SUMMARY

A combined airborne electromagnetic and magnetic survey was executed over 114 claims located in the Six Mile Lake Area of Ontario on behalf of Larchmont Mines Limited. A total of 123 miles of line was flown.

The survey resulted in the location of several isolated mostly broad anomalies. Three conductor intersections revealing a coincident magnetic response can be caused by massive sulphides and have been recommended for geological and geophysical ground follow-up.

REPORT ON AN AIRBORNE GEOPHYSICAL SURVEY SIX MILE LAKE AREA, ONTARIO ON BEHALF OF LARCHMONT MINES LIMITED

INTRODUCTION

During the period April 29th to May 2nd, 1971, an airborne geophysical survey was undertaken by Seigel Associates Limited over two blocs of claims located in the Six Mile Lake area, Ontario (see fig. 1 on the scale of 1:250,000). The first bloc (marked A) comprises 30 claims, the second bloc (marked B) comprises 84 claims (see Table 1). The survey was on behalf of Larchmont Mines Limited. A total of 34 miles was flown over Bloc A and a total of 89 miles over Bloc B (see Plate 1, claim map on the scale of 1" = 1320').

The airborne survey included electromagnetic and magnetic measurements. Geophysical equipment used for these measurements was, respectively, a Scintrex Rio-Mullard type in-phase and out-of-phase electromagnetic system operating at 320 cycles per second and a Scintrex MAP-2 nuclear precession magnetometer.

Appendix A attached gives full details of the airborne geophysical equipment and ancillary equipment employed as well as the treatment of data resulting from these surveys. The basic transport vehicle employed during the survey was a De Havilland Otter aircraft (CF-IUZ) owned by Scintrex Limited, Toronto.

In-flight navigation and flight path recovery were based on a mosaic with a scale of 1"=1320'. The survey line spacing was 400 feet, the line or direction being approximately north - south.

The survey was flown at an average airspeed of 90 miles per hour and at an average altitude of 175 feet.

The purpose of the electromagnetic survey was to map the distribution of subsurface conducting systems within the survey area. The magnetometor results are presented in contour form which enable an interpretation in terms of rock types and geological structures. The magnetic data are also used in direct correlation with the electromagnetic results. PRESENTATION OF DATA

The results of the geophysical survey are presented on Plates 1 and 2 each of which are on the scale 1"=1320'. Plate 1 shows the electromagnetic results together with the flight lines and Plate 2 shows the magnetic results in contour form at a 10 gamma interval.

The peak location of the electromagnetic anomalies is shown on the Plate 1 by a circle in the appropriate location. In the case of broad conductors, or closely spaced multiple conducting zones, there may be more than one peak. In this event all major peaks are shown. The conductor half width, indicated on the plan by an open bar, is the distance between the points of half the maximum conductor disturbance.

The in-phase and out-of-phase amplitudes are scaled from the original traces and are noted in parts per million opposite the peak location. A conductor peak with apparent direct magnetic correlation is indicated by a double concentric circle.

The original geophysical traces are on the following scales:

magnetometer

Edin Recorder (from top to bottom of chart)

1st and 2nd channel not used

4th	channel	electronic	noise
		indicator	

5th channel

3rd channel

- 6th channel
- 7th channel electromagnetometer 30 ppm/mm (in-phase)

altimeter

electromagnetic (out-of-phase)

8th channel accelerometer

9th channel fiducial marker

Anadex Recorder

The total magnetic field values were recorded in digital form on a paper print-out, together with the fiducial numbers as well.

25 gammas/mm

Logarithmic

30 ppm/mm

<u>, 3</u>

DISCUSSION OF RESULTS

The airborne electromagnetic survey resulted in the location of several isolated often broad, multiple conductors. Even though the anomalies are isolated, a certain trend in the conduction is shown between lines 52S and 83N south of the tie line in $\operatorname{Bloc}_{\Omega}^{K}$ B. The conductor amplitudes exhibit a spectrum of responses and all the anomalies are graded in the second and third category.

