Nabish Lake Property

Contact Bay Area (G-2579)

Kenora District of Northwestern, Ontario

Summary of 1991 Exploration Activities

March, 1991

William C. Yeomans

DMIP 90- 177

#### SUMMARY

This report describes the results of preliminary geophysical and diamond drilling campaigns which were completed during January and February of 1991, on the Contact Bay property. This property consists of forty-two (42) claims which are located twenty kilometers south-southwest of the town of Dryden, in northwestern Ontario.

Samples taken from a surface showing, discovered in 1990 by Messrs. A. Glatz and A. Kozowy, assayed up to 6.5% Cu and 3.5% Ni, with significant platinum and palladium values. Line-cutting, ground geophysics and a 2,000 foot diamond drilling program indicated that nickel-copper mineralization on the Contact Bay property is limited in continuity at depth. The small lense of remobilized mineralization on surface appears to be fracturecontrolled, hosted within a guartz-diorite breccia. Significant drill hole intersections included 0.91% Ni with 0.52% Cu over 1.52 m from a depth of 1.40 m to 2.92 m, and 0.62% Ni with 0.39% Cu over 1.28 m from a depth of 5.00 m to 6.28 m in hole CB-91-01. These values were obtained under the main trench. A vertical hole intersected 0.53% Ni over 0.65 m from a depth of 4.12 m to 4.77 m in drill hole CB-91-05. Five other drill holes returned no significant base metal values. It is recommended that the trench area be washed and mapped in detail. Pending results of detailed mapping and prospecting, selected areas could be tested with an I.P. survey.

#### **1.0 INTRODUCTION**

During December of 1990, Messrs. Glatz and Kozowy of Dryden, Ontario, contacted Société Minière Mimiska Inc. in Thunder Bay, Ontario, concerning a nickel-copper discovery near Nabish Lake, located 20 kilometers south-southwest of Dryden, Ontario. Surface sampling and examination of available VLF-EM-16 and magnetic data resulted with Mimiska optioning the ground late in December of 1990. This report describes the results of subsequent geophysics surveys and a two thousand foot drilling program.

Société Minière Mimiska Inc. can earn a 100% interest in the property by making payments which total \$ 93,000 over four years. A list of claims is presented in Appendix A.

2.0 PROPERTY LOCATION AND ACCESS

The Nabish Lake property is accessible by driving 17 km south from Dryden, Ontario, along highway 594 to the Old Century Road. The Old Century road is followed southwest to the Nabish Lake road. The Nabish Lake road is a seasonal access route which is followed west for a distance of six (6) kilometers to the main showing.

Two separate grids were established on the claim block. The western grid has a north-south oriented base line which extends southward from the Nabish Lake road to the southern limit of the property. East-west lines were also established every 100 m. A total of 6 kilometers of line were cut on this grid.

.

\_\_\_\_

A second grid was completed over Nabish Lake. The base line transected the centre of Nabish Lake at an orientation of N319°E. Cross-lines were established on the ice with a line-spacing of 100 meters. Two tie lines were also cut. A total of 15 km of line was cut on the second grid. A property location map is indicated in Figure 1, while Figure 2 indicates the location of the 42 claim block.

3.0 PREVIOUS WORK

Copper-nickel mineralization in the Dryden area was initially documented by Parsons (1911) at Meridian Bay, located at the south end of Eagle Lake. The Kenbridge Nickel deposit was discovered in 1936. This deposit is situated 24 km, southwest of Muskeg Bay, from Eagle Lake.

Past exploration work by mining companies on the present claim block included Cooper (1962), The Mining Corporation (1968), Hollinger (1969), Lynx (1970) and more recently by Kozowy and Glatz (1989) and Falconbridge (1990). A GSC aeromagnetic map for the Nabish Lake area was initially presented on Map 1154G in 1960. This survey was reflown in 1986 and presented on OGS Map 80971, utilizing the Geoterrex Geotem airborne EM system.

Hollinger (1969) and Lynx (1970) completed ground geophysics surveys and diamond drilling in the vicinity of the main showing. No economic base metal intersections were obtained during these programs. Falconbridge (1990) completed Max-Min and magnetic surveys over the main showing. These surveys did not identify any favourable base metal targets.

Société Minière Mimiska Inc. completed detailed total field magnetic and VLF-EM-16 surveys as well as limited Max-Min and vertical loop programs over the two established grids during February of 1991. These surveys were followed by a 2,000 foot diamond drilling program which tested targets on the two grids.

