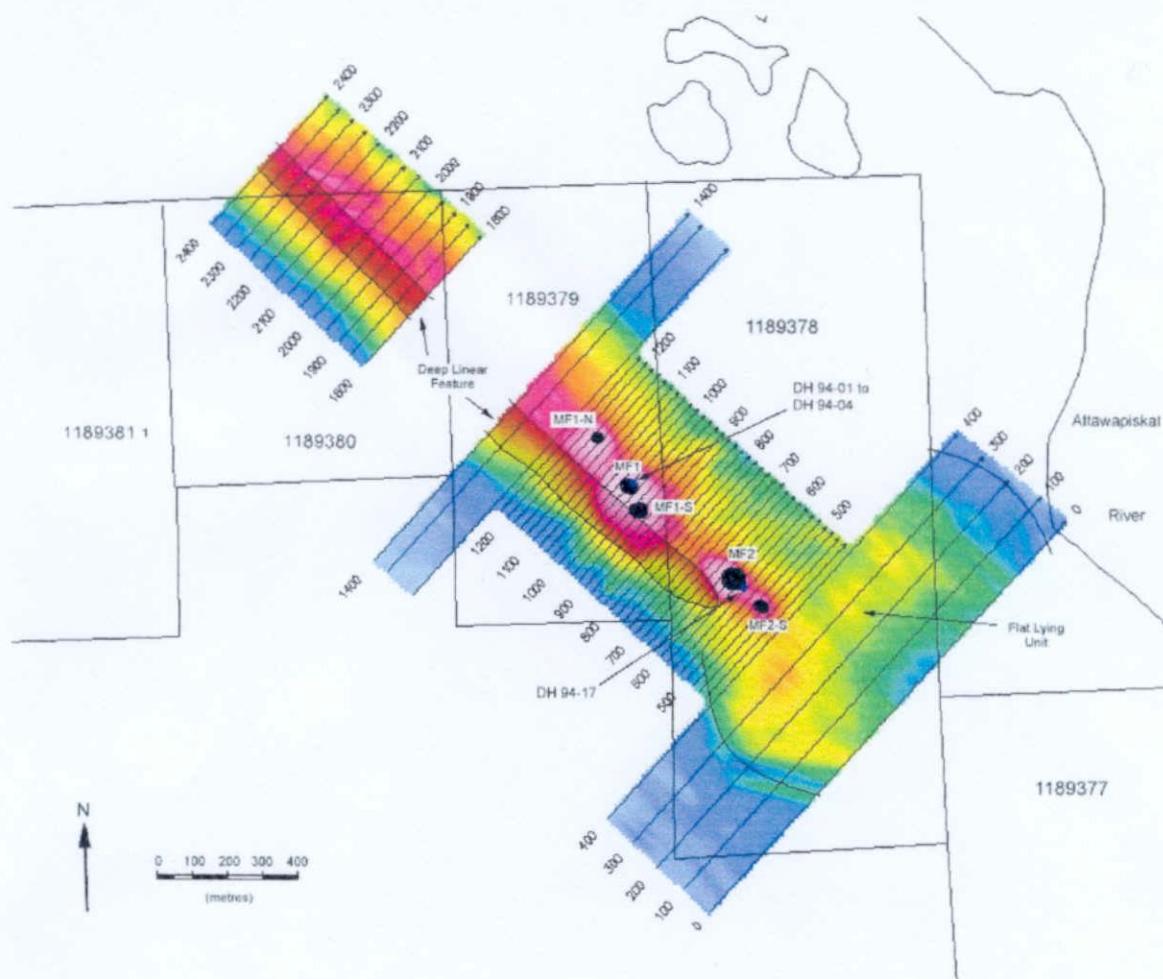

Figure 7 - Interpretation

The MacFadyen 1 and 2 anomalies are associated with drill tested kimberlite pipes. They are presumed to be ovoid in shape with their dimension in a southwest-northeast direction determined by the modeled width and their dimension in the northwest-southeast direction estimated from the indications of significant end-effect. Their overall interpreted properties are summarized in the following table.

