## INTRODUCTION

An induced polarization survey was performed over a property owned by **Cameco Gold Inc.** The property is located in Sharron Lake and Zarn Lake townships, Ontario. The I.P. survey was performed in order to detect possible conductive and/or polarizable horizons, to which economic mineralization may be associated.

## PROPERTY, LOCATION AND ACCESS

The property is located approximately 21 km east-north-east of Sioux Lookout, in Sharron Lake and Zarn Lake townships, Ontario. The survey covered claim 1162704 ( $\pm$  252 hectares). The property can be reached using highway 642 east, for  $\pm$  17 km, and a skidoo trail for  $\pm$  15 km, up to Black Lake.

## GEOPHYSICAL WORK

During the period of December 9th to 16th, 1997, an induced polarization survey (7,1 km) was performed on the property. Measures were done in the Time domain, using dipole-dipole configuration and the following separation:  $a = 25$  metres,  $n = 1$  to 6. Iron electrodes were employed at the receiver and at the transmitter. The time constant ( $\tau$ ) was computed.

In general,  $V_p$  were higher than 100 mV. At a few locations however, it decreased to values lower than 10 mV, especially where the overburden is thicker. Electrode resistances are relatively high, due to the presence of outcrops and sandy overburden. The survey had to be suspended before its entire completion because of these hard field conditions. This can be seen on the pseudosections, which appear much noisy.

The grid includes 200 and 100 metre apart  $\pm$  north-west lines.

### DISCUSSION ON THE GEOPHYSICAL METHOD

#### The induced polarization method:

The induced polarization survey consists in introducing an electric current into the ground in the form of a "square wave", by means of two metallic electrodes. Two other electrodes permits the measurement of the current and of the voltage present in the ground during the transmission. The resistivity of the ground is then calculated with these two parameters while the chargeability is measured by observing the decrease of the voltage after the current flow stops. The chargeability is in millivolts/volt (mV/V) or milliseconds, and the resistivity in ohms-metres ( $\Omega \cdot m$ ).

The induced polarization method allows the detection of massive or disseminated sulphide zones which are not necessarily conductive. The chargeability intensity of an anomaly depends mainly on the total surface of the disseminated sulphide grains, their nature, the geometrical shape and the

depth of the sulphide zone as well as the conductivity and the thickness of the overburden.

That means the intensity of an I.P. anomaly varies with the grain size and theoretically, massive sulphide zones give a lower anomaly in chargeability than the same amount of sulphides disseminated. At the limit, if it is completely massive, we do not have a chargeability anomaly. It is almost impossible to interpret which quantity of sulphides is producing the anomaly. However, from previous data known on the property, we may guess the amount of sulphides.

If a weak anomaly of chargeability coincides to a low resistivity associated to a resistivity gradient, this anomaly may be produced by ionic currents. Care should be taken in presence of this phenomenon.

High readings of resistivity normally mean that the bedrock is near the surface. Very often, this is also associated with a higher chargeability reading which is then difficult to say if there is presence of weak disseminated sulphides. High resistivity may also indicate the presence of silicified rocks.

Low readings of resistivity without high chargeability readings normally mean that the current does not reach the bedrock. A greater separation should be used in these areas. However, it may also mean presence of massive sulphides, which may be interpreted by the shape of the anomaly itself.

In other words, an induced polarization survey may sometimes be difficult to interpret (it gives no information about

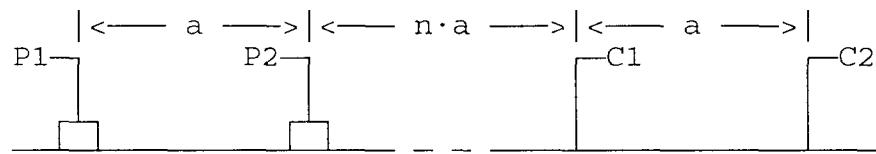

the dip) and it is normally recommended to detail any main anomalies and to interpret them with respect to the geological, topographic and all other pertinent information before proceeding with the drilling.

The readings of the survey are plotted in form of pseudo-sections. Profiles on the pseudosections are computed using Fraser filtering. The anomalies are indicated by appropriate symbolism. The probable location of polarizable or conductive zones is indicated by an axis.

The resistivity was calculated using the following formula:

$$P_a = \pi \cdot n \cdot (n + 1) \cdot (n + 2) \cdot a \cdot V / I \quad \Omega \cdot m$$

Configuration dipole-dipole:

The time constant ( $\tau$ ), expressed in milliseconds, was computed (Johnson, 1984). This parameter is indicative of the shape of the decay curves and has been related to grain size. By definition, it also gives an idea of the quality of the data. When noise was too strong to get a good fit for a particular location, the value -1000 was assigned to that location. The  $\tau$  values appear at the top of the pseudosections.

GEOLOG  
Geological Survey of Canada

## DESCRIPTION AND INTERPRETATION

The induced polarization survey performed over the property, permitted to detect only one well defined anomaly. Some other anomalies, mainly consisting in resistivity lows but also in weak chargeability anomalies, were also interpreted. All are plotted on the pseudosections and on the maps.