4.0 REGIONAL GEOLOGY

The Dryden area is situated within the western portion of the Wabigoon Subprovince, and is composed of Archaean volcanic and metasedimentary rocks which have been intruded by granitoid rocks. Some of the granitic intrusions attain batholithic dimensions, causing segmentation of the volcanic and sedimentary rocks into individual belts. The Wabigoon Subprovince is bounded to the north by the English River Subprovince, a gneissic terrain, and to the south by the Quetico Subprovince (Figure 3). Blackburn et al. (1985) developed a tectonic model which basically identifies each of the Subprovinces as being accretionery wedges in an island arc setting.

Figure 3. Simplified regional geology of northwestern Ontario (Modified from Blackburn et. al., 1985) The margins of the Subprovinces are generally oriented eastwest, and characteristically have major breaks or fault zones developed along them. Within the central portions of these belts, high strain zones occur around margins and between granitic complexes.

The property described in this report occurs within a mafic to ultramafic series of intrusive rocks located proximal to the border of the Atikwa batholith. Other copper-nickel occurences in the region occur in this setting.

The stratigraphic nomenclature for the area was described by Moorehouse (1939). Table 1 is a Table of Formations for the area of interest.

#### TABLE 1 - TABLE OF FORMATIONS (From Moorehouse, 1939)

OUATERNARY Pleistocene: Varved lake clays, till, sand and gravel. PRE-CAMBRIAN Diabase dikes. Keweenawan: Granitic intrusives: Pegmatitic granite; granodiorite, quartz diorite, granite gneiss. Algoman(?): Hybrid intrusives: Diorites, amphibolites intrusive into the Keewatin and cut by granite. Haileyburian(?): Basic intrusives: Norite, diabase, gabbro, anorthosite, and transitional phases; diorite; sheared, chloritized, and silicified equivalents; some granites. Timiskaming(?): Sedimentary series: Greywacke and paragneiss with minor amounts of slate and quartzite; iron formation. Keewatin: Volcanic complex: Flows of basalt, andesite, dacite and rhyolite and their pyroclastic and altered equivalents; associated porphyry dikes, possibly, in part,

of Algoman age.

#### 5.0 PROPERTY GEOLOGY

Société Minière Mimiska Inc. did not map the property, as the ground was optioned in December, 1990. A limited amount of data is available, from drill holes and previous work. The property geology can only be summarized from this data.

The Nabish Lake property contains hybrid diorite and mixed contact phases of amphibolite and other ultramafic rocks which are considered to be Algoman by Moorehouse (1939). These diorites and amphibolites intrude Keewatin intermediate to mafic rocks. The younger Atikwa batholith intruded the mafic to ultramafic rocks and the Keewatin felsic to mafic volcanics.

The ultramafic rocks have a strong aeromagnetic and ground magnetic signature on the claims. Quartz diorite appears to be a border phase to the ultramafic sequence, and this phase is commonly brecciated. The breccia contains angular fragments of Keewatin felsic rocks. The ultramafic rocks have been mapped as gabbro by Cooper (1962). Gabbro was observed with amphibolite and talcchlorite schists during the 1991 drilling campaign. Several of these rock types are highly magnetic, with up to 5% magnetite.

Within the vicinity of the main showing, drilling by Hollinger (1969) and Lynx (1970) intersected amphibolite and feldspar porphyry dikes along with quartz diorite breccia. The zones of brecciation are widespread immediately west of the ultramafic sequence. Brecciation may be structurally controlled. Coppernickel mineralization appears to be spatially associated with the quartz diorite breccia. Drill hole results by Hollinger and Lynx returned uneconomic values.

The main Glatz-Kozowy trench is located at L7+10S, 15 m east of Base Line 0+00, and is known as Trench 1. It is oriented approximately N025°E and is 5.5 m in length. The second trench is located 4 m north of the northern limit of Trench 1. This trench terminates along line 7+00S, 15.5 m east of Base Line 0+00. The total length of Trench 2 is 7 m, and it is oriented north-south. Outcrops of rusted diorite and quartz diorite breccia are present between Trenches 1 and 2 and Base Line 0+00.