One of the most important criteria in the evaluation of the electromagnetic anomalies is the in-phase over out-ofphase ratio. In general, highly conducting bodies, such as massive sulphides or graphite and sea water have high ratios, however, most overburden will have lower fatios. In areas where there is clear differentiation in conductivity between targets of economic interest and other possible conductors the ratio is a diagnostic feature. In some areas there is an overlap of conductivity ranges and then the ratio cannot be too rigidly relied upon. Another important criteria is the magnetic coincidence. A conducting body which shows a magnetic correlation is more likely to be a sulphide body than one that is nonmagnetic. Still another important criteria is the strike length. Most producing base metal mines have ore bodies of only a relatively short strike extent and most ore bodies give only a single or double line anomaly during the course of any

reconnaissance airborne survey. For this reason single line anomalies cannot be overlooked but neither must long conducting zones be neglected as some ore bodies are known to occur along extensive marker horizons. (e.g. Thompson area),

All but three electromagnetic anomalies revealed during the present survey likely belong to the group of near surface conductors of horizontal extend.

Three anomalies can be classified in the group of steeply dipping tabular conductors and are threefore of interest. These are: Intersection A and B on line 16 and intersection A on line 58. These reveal very weak responses, however, they all show magnetic correlation.

The magnetic contour plan shows a moderate relief combined with a general east-west trend.

Magnetic highs "A" and "B" (up to 100 gammas) are accompanied by a very weak electromagnetic distortion pattern.

Magnetic high "C" is striking in east-northeast to west-southwest direction and reveals a 70 gammas peak amplitude. Magnetic highs A, B and C likely reflect more basic horizons, possible basic intrusive plugs in the meta volcanic/sedimentary sequence.

Magnetic high "D" runs in an east-west direction. It is associated with a metagabbro intrusive (Map 2169 on the scale of 1" = 4 miles). Magnetic high "E" runs in a northwest-southeast direction. Magnetic relief is up to 250 gammas. It probably reflects a gabbroic dyke parallel to the series of granitic dykes mapped in this area. Several small faults in a northwest and northeast direction are shown on the magnetic plan.

CONCLUSIONS AND RECOMMENDATIONS

During the present survey several isolated but open broad conductors were revealed. Investigation of the electromagnetic anomalies should be limited only to the anomalies A and B on line 16 (Bloc A) and to the anomalay A on the line 58 (Bloc P). These intersections reveal a coincident magnetic high and possible reflect massive sulphides. For examination of selected targets on the ground and for the determination of their precise location the combination of surveys on small grids, comprising geological mapping magnetic and electromagnetic measurements, is recommended. These small grids should consist of a baseline of approximately 2000 feet long and 6 lines perpendicular to the baseline at 400 feet spacing having a length of 1000 feet on either side. It is recommended to execute Turam electromagnetic measurements.

Respectfully submitted,

Klemant Dande

Jan Klein,

Geophysicist.

APPENDIX A

SURVEY EQUIPMENT AND PROCEDURES

Electromagnetic System - Scintrex-Rio Mullard

The aircraft used in the present survey is a De Havilland Otter DHC-3 with Canadian registration CF-IUZ. This aircraft is a single engine, slow speed high performance type with a gross weight of 8000 lbs. It may be equipped with wheels, skis or floats as required.

The aircrew consists of pilot, navigator and equipment operator. The aircraft is flown along the proposed lines at an altitude of 150-200 feet using mosaics for navigation.

The operator records in the flight log, the line numbers, direction of flight, duration of flight and starting and finishing fiducial numbers.

The Rio-Mullard Electromagnetic System measures in-phase and out-of-phase components of the secondary field at a frequency of 320 Hz.

A transmitter generates a closely controlled sine wave of 320 Hz which is amplified and fed to a transmitting coil mounted on the starboard wing-tip. This coil is iron cored, has vertical windings and is mounted with its axis in the direction of flight. The circulating coil power is 7500 volt-amperes.