Kimberlite	Width(sw-ne)	Width(se-nw)	Depth(m)	Dip(from ne)	Susc(emu)
MF1-s	50	50	95	90	0.0037
MF1	40	50	42	110	0.0043
MF1-n	35	35	45	105	0.0022
MF2-s	35	50	50	75	0.0017
MF2	70	70	40	90	0.0014

Table 5 - Interpretation Summary for Kimberlite Pipes

With the exception of MF1-s, the depths are all close to 40 metres and it is likely that the kimberlite comes to the surface comes to the top of the Paleozoic surface, at the base of the glacial cover. In the case of MF1-s, it is possible that the intrusive has not fully penetrated the Paleozoic but more likely that a less magnetic crater facies and/or locally thicker glacial cover is the cause of the greater depth. The bodies are sufficiently close together that they may simply represent a complex surface shape for a single intrusive or they may be multiple surface vents for a common root system. The possibility of separate events of different age is also possible; the most likely candidate for such a possibility is MF1-n which has the greatest contrast in susceptibility or MF1-s which is distinctive in terms of apparent depth.

The underlying linear anomaly is depicted on the interpretation map. The modeled depth of 275 to 300 metres is considered reasonable for the Archean surface in the area. The 100 metre width, established for the second pass modelling, is considered reasonable but arbitrary. It is possible that the geologic source is a dyke that is only a few metres thick but with higher susceptibility or the source is a wider or banded formation of lower susceptibility. The modeled susceptibility of 0.005 emu is slightly higher than that of the MF1 pipe and about three times greater than that of MF2. If the linear source were kimberlitic with the magnetic susceptibility of MF1 its implied width would be about 80 metres or about 30 metres if the susceptibility of MF2 is considered. Widths of 30 to 80 metres are not typical for kimberlite dykes but not out of the question.

The interpreted flat lying magnetic unit at the southeast end of the survey is of potential kimberlite significance. The first pass model results suggest a flat lying source at a depth of about 250 metres with a vertical thickness of about 40 metres. Physically this would represent a magnetic source, 40 metres thick, lying on or just above a depth of 290 metres. Geologically this could be indicative of a local basement high, rising 40 metres above the surrounding basement surface at a depth of 290 metres. Alternatively it could represent a sill of 40 metre thickness on or slightly above the Archean basement. The modelled susceptibility of 0.0045 emu is close to that of the MF1 kimberlite, a factor that adds further support to the kimberlite sill concept.

Recommendations

The interpreted MF1-s, MF1-n and MF2-s magnetic anomalies definitely warrant drill testing. If they do not represent fully independent kimberlite intrusives they are at least indicative of zones within a pipe that might have different rock properties and hence different diamond grades.

The deeper magnetic features may or may not be of kimberlitic composition. The location of both the linear and sill like feature, close to confirmed kimberlites is favourable. The modeled depths for the linear and sill or basement high are comparatively consistent and in line with depth expectations for the Archean surface. Also, the apparent susceptibilities are reasonably in line with those of the kimberlite pipes. The strongest interpretive factor against a kimberlite source is the implied width of the linear 30-80 metres or vertical thickness of the sill, 40 metres; dimensions greater than expected for most kimberlite dykes and sills. Conversely, if proven to be kimberlite, the larger dimensions would add to their possible economic potential and justify a drill test.

Dear Sir or Madam

Subject: Approval of Assessment Work

We have approved your Assessment Work Submission with the above noted Transaction Number(s). The attached Work Report Summary indicates the results of the approval.

At the discretion of the Ministry, the assessment work performed on the mining lands noted in this work report may be subject to inspection and/or investigation at any time.

If you have any question regarding this correspondence, please contact STEVEN BENETEAU by email at steve.beneteau@ndm.gov.on.ca or by phone at (705) 670-5855.

Yours Sincerely,

A handwritten signature in black ink, appearing to read "Roy Spooner".

Roy Spooner
Acting Senior Manager, Mining Lands Section

Cc: Resident Geologist