Spectacular pyrrhotite-chalcopyrite mineralization is present at Trench 1. Up to 25% chalcopyrite and 60% pyrrhotite was observed and sampled. The sulfides appear to be remobilized. The host diorite may have been totally replaces. Semi-massive sulfide containing blue quartz eyes and altered chloritic wallrock was observed in Trench 1. It was not possible to obtain any detailed structural data due to the amount of snow and blast debris which filled the trench. The width of the zone appears to be 1.0 m to 1.5 m, and strikes roughly N025°E. The mineralization occurs as a

small lense with limited strike potential. A 1:5000 scale compilation map for the property indicates the location of previous drilling, geophysical anomalies and geology (Back Pocket). The trenches are indicated on a 1:500 scale map. Complete rock descriptions for areas drilled are available in the drill logs (Appendix B).

6.0 STRUCTURAL GEOLOGY

The regional schistosity is variable within the Nabish Lake mafic to ultramafic complex, ranging from a northwest to northeast direction. Major fault zones trend N025°E and N325°E. These sharply defined lineaments are recognizable on regional maps and air photos.

The N025°E lineaments may have been responsible for an event which allowed the emplacement of quartz diorite breccia and the remobilization of base metals. A large scale lineament oriented N025°E is situated 40 m east of the main showing. The proximity of this structure to mineralization suggests that it may have been a controlling factor during the mineralizing event. Most of the small showings and sporadic geophysical anomalies are oriented parallel to this feature. Mapping and prospecting would be required to ascertain the importance of this lineament. Drilling indicated that some of these fault structures contain hydrous mineral assemblages and fault gouge with elevated nickel and palladium values (CB-91-06).

#### 7.0 ECONOMIC GEOLOGY

Copper-nickel values are plotted on the detailed map of the main showing. Grab samples returned up to 6.5% Cu and 3.5% Ni. Platinum and palladium values ranged up to 280 ppb. Drill hole results proved that these high values do not continue for any significant depth. Drill hole CB-91-01 intersected 0.91% Ni with 0.52% Cu over 1.52 m from a depth of 1.40 m to 2.92 m, and 0.62% Ni with 0.39% Cu over 1.28 m from a depth of 5.00 m to 6.28 m. These values were intersected at a shallow depth directly under Trench 1. Drill hole CB-91-05 was drilled vertically in Trench 1 to test the mineralization at depth. Weak mineralization was obtained at the top of the hole, including 0.53% Ni over 0.65 m from a depth of 4.12 m to 4.77 m. It was noted that hydrous alteration within the breccia had taken place, as chloritic rims around fragments appeared to be biotitized.

Biotitized fault zones containing elevated Ni and Pd values were intersected within the ultramafic complex near the northern limit of Nabish Lake. These magnetite rich sections contain up to 1,140 ppm Ni and 140 ppb Pd. Drill holes CB-91-02, 03 and 04 did not obtain any significant values. The drill hole results from the 1991 program indicated the limited potential of the main zone. However other geophysically defined targets on the property remain untested. Sample descriptions and assay values from the main showing are presented in Appendix C.

#### 8.0 RESULTS OF GEOPHYSICS SURVEYS

8.1 TOTAL FIELD MAGNETIC SURVEY

During the fall of 1990, Mr. A. Glatz completed a total field magnetic survey utilizing a Scintrex MP-2 Proton procession magnetometer over claims K1133302 and K1133303, on the western grid.

The main showing corresponds to a magnetic low with an adjacent magnetic high. The magnetic high is caused by pyrrhotite mineralization. The magnetic high values drop off substantially to the north and south of Line 7+00S, indicating the limited strike length potential of the main showing.

During January and February of 1991, Mr. A. Glatz completed a magnetic survey over east-west lines south of the showing and over the Nabish Lake grid. No significant magnetic anomalies were identified on the western grid south of the main showing (Map 3, Back Pocket).

The Nabish Lake survey (Map 3) identified a magnetite rich unit that trends approximatively N330°E, parallel with the base line. Drilling indicated that the high magnetic values were caused by disseminated magnetite. Several N025°E fault zones cross-cut this unit, causing a segmented appearance as a result of magnetite destruction within biotitized shears. One isolated magnetic high occurs near the southwest corner of Nabish Lake. The cause of the high magnetism is suspected to be magnetite mineralization. The magnetometer survey proved to be the most useful tool for outlining areas of potential Cu-Ni mineralization on the property.