A receiving coil is mounted on the port wing, coplanar with, and 62 feet from the transmitting coil. The voltage developed in the receiver coil due to the transmitted field is 100 millivolts. In the absence of external conductors, this voltage is cancelled by a reference voltage derived directly from the transmitter voltage.

When the aircraft comes within the range of a conductor, the normal (or primary) field is changed by a secondary field and the resultant voltage at the receiver coil is amplified and passed on to the EM receiver in the aircraft. This signal is filtered and split into one component in-phase and one component out-of-phase with reference to the transmitter voltage. The signals are then passed through phase -sensitive detectors where their amplitudes may be read on meters, or recorded on a chart. A system of calibration is included so that the amplitude of responses (anomalies) may be determined in "parts per million" of the primary receiver coil voltage prior to cancellation. The noise level of the system due to movement of the metal aircraft within the EM field is normally 50 parts per million less. Significant conductors depending on distance and size will produce anomalies of more than 50 parts per million. Calibration marks are shown on the recorder chart and are generally of the order of 1 cm for 300 parts per million.

The reference or "zero" level for each EM trace is an arbitrary one and is obtained empirically from the regional level of each trace. These levels may drift very slowly during a flight because of temperature changes. These drifts are very gradual and are readily distinguishable from much quicker, local changes due to conductors of a geologic origin. Similarly, severe turbulence effects sometimes introduce low-order, primarily in-phase disturbances which are of such short period that they may also readily be distinguished from the effects of geologic conductors.

p 2

Man-made disturbances are often to be seen, including power lines, pipe lines, metal fences, railways, etc. The former are generally recognizable as such because they usually show through as cyclic noise of irregular shape and phase relationship. Non-energized, grounded power lines (e.g. 3 phase systems) may also give rise to proper conductor indications, however. Such indications, as well as those from pipe lines and metal fences, etc. are usually of short duration and can be distinguished from proper geologic sources except for very narrow, near-surface lenses. In some instances ground investigation may be necessary in order to resolve the ambiguity of possible source. Whereas the airborne geophysical crew attempts to note visible man-made conductors of the above types, the ground moves by so rapidly at the low flight elevation employed that 100% recognition of such sources cannot be expected from the air.

The normal terrain clearance of the aircraft is 150-250 ft. depending on the surface topography and tree cover, etc. The established useful depth of detection of the system for moderate-to-large conducting bodies is about 400 ft. sub-aircraft under conditions of low extraneous geolgoic noise, i.e. where the general level of conductivity of the overburden and rock types of the area is low. The useful depth of detection of the system is therefore, between 150 ft. and 250 ft. beneath the ground surface under these conditions.

Interpretation of Results: The EM records are interpreted to determine the presence of conducting bodies and to obtain some information relating to their character. The intervalometer time marks (see below) are synchronized with the positioning camera film strip (also see below) and thereby permit the relating of the conductors with appropriate ground locations. The altimeter data (see below) indicate, for each conductor, what the terrain clearance was at the time of detection.

A plan is prepared, either using a subdued photo-mosaic ('greyflex'') or an overlay from a mosaic or topographic plan as base. The flight path of each survey line is obtained by means of ''tie points'', which are features on the mosaic or topographic plan which are also recognizable on the positioning camera film. The flight path is interpolated between these tie points. Any anomalies noted are listed in the report, indicating their position, amplitudes, magnetic correlation, if any, relative anomaly rating, and comments which may be of significance.

The anomalies are then plotted on a base map in coded form, according to a legend shown on the base map. Anomaly groups which reflect probable ground conductors are circled and numbered. These are described and discussed in the report in the context of their geophysical and where possible, geological significance.

For each conductor the following quantities are measured and recorded:

A. <u>Half width</u>. This is the distance between the points of half the maximum conductor disturbance. For a very thin, steeply dipping body or pipe line, etc., the half width will be about 1.6 times its depth below the aircraft. If the bird is at a mean conductor clearance of 150 feet the half width would be about 250 feet. Larger half widths reflect either more deeply buried or more likely, thicker conductors.