The apparent resistivity varies a lot over the grid. Line 8400 E gives a good idea of this variability. At some locations, the resistivity is low but increases from less than  $50 \Omega \cdot m$  on N = 1 to  $\pm 300 - 400 \Omega \cdot m$  on N = 6. This generally indicates the presence of a thicker conductive overburden layer. In general, resistivity lows are interpreted as valleys and/or as fractures in the bedrock, but alteration zones may also produce such features. Higher resistivities are generally interpreted as bedrock uplifts or, for very high resistivities, as outcrops. This may also reflect silicification.

As mentioned before, a dummy value of -1000 ms was assigned to the time constant when the raw data were too noisy. We may say as well that for this particular survey, large time constants (100 s) are more often related to noisy data.

The first priority anomaly P-01 is located on line 87+00 E (station  $\pm 29+70$  N). It is not very strong (2 to 3 mV/V with background values of less than 2 mV/V), but it is well defined. It also correlates to a weak increase in resistivity. The decay curves for this anomaly are relatively clean (at least for the first four separations) and the time constant varies from 10 ms to 300 ms on N = 1 to 4. Based on these parameters, the related mineralization should then be of the "disseminated type", with fine grain material.

Possible end effects for P-01 are seen on adjacent lines (lines 86+00 E and 88+00 E, around 29+50 N). Line 85+00 E should also be surveyed to look for a possible extension for P-01.

Other weak possible I.P. anomalies are seen, especially at the south limit of lines 89+00 E and 86+00 E. They should be detailed with the I.P. method to the south.

The resistivity low zones, related to ticker overburden, define a  $\pm$  east-north-east trend. An other resistivity low axis, interpreted as striking  $\pm$  north-south, could be associated to a fault (see on line 87+00 E, around 32+50 N). It is located near P-01. This "cross-cutting" feature may has its importance for possible mineralization.

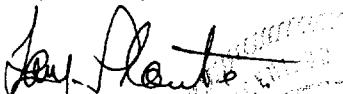

The time constant estimates we produced, must be taken with great care, since the survey is much noisy (due to the field conditions).

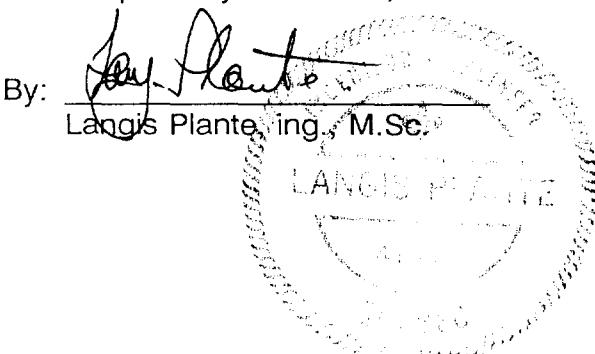

## CONCLUSION AND RECOMMENDATIONS

The induced polarization survey performed over the property had to be stopped because of difficult field conditions. The results are noisy. However, one well defined I.P. anomaly has been detected. This anomaly (P-01) should be verified by drilling, or possibly by trenching, if relevant. Other possible weak I.P. anomalies have been interpreted but other geoscientific data are needed to properly assess them.

The survey should be resumed during the summer or shortly after spring, in a period of time when the overburden is water saturated. Porous pots should also be used. This should improve future data quality. In the same time, the present data should be verified on a couple of lines to insure we did not miss anything (on line 87+00 E at least). Line 85+00 E should also be covered with I.P. in order to try to detect an extension for P-01.

## **STATEMENT FOR ASSESSMENT WORK**

I, the undersigned, Langis Plante, for **Géola Limitée**,  
certify to the following:

During the period of December 9th to 16th, 1997, an induced polarization survey (7,1 km) was done over a property owned by Cameco Gold inc.

The property is located approximately 21 km east-north-east of Sioux Lookout, in Sharron Lake and Zarn Lake townships, Ontario. The survey covered claim 1162704 ( $\pm$  252 hectares). The property can be reached using highway 642 east, for  $\pm$  17 km, and a skidoo trail for  $\pm$  15 km, up to Black Lake.

### Description of the I.P. method:

Transmitter: GDD 1400, 1,4 kW;  
 Receiver: BRGM IP-6;  
 Configuration: Dipole-dipole;  
 Separation: a = 25 metres, n = 1 to 6;  
 Interval: 25 metres;  
 TIME Domain;  
 Parameters: Resistivity and chargeability;  
 Cycle: 2 sec ± On, 2 sec OFF;  
 Integration: start: 0,16 sec; stop: 1,74 sec.

Operators:

#### 6. Instructions for cutting back credits that are not approved.

Some of the credits claimed in this declaration may be cut back. Please check (✓) in the boxes below to show how you wish to prioritize the deletion of credits:

- 1. Credits are to be cut back from the Bank first, followed by option 2 or 3 or 4 as indicated.
- 2. Credits are to be cut back starting with the claims listed last, working backwards; or
- 3. Credits are to be cut back equally over all claims listed in this declaration; or
- 4. Credits are to be cut back as prioritized on the attached Appendix or as follows (describe):

Note: If you have not indicated how your credits are to be deleted, credits will be cut back from the Bank first, followed by option number 2 if necessary.