8.2 VLF-EM-16 SURVEY

During the fall of 1990, Mr. A. Glatz completed a VLF-EM-16 survey (NSS Annapolis, Maryland) over claims K1133302 and K1133303 on the western grid. Conductors A, B, C and D were identified, with Conductor A corresponding to the main showing. Conductors A and B were drilled and returned negligible results. Conductor A is caused by sporadic mineralization, while Conductor B is suspected to be caused by an overburden response. Conductors C and D do not have an associated magnetic anomaly, suggesting that pyrrhotite is absent. It was noted during the drilling campaign that the distance between pickets on the Glatz-Kozowy grid was poorly rechained. It appears that the grid was originally picketed on 25 meter stations. Messrs. Glatz and Kozowy relabelled the 25 meter stations as 100 foot stations, introducing an error of 5.48 m between each consecutive station. The plotted data by Glatz is suspected to be innaccurate.

This problem did not occur on Mimiska's winter grid, cut south of claims K1133302 and K1133303, or on the Nabish Lake grid. A. Glatz was hired to complete VLF-EM-16 surveys during February, 1991. No significant VLF-EM-16 responses were identified. Weak VLF-EM-16 responses on the grids are considered to be caused by lake bottom clays or topographic effects. Approximately 25 m of clay and muddy glacial outwash filled the Nabish Lake basin. The Annapolis NSS Maryland transmitter station was used for this survey. The VLF-EM-16 survey did not prove to be a useful exploration tool on the Nabish Lake grid.

#### 8.3 VERTICAL LOOP SURVEY

The vertical loop survey was conducted over several lines on the Nabish Lake grid. The frequency utilized was 930 Hz and the instrument model was an Inco Mark IV unit. The survey was completed in late January by D. Macheachern. The vertical loop data is presented at a scale of 1:2500 (back pocket). The profiles indicate that weak cross-overs exist under the lake. Several of the anomalies may be related to geological contacts between magnetic and nonmagnetic rock types.

8.4 HORIZONTAL LOOP SURVEY

A limited amount of H.E.M., utilizing an Apex instrument and three frequencies (444 Hz, 1777 Hz and 3555 Hz) with a 400' cable was completed on the Nabish Lake grid. The results were generally flat, with a weak anomaly at 1+75E on line 8+00N. The in-phase responded with positive values over magnetite-rich rock near BLO on line 8+00N. This data is presented on Map 4, located in the back pocket of this report.

#### 9.0 SUMMARY OF DIAMOND DRILLING

Seven diamond drill holes, totalling 609.6 m were completed during a preliminary campaign in February, 1991. Individual drill logs are presented in Appendix B. All of the drill holes are plotted on 1:5000 scale maps, and drill sections are plotted at a scale of 1:500. These are located in the back pocket. Significant values intersected in drill holes CB-91-01 and CB-91-05 were discussed in the Economic Geology chapter. Drill holes CB-91-02, 03, 04, 06 and 07 did not return any significant values. A Summary Table of important information concerning each drill hole is presented in Table 2.

### TABLE 2 - DRILL HOLE SUMMARY

DRILL HOLE	COORDINATES (metric)	AZIMUTH	DIP	LENGTH (m)	OBJECTIVES	RESULTS
СВ-91-01	L7+17.5S 0+12.4E	N030°E	-50°	60.96m	Western Grid Trench 1	0.91% Ni with 0.52% Cu over 1.52m from a depth of 1.40m to 2.92m

...

#### 10.0 CONCLUSIONS AND RECOMMENDATIONS

The main showing on the Nabish Lake property is a remobilized lense of copper-nickel mineralization which does not have continuity at depth. The mineralization appears to be fracture controlled and hosted within quartz diorite breccia. Subeconomic values were obtained from the drilling campaign.

It is recommended that the main showing be completely stripped, washed, and mapped in detail. Additional mapping and prospecting could be carried out over areas of potential interest. If no significant showings or encouragement were obtained from this small program, the property should be abandoned.

Dear Sir:

#### Re: ALEX GLATZ and SOCIETE MINIERE MIMISKA INC. Our File No. 15-189

Our client, Alex Glatz, performed prospecting work for Societe Miniere Mimiska inc. on certain claims in the Nabish Lake area of Ontario.

I attach copy of our client's account dated February 14th, 1991. The entire balance of \$3,042.81 is outstanding.

Our client understands that Societe Miniere Mimiska Inc. has applied to your office for an O.M.I.P. grant covering a portion of the exploration costs incurred. Our client does not wish these monies to be released directly to Societe Miniere Mimiska Inc., but forwarded to him in satisfaction of his account.

Would you please give me a call in this connection and confirm what action our client should take to protect his interest.

Yours truly, MCAULEY & PARTNERS

Peter A. Burns