B. <u>Peak Location</u>. The in-phase conductor peak location is shown on the plan by a circle in the appropriate location. In the case of broad conductors or closely spaced multiple conductor zones there may be more than one peak, in which event all major peaks are shown. If a conductor is of short half width there may be no room for a half width bar and only the peak circle will be shown. A conductor which is likely manmade will be indicated by an X rather than by a circle.

C. <u>In-Phase and Out-of-Phase Amplitudes</u>. These amplitudes are scaled from the EM traces and noted in parts per million. On the flight plan, opposite each peak location (circle) will be given the peak inphase and out-of-phase amplitudes (see below).

D. <u>Conductor Coding.</u> Conductor intersections are graded in electrical categories 1, 2, and 3, based on the in-phase amplitude but taking into account the terrain clearance. For tabular bodies such as sheet-like ore deposits, strata bound conductors and overburden, their response drops off almost in accordance with the inverse cube power of the elevation. Assuming an average 50 feet of overburden, a category 1 conductor has a peak in-phase response equivalent to 200 ppm or over at 150 feet aircraft-terrain clearance. A category 2 conductor has a peak in-phase response under similar conditions of between 75 ppm and 200 ppm. A category 3 conductor has an equivalent peak in-phase response of less than 75 ppm.

The respective peak circles are shaded to reflect their electrical category, with category 1 fully shaded, category 2 half shaded and category 3 unshaded.

3

The ratio of peak in-phase over peak out-of-phase amplitudes is indicative of a conductivity-size factor for the conductor. Generally, high conducting bodies such as massive sulphides or graphite and seawater, etc., have ratios of 1 or over. Moderate conductivity-size bodies will have ratios between.5 and 1. Poor conductivity bodies (e.g. most overburden and some sulphide and graphitic zones) will have ratios of less than .5. In areas where there is a clear differentiation in conductivity between the targets of potential economic interest and other possible conductors, the ratio is a diagnostic feature. In some areas, however, there is an overlap of conductivity ranges and then the matio cannot be too rigidly relied upon.

Where magnetic data is available, preferably from a coincident recording magnetometer, any correlating magnetic activity will be noted for the pertinent conductor peak. A conductor peak with apparently direct magnetic correlation will be indicated by a double concentric circle. Although a conducting body which is appreciably magnetic is more likely to be a sulphide body than one which is non-magnetic, there are many very important base metal ore bodies which are quite non-magnetic.

°<u>4</u>

<u>Altimeter</u>: The altitude of the aircraft is monitored to an accuracy of \pm 10 feet using a Bonzer Model TRN-70 radio altimeter at 1600 MHz. The altimeter results are recorded permanently on one channel of the eight channel recorder.

<u>Camera</u>: The path recovery camera is an Automax 35 mm unit with a special wide angle lens. Its operation is controlled by an intervalometer whereby one frame is triggered for each fiducial number. The camera is thus synchronized with the Edin and Moseley recorders.

Intervalometer: The intervalometer is a Scintrex Model IV-1 Solid State unit with variable time interval from 0.5 to 2 seconds. It operates the marker pens on the two recorders, the frame camera, and a rotary counter. The repetition rate is set so that the camera frames produce only slight overlap. This is approximately once per second.

<u>Recorders:</u> The Edin recorder is an eight-channel ink recorder type 8001. The galvanometer sensitivities are 12 volts full scale into 1350 ohms. The scale on each channel is four centimetres in width and the normal recording speed is 2 millimetres per second. The horizontal scale on the chart is thus roughly 4" per mile of traverse.

The Moseley recorder is a single channel ink recorder type 680. This recorder is used to register the magnetic information.

<u>Reduction of Data:</u> Upon completion of a flight, the film is developed and the actual path of the aircraft is plotted on a base map. This is accomplished by comparing film points with the base map planimetry. For any given point, the appropriate fiducial number is placed on the base map (or photo laydown). The actual flight path is produced by joining the fiducial points.

Where field results are desired, anomalies are chosen and are assigned appropriate fiducial numbers. The anomalies are then transferred to their correct position on the base map.

Flight lines and fiducial numbers are finally presented on a greyflex which is made using the photo mosaic as a base.

In the case of EM or radiometric results the anomalies are plotted on the greyflex as boxes with symbols representing anomaly grade or amplitude (as noted on the legend accompanying each map). Anomaly "systems" are then outlined at which stage a geophysical interpretation can be made.

MAP-2 Proton-Precession Magnetometer

The MAP-2 is a lightweight, one gamma airborne proton-precession magnetometer with a range of 20,000 to 100,000 gammas and an automatic five digit visual display. This new instrument has several significant advantages over other instruments of this type besides its compact size and light weight.

One of its most interesting features is that, unlike other airborne magnetometers which have to be switched manually from one narrow (usually 4000-6000 gammas) range to another, the MAP-2 tracks automatically over its full 80,000 gamma range.

This advantage is particularly significant in surveys flown at low terrain clearances in areas of high magnetic relief, conditions which are common in mineral prospecting.

The instrument is of compact modular design $(\frac{1}{2}$ standard rack size) and has both digital and analogue outputs. The analogue outputs are either 100 or 1000 gammas full scale, with automatic stepping. During each step, an indication of the new stepping level is recorded, providing a permanent reference identifying each step.

The measuring sequence can either be sequentially triggered internally through its own programmer or initiated by a suitable command pulse.

In addition while on internal triggering the instrument provides an external output command pulse enabling other instrumentation to be synchronized with the magnetometer.

The MAP-2 has an unusually wide temperature range, $+50^{\circ}$ C to -30° C, to permit operation in conditions varying from tropical to arctic without any loss of accuracy.

Specifications:

Range:

20 - 100,000 gammas (world-wide) continuous range (automatic tracking).

Sensitivity: + 1 gamma (fully automatic)

Accuracy: ± 1 gamma

Sampling Rate:

Automatic standard 1 second, with provision for external triggering from other equipment with minimum 1 second intervals.

Readout-Visual: Digital Display by 5 incandescent, 7 bar display lights.

Digital Data

Cutput: BDC 1-2-4-8 DTL, TTL Compatible

Analog Data 5 V full scale for 1000 gammas, 100 gammas, 1 gamma Output: resolution

External Trigger: Requirement: +4V to 0 transition (as slave)

Trigger Output: +4V to 0 transition at start of cycle (as master)

Power Requirements:

24-30V DC, 3.2A max.

Temperature Range:

-30 to +50 degrees C

Dimensions and Weights:

Console: $8\frac{1}{2}$ x $5\frac{1}{4}$ x 13" (half rack) $21\frac{1}{2}$ cm x $13\frac{1}{2}$ cm x 33 cm 12 lbs. (5.4 kg)

Tow Bird: 7" x 23" (18 cm x 58 cm) 20 lbs. (9 kg)

CRONE GEOPHYSICS LIMITED

3607 WOLFEDALE ROAD, MISSISSAUGA, ONTARIO, CANADA.

Phone: 270-0096

This is a rugged, simple to operate, ONE MAN EM unit. It can be used without line cutting and is thus ideally suited for GROUND LOCATION OF AIRBORNE CONDUCTORS and the CHECKING OUT OF MINERAL SHOWINGS. This instrument utilizes higher than normal EM frequencies and is capable of detecting DISSEMINATED SULPHIDE DEPOSITS and SMALL SULPHIDE BODIES. It accurately isolates BANDED CONDUCTORS and operates through areas of HIGH HYDRO NOISE. The method is capable of deep penetration but due to the high frequency used its penetration is limited in areas of clay and conductive overburden.

The DIP ANGLE measurement detects a conductor from a considerable distance and is used primarily for locating conductors. The FIELD STRENGTH measurement is used to define the shape and attitude of the conductor.
